THE

JOURNAL OF HORTICULTURE, COTTAGE GARDENER,

AND

COUNTRY GENTLEMAN.

A JOURNAL OF HORTICULTURE, RURAL AND DOMESTIC ECONOMY, BOTANY AND
NATURAL HISTORY.

CONDUCTED BY

GEORGE W. JOHNSON, F.R.H.S., AND ROBERT HOGG, LL.D.

THE FRUIT AND KITCHEN GARDENS, by Mr. J. Robson, Gardener to The Lady Julia Cornwallis, Linton Park; and Mr. T. Weaver, Gardener to the Warden of Winchester College.

THE FLOWER GARDEN, by Mr. D. Beaton, late Gardener to Sir W. Middleton, Bart., Strubland Park.

STOVE AND FLORISTS' FLOWERS, by Mr. T. Appleby, late of Victoria Nursery, Uxbridge.

THE GREENHOUSE AND WINDOW GARDEN, by Mr. R. Fish, Gardener to Colonel Sowerby, Putteridge Bury, near Luton.

FLORISTS' FLOWERS and FLORICULTURE, by the Rev. H. H. Dombrain.

ALLOTMENT AND GARDENING CALENDAR, by Mr. William Keane.

POULTRY-KEEPING, by Mr. J. Baile, Rev. W. W. Wingfield, E. Hewitt, Esq., and other well-known contributors.

BEE-KEEPING, by H. Taylor, Esq.; T. W. Woodbury, Esq., "A Devonshire Bee-keeper;" "E & W.;" and Mr. S. Bevan Fox.

HOUSEHOLD ARTS, by the Authoress of "My Flowers," and others.

VOLUME II., NEW SERIES.

VOL. XXVII., OLD SERIES.

LONDON :

PUBLISHED FOR THE PROPRIETORS, 162, FLEET STREET.

1862.

1911. 11. 2

TO OUR READERS.

AN epicure—some say 't was Quin—
It matters not a single pin—

for "the point of the tale" is that, when rustivating on the southern coast, he was told, with his shaving-water, that there was no John Dory in the market. "Then I shall go to sleep again," was the reply; "call me to-morrow morning." Now, it so happens that there is no John Dory at our command at this present time—no laudatory letter deserving of being here blazoned—no stir-'em-up letter from Miss Penelope of Cackleton Hall requiring a rejoinder—yet we certainly do not incline to go to sleep, nor must we tell the printer to call again when another volume commences. Yet we cannot divine how we should have commenced, or what we should have said, O Reader, had not our eyes rested upon that most suggestive picture by Miss Gillies, "The Past and the Future."

In that picture the elder form, with pensive reflective face turned upon the background prospect, well impersonates the recent "past." That face indicates reflection gathering wisdom from events; bears the impress of regret that more was not accomplished during days gone by, and of sorrow for those taken from us during their continuance. The expression of that face well accords with private regret and sorrow for those irrevocable events; nor is it less expressive of the sorrow of our whole nation for the Leader we have lost—not merely the Leader of a Royal household, but a Leader in all things tending to the improvement of physical and intellectual life.

The heart feels relieved, and the eye brightens, as it looks upon the fair, smiling, upraised features of the other and more youthful figure in that picture. Those onward-looking features are indicative of good resolves, and beaming with hope that those resolves will be abundantly fruitful. They are emblematic of "the future" we are looking towards. We have resolved to be still more useful even than heretofore. In that "future" are to be fulfilled the promises of fresh aid; in it beneficial discoveries are to be revealed; we are aware of new illustrations to which it will give birth; and in that future the appropriate riches of the International Exhibition will have to be examined and reported.

So, we are hopeful, trustful, and powerful, not only because the approaching harvest is plenteous but because our harvestmen are vigorous and well-skilled. Nor do our causes for looking smilingly towards "the future" end there, because we are well assured that the samples from our garners will be above an average of excellence; and "the past" gives a guarantee that we shall obtain for them a ready sale.

INDEX.

- ABERDEEN POULTRY SHOW**, 225, 344
Abies, microserpa, 11; *Alcoquiana*, 461; *Williamsonii*, Douglasii, and *Canadensis*, 482
Acacia, 45
Acacia arabica, 45
Acanthus mollis, 44; of the Romans, 44
Achimenes, propagating, 362
Achilles odorata, potting, 375
Agapanthus umbellatus, dividing, 216; propagating, 176
Alliantus silkworm, 20, 465, 516
Air, mode of admitting, 216
Albert, Prince, death of, 251
Alyreodes, 71
Alyssum variegatum, propagating, 69
Amaryllids, cross-breeding, 309
Amaryllis formosissima seedling, 100
Amaryllis, bright, 303
Anacharis alainstrum, 177
Ancona fowls, 323
Animal carcasses as manure, 443
Annals, list of some sweet-scented, 485; sowing, 521
Ants, banishing, 363, 522
Apianian notes, 205, 427, 486
Apongeton, 374
Apple, the Melon, 32; dumplings, 40; scoop, the old, 320
Apple trees, from cuttings, 36; for small garden, 118; budding, 166; old, severely pruned, 281; pruning, 255, 303; layering, 383; largest in America, 471; espaliers, treatment of, old, 522
Apples, new use for, 47; for espaliers, &c., 136
Apricot, trees, unfruitful, 100; pruning, 318
Apricots under glass, 494
Artichoke as an ornamental plant, 5
Aquatics, water, treatment of water, 105; notes on a few tender, 378, 454
Arabis, cuttings of variegated, 31; propagating variegated, 522
Aranea injured by frost, 405
Arbor Vitæ hedge, border by, 253; plants under, 383
Archimedes' screw, 67
Arctostaphylos, sowing, 355
Aristolochia arifolia, 439; siphon for a wall, 424
Aristolochia Macqui, variegated, 127
Artichoke as an ornamental plant, 5
Ashes for meadows, 136
Asparagus, forcing, 153, 322; plants, old, removed, 405
Asphaltum, floor, to make, 36; walks, 65; walks, making, 445
Asters, sowing, 522
"Atlas, Imperial Library," 474
Australian Grass Parrots, and other Birds, 430
Australian Ivy, 176
Aviary, the, 288
Azalea, flowers, obtaining early, 126; leaves, 262
- BALCONY AND WINDOW PLANTS**, 303
Banana, variegated, 14
Balrath, 478
Banana culture, 50
Bantams, points in, 155; warming roost-house for, 328; legs of, 450; roost-house for, 526
Bark-horned trees, 242
Basket, plants for suspended, 445, 460
Baskets for poultry, 75
Beau culture, 433
Beans, Runner and Dwarf Kidney, culture, 455
Bedding-out plants, 54
Bedding-out and mixed-border planting, 61; plants in a greenhouse, 68
Bedding plants, propagating, 35; and bedding-out, 68; wintering in ainery, 132
Bedfordshire Poultry Show, 37
Beds under trees, 65
- Bee**—have queenless, 19; removing to a distance, 20; making swarm settle, 20; Lignurian queens, 30, 36; age of, 36; *W. W.* Overhampton in 1861, 39; drone iouffence, 39, 77, 158; age of queen, 39; notes on, 39; feeding of, 40; moisture in hive, 40; yellow-bellied breeding drones, 38; venting hives, 59; young expelled, 59; drones from old queens, 59; how I became a keeper in Oxon, 59, 268, 287, 327; season in Roxburghshire, 60; song of, 60; humble, their fertilis ion, 76; parthenogenesis in, 77; queen breeding drones, 77; uniting, 78; Lignurian misadventure, 78; note on, 79; parthenogenesis in foundation of queen, multiplication of Lignurian, 97; young expelled, uniting, "B. & W." apary in 1861, 98; uniting, 118, profit of; black with Lignurian queen; how I failed with the Phivians, 119; super-posed hive becomes the stock-hive, 139; queens expelled, 140; uniting, 144; season in Roxburghshire, 158; uniting, misadventure with hybridised queen, 159; super-posed hive does not become the stock, 179, 180; storing, 179; Lignurian process, parthenogenesis in bee and moth, 179; uniting, 180; feeding, propolis as a varnish, 180; does the super become queen, 205; art of queen-making, 205; bottle-feeding, 206; bar-and-slide hives, 208; super-posing, 22; Lignurian in Scotland, 227; parthenogenesis in, 228; dividing and uniting, aspect for, 228; solution of super-posing problem, 247; Lignurian, early-breeding, irregular production of drones, 247; corsairs, super-posing, driving, 248; art of queen-making, 267; Lignurian queens deserting hives, 268; late breeding of, 286; driving, 286; hive uniting in winter, 278; driving, uniting in bar-hives, 308; protection, 305; examining without being stung, 307; honey and chemistry, feeding in the comb, 307; irregular production of drones, queen's biting, interbreeding, super-posing difficulty, 326; apary in 1861, 346; super-posing, 348; queen's bite, unfiled hives, 318; winter temperature, evers, Lignurian, 367; interbreeding; super-posing; in Ceylon, 368; early pollen gathering, 382; development of hives, ventilation, Lignurian queen, 386; temperature of queen, 397; Lignurian as honey-gatherers; Oxfordshire bee-keeping, 409; honey, chemistry, 410; sugar for feeding; early pollen-gathering, 426; cross with Lignurian; chemistry of honey, in East Indies, effects of interbreeding, 428; super-posing, common and native in Australia, 429; size of hives, &c., 430; natives of England; Welsh laws about, as chemists, super-posing difficulty, 447; uniting, 448; what the bee said; honey harvest in Australia, 449; loss of Lignurian; super-posing, uniting, 467; rapid multiplication of Lignurian, 488; dying of thirty, 489; 487; artificial Lignurian queen, 488; steering, 488; winter ventilation, 505; Lignurian management; putting to a frame-hive, 507; hives facing east, 507; Lignurians in Australia; distance they fly, 518; unable to fly, 508; Lignurian, uniting, 524; as chemists; its fertilisation, injurious to Woodbury, 525; Lignurian in Podolia, 526
- Beech**—have queenless, 19; removing to a distance, 20; making swarm settle, 20; Lignurian queens, 30, 36; age of, 36; *W. W.* Overhampton in 1861, 39; drone iouffence, 39, 77, 158; age of queen, 39; notes on, 39; feeding of, 40; moisture in hive, 40; yellow-bellied breeding drones, 38; venting hives, 59; young expelled, 59; drones from old queens, 59; how I became a keeper in Oxon, 59, 268, 287, 327; season in Roxburghshire, 60; song of, 60; humble, their fertilis ion, 76; parthenogenesis in, 77; queen breeding drones, 77; uniting, 78; Lignurian misadventure, 78; note on, 79; parthenogenesis in foundation of queen, multiplication of Lignurian, 97; young expelled, uniting, "B. & W." apary in 1861, 98; uniting, 118, profit of; black with Lignurian queen; how I failed with the Phivians, 119; super-posed hive becomes the stock-hive, 139; queens expelled, 140; uniting, 144; season in Roxburghshire, 158; uniting, misadventure with hybridised queen, 159; super-posed hive does not become the stock, 179, 180; storing, 179; Lignurian process, parthenogenesis in bee and moth, 179; uniting, 180; feeding, propolis as a varnish, 180; does the super become queen, 205; art of queen-making, 205; bottle-feeding, 206; bar-and-slide hives, 208; super-posing, 22; Lignurian in Scotland, 227; parthenogenesis in, 228; dividing and uniting, aspect for, 228; solution of super-posing problem, 247; Lignurian, early-breeding, irregular production of drones, 247; corsairs, super-posing, driving, 248; art of queen-making, 267; Lignurian queens deserting hives, 268; late breeding of, 286; driving, 286; hive uniting in winter, 278; driving, uniting in bar-hives, 308; protection, 305; examining without being stung, 307; honey and chemistry, feeding in the comb, 307; irregular production of drones, queen's biting, interbreeding, super-posing difficulty, 326; apary in 1861, 346; super-posing, 348; queen's bite, unfiled hives, 318; winter temperature, evers, Lignurian, 367; interbreeding; super-posing; in Ceylon, 368; early pollen gathering, 382; development of hives, ventilation, Lignurian queen, 386; temperature of queen, 397; Lignurian as honey-gatherers; Oxfordshire bee-keeping, 409; honey, chemistry, 410; sugar for feeding; early pollen-gathering, 426; cross with Lignurian; chemistry of honey, in East Indies, effects of interbreeding, 428; super-posing, common and native in Australia, 429; size of hives, &c., 430; natives of England; Welsh laws about, as chemists, super-posing difficulty, 447; uniting, 448; what the bee said; honey harvest in Australia, 449; loss of Lignurian; super-posing, uniting, 467; rapid multiplication of Lignurian, 488; dying of thirty, 489; 487; artificial Lignurian queen, 488; steering, 488; winter ventilation, 505; Lignurian management; putting to a frame-hive, 507; hives facing east, 507; Lignurians in Australia; distance they fly, 518; unable to fly, 508; Lignurian, uniting, 524; as chemists; its fertilisation, injurious to Woodbury, 525; Lignurian in Podolia, 526
- Beet** culture, 433; novel use of, 450
Begonia Kunthiana, 357
Begonias, treatment of large, 262; culture of variegated, 452
Birds, and insects, 228; destruction of small, 327; and buds, 376; keeping in hives, 463; talking, 506; keeping useful and ornamental, 523
Birmingham Poultry Show, 74, 75, 156, 202, 223, 246; sales, 266, 586; Judges at, 304
Bleeding in Birch trees, 504
Blossoms on dwarf trees, protecting, 74
Boiler, what it can heat, 242; heat in, 240, 374
Boilers, setting correct, 394
Bolbophyllum harbigicum, 358
Border plants, some gay, 464
Bolets of the Romans, 2
Bones, for manure, 176; reducing to powder, 333
Borage flowering, 262
Borders, striped, and suitable plants for, 400; one-sided striped, 416; staid in, 420, 422
Borecole culture, 433
Bottom heat, 341; obtaining, 363
Bouquet, criticised, 77; wedding, 46; of foliage, 92
"Bonquet, the Illustrated," 312
Box-edging, 477; planting, 363, 423; cutting, 484
Brahma Pootra, points in, 154
Brunca ursina, 44
Bridemonth Poultry Show, 17
Brocchi culture, 455
Broomhorozh Pool Works Horticultural Society, 111
Brown stock, 321
Bronchitis in fowls, 117
Brussels Sprouts, propagating, 174; culture, 433
Buckwheat, sowing, 55
Buds, care in brushing off, 217
Bulb culture, 54
Bulbs, watering potted, 31; starting, 68; to flower in January, 89; forcing, 123; treatment of Cape, 302
Buable feet in poultry, 420
Bunium denudatum, 92
Burmah, garden in, 474
Butter free from turnip taste, 255; per pint of cream, 488; turnip-flavoured, 526
Buttercups in a pasture, 522
Bythia holifera, 578
- CABBAGE CULTURE**, 13, 456; **INSECT ONES**, 13
Cages, preserving white-hearted, 95; checking growth of, 153; sowing cacti, 381, 440
Cachet's nursery, 351
Cacti, Lilliputian, 281; cross-breeding, 281
Cactuses, 201
Caged birds, food for seed-eating, 139
Caes, construction of, 157; for breeding, 208; colouring the wires of, 288
Calcatoria cuttings, 3, 241, 505; seedlings, 105; wintering, 116; culture, 116; violacea, 358; arachnoid, 416; cuttings midwived, 522
Calcatorias, cross-breeding, 314
Californian crosses, 481
Calla ethiopica, double, 504
Calne Poultry Show, 92
Calves, fattening, 526
Camellia—flowers, obtaining early, 126; and its culture, 188, 392, 574; seedling, 201; in a dwelling, 201; cactx falling, 280; flower-buds falling, 262; repeating, &c., 392; habit of some, 393; characteristics, culture, and varieties, 410; culture, temperature, &c., 491; bulb not opening, 522
- Camellias**, blooming prematurely, 66; cross-breeding, 359; buds growing slowly, 346; in France, 351; treatment of old, 458; buds turned brown, 460
Campagna grandiflora, 278
Canneries, food for, 288; in a greenhouse, 349; at the Crystal Palace, 380; pairing and breeding, 425; rearing and teaching, 465; feeding young, 468

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 63.4° and 43.8° respectively. The greatest heat, 80°, occurred on the 30th in 1834; and the lowest cold, 27°, on the 2nd in 1853. During the period 113 days were fine, and on 125 rain fell.

FLORA OF THE ROMAN CLASSICS; OR, CATALOGUE OF PLANTS MENTIONED BY LATIN AUTHORS, WITH AN ATTEMPT TO IDENTIFY THEM.

(Continued from Vol. I., page 473.)

TUBERS.

THE appearance in your Journal of a very interesting paper on the "Flora of the Roman Classics," induces me to ask if the learned contributor of that article can inform his readers what product of the garden Petronius alludes to in one of his satirical descriptions of the approach of age in the "Tuber horti quod creavit unda." The passage is to be found at page 651 of this author's writings as follows:—

"Infelix modo erinibus nitibus, Phœbo pulchrior et sorore Phœbi; Ad nunc levior ære, vel rotando Horti tubere, quod creavit unda, Ridentem, fugis et times, puellas."

(Unhappy one! formerly brighter than Phœbus or than the sister of Phœbus, you looked beautiful with your hair; but now [your head is] more smooth than brass, or than the globular Garden Tuber, which rain has brought forth, and you fear and flee from the scolding girls.)

It has by some been referred to the Tuber terre, the Cyclamen or Sow-bread (*Cyclophorus*): but it cannot be said of the Cyclamen that it is produced by floods.—W. R. BASHAM.

There are three kinds of Tubers mentioned by the Roman writers—the Tuber, which was a tree, and the "Tuber horti," or "Tuber terre," mentioned under both names by Petronius and others.

Of the Tuber we have this history from Pliny:—"Æque peregrina sunt zizipha et tuberes, quæ et ipsa non pridem vendere in Italiam, hæc ex Africa, illa ex Syria. Sextus Papinius, quem Consulem vidimus, primus utraque attulit, Divi Augusti novissimis temporibus, in castrorum aggeribus sata, bacis similia quàm malis, sed aggeribus præcipue decora quoniam et in tecta jam silvæ scandunt. Tuberum duo genera; candidum et a colore sericum dictum." (The Jujube trees and the Tubers are alike exotics, which, indeed, have but recently come into Italy, the latter out of Africa and the former out of Syria. Sextus Papinius, whom we have seen Consul, first introduced both of them in the latter part of the reign of the Emperor Augustus, having planted them in raised beds within his camps. The fruits are more like to berries than to Apples. They are chiefly ornamental, grown upon raised beds [terraces], and woods of them clamber upon houses. Of the Tubers there are two kinds—the white, and that from its colour called sericum [serinum? waxen yellow].—*Nat. Hist.*, xv., c. 14.

That the Tuber came from northern Africa and was No. 27.—VOL. II., NEW SERIES.

improved by culture we have the testimony of Martial, who says—

"Læta suburbanis mittitur apyrina ramis, Et vernæ tuberes: quid tibi cum Libyæ?"

(Tubers with soft kernels and home-grown are sent to you from suburban trees: why do you require those from Libya?)—*Epig.*, l. xiii., 42-43.

Libya was the portion of Africa bordering on Egypt, but frequently was extended by the poets to include Carthage. In the same epigram Martial mentions that these stoneless Tubers came from Nomentum, a town of the Sabines, and not far distant from Rome. According to Seneca the term *apyrina* did not imply that there was no hardness in the kernel, but only less hardness.—(*Seneca's Ep.*, 85.)

Of the same tree, for tree it evidently appears to have been, Pliny further says, after directing the Zizyphus to be raised from seed, "Tuberes melius inseruntur in pruno sylvestri, et malo cotoneo, et in calabrice, ea est spina sylvestris." (The Tubers are better grafted upon the wild Plum, the Cotoneaster, and the Calabrix, which is a wild Thorn.)—*Ibid.*, xvii., c. 10.

In that passage Pliny evidently intimates that they may be sown like the Zizyphus, though grafting is to be preferred, and Palladius states the same. He says—"Nunc (Februarius) tuberes seruntur et inseruntur." (Now, February, Tubers should be sown and grafted.)—*De Re Rustica*, iii., c. 25.

In a subsequent chapter he is still more particular, as follows:—"Mense Septembri circa Kalendas Octobres, vel Februarius tuberes seremus sobole, vel nucleis, cuius tenera diligenter nutrirî debet infantia. Sumatur cum radicibus planta divulsa; bubulo solum liuatur ac luto: statuantur pingui terra et subacta, subditis cochis, et marina alga: terris magna sui parte condatur. Alii pomis statim grana decussa et sole siccata, pingui et prope cribrata terra, auctumno tria simul ponunt, quæ feruntur in unum coire virgultum: quod assidua rigatione juvandum est, atque fossura, quæ solum leviter scalpens teneritidum robur inducat, post annum deinde, vel aliquanto tardius, quæ fuerit de semine planta, transferetur: et hoc genere fructus efficit dulciores. Mense Januario ultimo vel Februarius tuberum surculus mirabiliter proficit cydonio insitus, inseritur autem malis omnibus, et piris, et prunis, et Calabrice melius trunco fisso, quam cortice, desuper qualo vel fictili vase munitur, repletis usque prope summitatem surculis terra subacta cum stercore. Prostant tuberibus, quæ malis prodesset memoravi. Tuberes servabuntur, si obruantur in milio, vel urceolis picatis et oblitis." (In the month of September, about the Kalends of October, or in February, we propagate the Tuber, either from a sucker or from kernels. Its tender infancy should be diligently nurtured. Let the plant be taken up with its roots, smeared with cowdung and clay, planted in rich, well-worked soil, with shells and sea-weed placed beneath, a chief part of it should be buried underground. Others in autumn sow three seeds together, that have been shaken from the fruit and dried in the sun, sowing in rich, well-sifted earth. They are said to unite and produce one

No. 679.—VOL. XXVI., OLD SERIES.

stem. It must be assiduously watered, in which it delights, and the soil be dug around and lightly scarified, which will bring strength to the tender plant. A year afterwards, or rather later, the plant raised from seed is transplanted, and this produces superior fruit. At the end of January, or during February, a graft of the Tuber inserted on the Quince thrives exceedingly. It is grafted also on all Apples, Pears, and Plums, and on the Calibrix, with more success in the cleft trunk than in the bark.* It is enclosed in a basket or earthen vessel filled to above the graft with earth well mixed with dung. Those things are beneficial to Tubers which I have recorded as being beneficial to Apples. The fruit of the Tubers will be preserved if buried in Millet seed, or in small vessels pitched and well closed.)—*Ibid.*, x., c. 14.

Now, the question to be solved is, What is the modern name of the Tuber tree? To guide us to a correct answer we have these facts—It was a native of Africa; probably resembled the Jujube tree, for it is repeatedly mentioned in connection with it; it was graftable upon the Apple, Pear, and Thorns; it was probably evergreen, because grown against houses; the fruit was eatable, and even agreeable, and capable of being preserved.

To all these characteristics agrees *Rhamnus spina Christi*, or, as it is now called, *Zizyphus spina Christi*. This tree is a native of northern Africa, Barbary, Egypt, and Palestine, the very localities best known to Sextus Papinius. It is not only of the same natural order (Rhamnaceæ) as the Jujube, but is now included in the same genus. It is graftable upon some, if not all the stocks stated by Palladius; and we may remark that if it failed in some it would not be surprising, for promiscuous grafting was one of the delusions under which most of the Roman writers on gardening laboured. It is an evergreen, and peculiarly suitable for the sides of houses, the leaves much resembling those of Ivy. The branches are round and pliant, and being furnished with many sharp spines, calculated to give pain. Haselquist thinks that the crown of thorns put upon our Saviour's head was probably formed of them: hence the specific name of *spina Christi*. The fruit is an oblong drupe, the size of a small plum, enclosing a roundish nucleus or stone, and is said by Desfontaines to be eatable and pleasant. Like those of the Jujube, they improve by being kept.

It was not to the tree Tuber that Petronius alludes under the name of Tuber horti.

In the passage quoted by our correspondent the satirist makes one of his acquaintances, Eumolpus, ridicule the loss of hair which he, Petronius, had sustained. The passage has been thus rendered in English verse:—

"Beauty's chief ornament, your hair, is lost:
That vernal grace has felt autumn's frost;
Your naked temples mourn their ravi'sh'd shade;
Waste as a stubble field your pate is laid;
Ere the sun's gold'ns' how swift thy fates our bloom!
The gifts you first bestow you first resume.
Unhappy man! charms did once surround
Your head with shining tresses crown'd,
So bright that far less brightly glister
The locks of Phœbus on his Easter.
Now all is chang'd, and in their stead,
Polish'd as brass, appears your head
Like a fresh Mushroom, round and bright,
And seoff'd by girls you take to fight."

Every one must have noticed how often the pilus, or cap, of the Mushroom is a miniature model of a bald head. Nor is the resemblance much less in some of the freshly-dimterred Truffles.

We have the authority of Martial that the term Tuber was applied to the Mushroom, at all events by the poets, for he has these lines—

"Rumpinus altricem tenero que vertice terram
Tubera, boletus poma secunda sumus."

* Columella, book xi., c. 2, agrees in stating that the grafting should be in January.

* A French translation, published at Amsterdam in 1756, has rendered two of the concluding lines thus:—

"Ton crâne aussi poli qu'aucun métaux peut l'être
Es-semble un champignon qu'une pluye a fait naître."

(We, Tubers, who with tender head break through our mother earth, are second only to the Boletus.)—*Epiq.*, l. xiii., 50.

Now, the Truffle never does break through the surface, but is strictly a subterranean fungus. What fungus was known to the Romans as the Boletus we need not here digress to determine; it was evidently in high esteem, for Juneval says—

"Vilibus anicipites fungi donentur amicis,
Boletus domino."

(Uncertain fungi are given to friends of small esteem, the Boletus to the master.)

Pliny speaks of Tubers as follows:—"Et quoniam a miraculis rerum cepimus, sequemur eorum ordinem, in quibus vel maximum est, aliquid nasci aut vivere sine ulla radice. Tubera hæc vocantur." (Since we have begun concerning the wonders of nature we will follow them in order, and among the chief is that any plant should be either produced or live without a root. Such are those called Tubers.)—*Not. Hist.*, xiv., c. 2.

That Pliny meant the Truffle there can be no doubt, for at considerable length he proceeds to describe these Tubera in words which have been thus translated by Dr. Bostock and Mr. Riley:—

"Truffles generally grow in dry, sandy soils, and spots that are thickly covered with shrubs; in size they are often larger than a Quince, and are found to weigh as much as a pound. There are two kinds of them; the one full of sand, and, consequently, injurious to the teeth, the other free from sand and all impurities. They are distinguished also by their colour, which is red or black, and white within; those of Africa are the most esteemed. Whether the Truffle grows gradually, or whether this blemish of the earth—for it can be looked upon as nothing else—at once assumes the globular form and magnitude which it presents when found; whether, too it is possessed of vitality or not, are all of them questions, which, in my opinion, are not easy to be solved. It decays and rots in a manner precisely similar to wood.

"It is known to me as a fact, that the following circumstance happened to Lartius Licinius, a person of pratorian rank, while minister of justice, a few years ago, at Carthage in Spain; upon biting a Truffle, he found a denarius inside, which all but broke his fore teeth—an evident proof that the Truffle is nothing else but an agglomeration of elementary earth. At all events, it is quite certain that the Truffle belongs to those vegetable productions which spring up spontaneously, and are incapable of being reproduced from seed.

"Of a similar nature, too, is the vegetable production known in the province of Cyrenaica by the name of 'misy,' remarkable for the sweetness of its smell and taste, but more fleshy than the Truffle; the same, too, as to the Iton of the Thracians, and the Geranton of the Greeks.

"The following peculiarities we find mentioned with reference to the Truffle. When there have been showers in autumn, and frequent thunder-storms, Truffles are produced, thunder contributing more particularly to their development; they do not, however, last beyond a year, and are considered the most delicate eating when gathered in spring. In some places the formation of them is attributed to water; as at Mytilene, for instance, where they are never to be found, it is said, unless the rivers overflow, and bring down the seed from Tiara, that being the name of a place at which they are produced in the greatest abundance. The finest Truffles of Asia are those found in the neighbourhood of Lampascus and Alopeconnus; the best in Greece are those of the vicinity of Elis."

The opinions that the rain and the overflowing of the river gave birth to the Truffle agrees with the sentence in Petronius Arbiter.—G.

WINTERING CUTTINGS OF BEDDING GERANIUMS,

CALCEOLARIAS AND DIANTHUSES—OBTAINING BOTTOM HEAT.

The very end of September and the first half of October is about the very best time for planting cuttings of all the bedding Geraniums, where the greatest number is to be kept over the winter in the smallest space, and I was going to say with the least trouble. But when one begins to talk about trouble, it is high time for that one, and for all of his or her clan, to give up all ideas of keeping any plants through the winter, be they bedders or be they not.

The best cuttings of Geraniums are the very tops of the weakest shoots, and all the tops of very stunted plants, or such as may have been hard up for the last month for want of water or free room at the roots.

I once saw an operation worth talking about. The family left for the long vacation, and the gardener, or the man who did the garden, rooted out all the Geraniums before the middle of September. One of them was a seedling raised and flowered that season in the same garden, and they set a store by it, as the saying is, but the man forgot all about it for a month. It was then the middle of October. He had to hunt for it outside the garden; found it—a very large plant, all but quite shrunk up; but he took it in and took off all the tops for cuttings not much over 3 inches long. They, the cuttings, took a very long time to root, but they all did root, and that man says to this day October is the right time to "put down" cuttings for the winter.

After the beginning of October it is too late to make cuttings of Verbenas or Petunias. I mean too late for such people as I am writing to at present. There is nothing that will pay for the trouble to them now but Calceolarias; and all good bedding Calceolarias begin to root now on their own account from the back of the shoots nearest to the ground, and unless it was not a hard time of it, they would go on and improve in this their natural way of rooting till Christmas, and good, soft little cuttings of them will do well enough to be put in under a hand-glass till that time. But the luxury of a hand-glass is not within the reach of every one who reads my letters—I cannot yet afford to have one hand-light myself. But I have lots of tops and stops, which answer just as well for propagation, at ten times less cost and bother. The top parts of flower-pots without the bottom, and that to be turned upside down, will give the best idea of my tops; but drain earthenware-pieces of from six inches to a foot in the bore or barrel are better than flower-pots with the bottoms knocked out with a hammer, and short pieces of such pipes are better than the best hand-glasses in the world for striking autumn cuttings; and the reason why they are better is this—you can place them in front of a south window, or on the south side of a house, or castle, or anything where the sun comes the strongest, and, of course, the hottest part about a place, and there you can put down your cuttings in the middle of the dog days with less risk of suffering than if they were under a hand-glass behind a house, or wall, or castle, or fence, or dyke. The sun cannot touch them, the earthenware things get hot as iron bars, and the damp from the watering rises and makes it exactly like the top heat of a very sweet hotbed in the spring. A square of glass is the stop to keep in that heat for the use of the cuttings.

You never saw how easy all the new Pinks or Dianthus tribes do in and under my tops and stops; and that reminds me that I made a tremendous mistake in the beginning of this letter, when I said that nothing would do much good for out-door cuttings except Calceolarias after October is once in. Why, I shall have to put in scores of cuttings yet of many sorts of Dianthus. Capt. T. Clark's hybrids, single and double, are the very best yet in existence. I never saw such loads of cut flowers as I cut this season of his single kind. I had only one stool of the double of this strain. I had it from Dr. Lindley's garden through Mr. Booth, our late Secretary to the Horticultural Society, and it must be true. Then I ordered a plant of Dianthus hybridus multiflorus, or double winter-flowering sort, which is figured in the "Illustrated Bouquet;" but I first saw it at the Floral Committee this time last year, and seeing it to be such a first-rate flower I sent for it at once, and now I have a dozen of it, and I shall put in every morsel of cutting the plants will make till the end of November.

But I found out a way for making a damp hotbed, or bottom heat in summer, at no cost. I can have a damp bottom heat on

the leads or on the window-sills of the highest house in London, and my tops and stops will strike cuttings outside the window facing the sun in the middle of July, August, or September without shading in the least, and the bottom heat will rise or fall of itself, according to the light there is for the cuttings. The plan will also grow Geraniums and Fuchsias, with many other kinds of plants for the shows. It is a grand thing to have moist bottom heat for a plant the whole summer, and the top to be out in the open air all the while. It is as good as the geothermal system of old English gardeners—*not* the dry destroying heat from heating a bed of earth as M. Naudin very foolishly recommended in his pamphlet. I kept the plan quite a secret till I made sure of it myself. Then one of the best practical men of our day called, and was delighted with the idea of it.

Mr. Marnock, of the Regent's Park Botanic, was the first person who ever recommended growing plants in double pots; and Mr. Eyles, of the Crystal Palace, was the first who proved to the public, and in a public way, that plants could be grown on the surface of water the year round more easily than in any other way in the same arrangement of house-room. Now my plan for bottom heat on the top of a house embraces the essence and the two best points in the double-pot system, and in the plan of growing plants standing on the surface of sheets of water. You can understand how plants rest on the surface of water if you suppose in the country a four or nine-gallon cask to be put down in a horse-pond till the top end was just level with the surface of the water, then you would put a pot Geranium on the end of the cask; then, of course, the bottom of the pot was just on the top of the water, and the roots could then suck and be constantly full of sap.

Now, just look at this. Suppose I put your Geranium-pot inside a bigger pot, as Mr. Marnock recommended, and suppose your pot did not reach the bottom of my empty pot by 2 inches, because the rim of your pot rested upon the top of my pot, and made your pot hang, as it were, inside my pot. Now, that is the new dodge. Where the tops of the two pots join issue for the hanging of the inside one, I run a bit of putty or puddled clay, as for grafts, to make the part perfectly air-tight. The plan hinges on the perfection of the air-tightness between the rims of the two pots. Now, with this putty on and dry, place them on the top of the cask in the pond again, and push in the cask till the water is 2 inches deep over it; the water will then be level with the bottom of the inner pot, and it rests, as it were, on the surface of water just like Mr. Eyles did his basin plants at the Crystal Palace. Instead of a beer-cask to stand the double pot on, suppose you put it in a hand-basin, with water enough to rise to the bottom of the inside pot, or nearly so; or a soup-plate might do; but a deep garden-pot saucer is the best of all, and if you keep the saucer full the whole summer, the heat of the outer pot from the heat of the sun will cause the air which is between the pots to suck up the water, and vapour will rise of itself from the heat; but neither the heat nor the moisture can escape from between the two pots, owing to the stopping with putty or soft clay. Then the inside pot is hanging in a vapour-bath all the summer. The roots next the side of the pot never get quite dry, even if you did not water the pot, because the inside pot itself is constantly as wet from the vapour as if it were in a pond, and the roots stick to any moist surface like that.

I have struck many sorts of cuttings and grown several plants of different families of plants by this simple plan, and I am perfectly satisfied some of you will make wonders to cease in the simplicity of the growing and rooting systems, by some improved method of applying the thing inside as well as outside all manner of houses, hothouses included. Hang up a plant to the ridge of a Pine-stove, and it may thus enjoy damp bottom heat the whole summer. Ferns, in double pots, potted and put in saucers of water after being potted in nine-parts of cocoa-nut refuse, and one-part yellow maiden loam—the proper proportions for most Ferns which do not rise above 15 inches or 18 inches high—I say Ferns treated that way would astonish Mr. Sims himself. There is nothing in which the finest Ferns will grow nearly so easily as in that very compost, and no drainage to the pots either, except a little of the fibres, of which there is a due proportion in every measure of the refuse. But, say cuttings instead of Ferns, and we shall be nearer perfection. Every plant will root in it faster and more to its liking than in any other thing I ever saw tried.

I was amused the other day on receiving some rare plants from near Bristol, from a rev. gentleman there, all grown in our

Kingston cocoa-nut refuse stuff; and if you could see the vigour of *Sibhorrpia europea*, the most delicate of European growth, you would not wonder at my earnestness.

If I was young again I would undertake to beat Mr. Turner at all the shows with this way of bottom heat to Pelargoniums, and I would never give a drop of strong water to the top of a pot Geranium, but would supply it in vapour from below. My cuttings would be all struck that way out of doors. I mean the cuttings of all common pot plants, as *Fuchsias*, *Cinerarias*, *Mimulus*, *Verbenas*, *Petunias*, *Geraniums*, and all; so that from the cradle they would be accustomed to the system. Just consider yourself the difference there must be between a collection of plants reared this way without as much as a newspaper shading on any of the cuttings from first to last. Again: the plan, I am persuaded, will be found just as useful in doors as in the open garden—I mean in living-rooms. Any plant one could bring into a drawing-room where the air is very dry during the winter on account of the fires, and more particularly Ferns, would do all the better by having the pot thus protected from the thirsty air of the rooms. In great houses they do this as part of the routine, but not quite so effectually as it might be done. They plunge the pots in china jars or in some ornamental vases, or things of that kind, and then with very green moss they muleh the surface as it were—a most excellent plan, and if the moss was made to fill the top of the open space between the vase and pot very tightly, it would be much better than stuffing in grass all the way down between them.

The great want is to have warm air well retained round the flower-pot, and there would be sufficient moisture for the air from the drainage. But a common flower-pot and a common empty pot of the same kind would keep any plant as safe as a gold vase, if the two rims were made air-tight as in my out-door propagation this very season. We shall say double potting is very good indeed, both in summer and winter; but an air-tight cavity between the two pots has four times more of the advantage resulting from the practice of double potting. We all know the use and value of pillow-cases. What would you say if one were to order flower-pot cases to be made on purpose for this very thing? Many a worse contrivance has been in practice in my time; but I mean to get some pillow-cases for my propagating-pots in the open ground. The price of a couple of hand-glasses would set me up for all my wants; and Mr. Robert Brown, of Stribton, the inventor of the ridge tiles on the Houses of Parliament, and so common now about London, would soon get them up to my sizes and capacities in his pottery here. The cases would be merely upright pots without bottoms, and I could use them constantly in two ways—put some of my best seedlings in pots, case and putty, and put them on water; or make a ring with the top or bottom of a case on the south border, fill within the ring with cuttings, put the case over the cuttings, and a piece of glass over the top, and what would be the difference between that and my tops and bottoms? I shall call this “The Cultivation and Propagation for the Million,” and whenever I shall hear of a practical gardener taking to the thing, I shall warn him off and tell him plainly to stick to his hotbeds, or try the geothermal plan, or anything but this. D. BEATON.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 24.

FLORAL COMMITTEE.—When firing that casual shot about the bedding-out at Kensington Gore, and the immense labour there seemed to be bestowed upon it, I had in my mind a very simple matter, which I will explain presently, and I can assure “F. R.” that the reference to the doings of the past was prompted by the feeling that I share with many others, that the old heaven is not eradicated yet. That the Royal Horticultural Society has made most rapid strides in public favour the we can be no question; that it has taken many steps well calculated to advance it in that respect is also patent. The appointment of such men as Mr. Murray and Mr. Eyles as its managing powers, the establishment of the Floral and Fruit Committees, the popular character of its exhibitions (so different from the exclusiveness of former days), all augur well; but there are still those connected with it, of whom to say the least, the public is somewhat shy of trusting; and already, as perhaps “F. R.” is aware, a considerable sum beyond the original estimate has been expended. However, as they have such a large accession of members, possibly the diffi-

culty will be to know what to do with their money. Nor should I have probably alluded to it but for this reason:—I believe it is intended that it shall be not only a show but a model place; and that noblemen and gentlemen from all parts of the kingdom will visit it, and, most likely, desire something of the kind to be done in their own place.

Now I know a little of what comes of this. My lord goes into the garden at Belleville, calls the gardener and says, “Harris, I saw the gardens at Kensington Gore the other day, and should very much like to know why I can't have mine as good.” If Harris ventures to suggest that it requires a great deal of labour he is immediately pool-pooled; for although my lord cares not how many pounds he expends to preserve his game, he grudges every one expended on the ornamental part of his grounds at any rate; and therefore I think it is only but just fair to let good folks know what really is the labour required to keep such a garden in trim, and to suggest that it is not qualified to be a model garden; for that we must look to the Crystal Palace, Kew, or (as Mr. Beaton seems to speak so highly of it), Hampton Court.

And now, having exonerated myself from the charge of unfairness, I hope, the Floral Committee may be reported. The subjects sent in for examination were few in number.

From Mr. G. McIntosh came *Lophospermum grandiflorum* coccoinea, not unlike Jacksoni, and not considered distinct enough to merit any award.

From Mr. Hanley, gardener to Sir Culling Eardley, came *Oxalis tropaeoides*, which was stated to have been purchased under that name in Russia. The foliage is dark and the habit dwarf, well calculated for an edging; but it was recognised as an old plant, its true name being *Comniolata rubra*.

Mr. Salter, of Hammersmith, sent some interesting subjects—viz., *Geranium tetragona*; *Weigela rosea variegata*; *Arabis procurrens foliis variegata*, a pretty rock plant; *Fuchsia corymbiflora foliis variegata*; *Vaccinium vitis-idaea foliis variegata*, a very pretty dwarf shrub, well calculated for the edging of an American bed—for this a Label of Commendation was awarded; and *Mentha heterophylla foliis variegata*.

Mr. Kinghorn, of Richmond, sent a very curious plant—*Angiozanthus Mangelsii*, which had been forwarded to him by the Very Rev. George F. Pownall, Dean of Perth, Western Australia. It is by no means a new plant, having been figured years ago in Sweet, but it is very striking: we hear sometimes people exclaim in looking at a flower, “How like *w.x.*!” This really looks as if it had been cut out of cloth, and the back of the flower-cup almost looks like the tags on a soldier's shoulder-knot. The colour is a bright green and brilliant scarlet, and, we doubt not, will prove a very great favourite with ladies. It is said to be difficult of cultivation; but these difficulties are now vanishing, and the skill that has made the *Disa* bloom will probably make the *Angiozanthus* hold its own in winter, when it is said to “fog off.”

Messrs. Chater & Co., of Braintree, sent a seedling bedding Dahlia, called King of the Dwarfs, about whose merits the Committee were divided; but I rather think it will turn out to be something good yet.

From Mr. Saunders, of Reigate, came *Echeveria ibiflora*—a very curious succulent plant, with a beautiful purplish-mauve tint. For this a First-class Certificate was awarded.

Mr. Charles Turner, of Slough, sent *Paldia* M's. Bush, a very beautiful light rose, of good form, great smoothness of petal, and well up in the centre—for this a First-class Certificate was awarded. He also sent a magnificent bloom of Pope's Earl of Derby, a flower of very great substance and great depth, for which a First-class Certificate has been already awarded; also *Ensign*, red, too small, and which some one slyly said was evidently not “bumpish.”

Mr. Wheeler, of Westminster, sent also one, very rough, and without a single good property.

From Mr. Day, of Tottenham, came a species of *Ladia*, with nothing of novelty about it. And lastly, from the gardens of the Society, a fine Fern—*Cyrtoneium caryotideum*, to which a First-class Certificate was given.

Previous to the Committee breaking up, a resolution was passed unanimously in reference to the omission from the schedule of the present year of certain florists' flowers—Tulips, Pinks, Pansies, Carnations, Picotees, Verbenas, and Ranunculuses, and suggesting to the Council that they be included in that for 1862. This has plainly been an omission in this year, and, I have no doubt, will be gladly remedied.—D., *Deal*.

SUCCESSFUL BEDS.

I QUITE agree with a correspondent in a late Number who praised the Geranium at the expense of the Verbena as a bedder. If the soil is rich and beds large so that you can peg perpetually and keep Verbenas growing they are all very well; but in small beds in small gardens, where the soil is kept poor to prevent rampant growth in the Geraniums, and the room is stented, Verbenas will not do at all. They make a splendid show for one month (August), but neither before nor after are they good for much. Purple King is the best, but his attempts at continuous blooming are very poor unless there is continuous growth. If Mr. Beaton can raise a Geranium to supply the place of Purple King, he will certainly deserve a peerage and be created Baron Beaton or Duke of Sarbiton. In white Verbenas Mrs. Alford is better than Snowflake; she is more dwarf and produces finer trusses. It is most desirable, if possible, to be independent of Verbenas in small gardens, Geraniums are so much more easily dealt with in winter and so much more continuous in bloom. Bijou must do instead of white Verbena. But, alas! there is nought to put in the place of Purple King. What will Madame Cuslag do? Amongst the whites what a beautiful thing is Madame Vaucher. I have not yet bedded it, but its trusses are bold and habit perfect: its growth about the same as that beautiful gem Christine. I observe that Frogmore is not to be distinguished from Crystal Palace or Trentham Scarlet: their habit is precisely similar, and time of bloom the same. Tom Thumb beats them both to nothing in July, but they beat him as completely now. Tom must be kept for the earliest bloom, and Frogmore or Crystal Palace for the later. Punch, if his constitution was not quite so robust, would beat both. I have good beds this year with the following combinations, the first named being in each case the centre:—Purple Nosegay, Flower of the Day, Little David, and Lobelia; Crystal Palace, Purple King, and Cerastium; Countess of Warwick and plum-coloured Verbena Ariosto; Brilliant and Purple King. A long bed of Cerise Unique with a strip of Ageratum down the centre, but not quite to each end, and Cerastium round has been much admired. Calceolaria, Imperial Crimson, and Christine, a good bed. Imperial Crimson and Christine contrast well.

These are a few of the best out of many. Like many of my neighbours I am quite disgusted with Gazania splendens; last year it was all right, but this year, because the weather was dry and hot when it ought to have been in its chief beauty, it would do nothing. One bed in the garden was planted with Calceolaria and Crystal Palace Scarlet, plant for plant; it was a raised bed of considerable size, it was rightfully gay all the summer, and rather kept up the impression that there was a perpetual recruiting party in the garden—its aspect was intensely military. Of all the Scarlets, Brilliant has kept up the most continuous bloom. It is, indeed, a friend in need; under glass, out of doors, in pots, or in soil, it always does what you want it. If some *serena* in the gardening world would give us a list, not too long, of bedding Geraniums of distinct colour, it would be useful to those who, like myself, mean to adhere almost entirely to this tribe for bedding purposes. All plants intended to make a good summer show—that is, in June and July, should be struck in autumn. I have just potted two thousand good plants, as good as gardeners' stock often is in May. They were all put in between July 23rd and August 10th.—R. B., *Rodcliffe-on-Trent*.

LIFTING THE ROOTS OF VINES.

As the time of lifting and replanting Vines is at hand, I wish to trouble you with particulars of the Vines intended to be lifted, and solicit your opinion on the way I purpose planting them. First, a lean-to house, with an inside front border 4 feet wide, in which are planted Vines some seven or eight years old; they are strong and healthy, but shy bearers and much troubled with shanking. On the outside border are planted Vines, some thirty years old, in a very poor state. I purpose to throw those out altogether and make a new border. As the present border is 5 feet in depth, I intend to turn all out to that depth and thoroughly drain it, then to fill in 2 feet roughish stones, on the top of which I will place 1 foot of lime riddlings, chiefly small limestones. Now, this I am most desirous to ascertain, Whether there is any fear of the roots descending through the drainage in any reasonable time, provided the compost is all that can be

wished for. The inside Vines I intend leaving as they are, to make sure of a few Grapes. They have the liberty of the outside border; but I will endeavour to leave them undisturbed as much as possible at present, and plant young Vines outside, so that, if the inside Vines do not become more productive, I can lift them when the outside ones are furnished—say three years hence.—*ALBION*.

[Your plan seems the best that can be adopted under the circumstances; but we think excavating the border to the depth of 5 feet unnecessary. We are advocates for a wide border rather than a deep one, and if the border was raised a little above the adjoining ground so much the better. If your ground is at all wet with a clayey bottom, let the foundation of the border, and along each lay a pipe-drain sunk a little below the bottom of the ridge just mentioned, and these drains to communicate with a main one to carry the water clean away. Now, supposing the top of the ridge here mentioned was only 2 feet 6 inches below the surface, and the ground to the furrow to descend 6 inches, which would be 3 feet. This will be ample both for drainage and border. Let the clay border be smoothed fine; or if you like to concrete or asphalt it, or cover it with blue slates, you can do so. The latter bedded in mortar will be cheapest; whichever it is let the drip enter the drain, and on the top of it lay a covering of bricks that have mortar adhering to them, or stones will do, and a little finer stuff nearer the top. We seldom make our Vine-borders more than 18 inches or 20 inches deep of compost, and this also contains a great deal of stones or mortar rubbish. We do not think it advisable to debar the roots from rambling amongst the drainage here mentioned, as they seemingly enjoy that more than many fine mixtures prepared for them. The only thing is, not to have that drainage too far from the surface; but if there be a foot of it and 18 inches of a suitable compost not too rich in manure, we have no doubt but you will have excellent cines at the end of two years. But give the border width. If there be a walk in the way make it border also, as we have found Vine roots thirty feet from the house. Possibly we may be giving some more particulars on this important subject, which is one of the utmost consequence to the fruit gardener and all the community as well.]

NEW POTATOES IN THE OPEN GROUND
BY THE 1ST OF MAY.

I HAVE just read my notice and the reply of "W." about planting early Potatoes. "A place in England where there is scarcely any frost!" Well, thought I, I have committed myself; but to make as good a job of it as I possibly could I went at once to my neighbour, and the facts are these.

He has grown early Potatoes in the spot mentioned for eight or ten years, mostly planting in the latter part of November, and has never had a crop injured by frost, except that once or twice his Potatoes were up forming rows, when a very severe frost rendered the land around almost as impervious as iron, and the pools would bear the weight of man or beast, but the plants came up in a short time just a little yellow at the top, but not injured a bit. Many times when it has been rather tough work to break the frost on the pools with the heel of your shoe, this Potato-ground was not frozen in the slightest degree; and for hoar frost it is just a thing to laugh at, for it has never injured a leaf. Without a single exception the hoar frost has been as harmless as the "dew at summer eve."

With respect to "W.'s" remark—"Your St. Ives correspondent must not expect to rival his neighbours in the vicinity of Penzance," my friend says, "I challenge any man in the kingdom to raise Potatoes in the open ground sooner than I." He has sometimes taken his crop on the 1st of May, which yielded about one-third of a Cornish bushel per acre of 36 square yards, one-third of a Cornish bushel being about 75 lbs.

Mark, my friend is not a gardener, but a farmer, and a farmer of the old school. The fact that those plots, now so valuable for early Potato culture, were not cultivated at all for many years until a "sharp one" in the neighbourhood asked for them, shows plainly enough that my old friend is no adept in the culture of early Potatoes. Indeed I know that though he has his crop early in May, and the seed not sprouted—his seed has not been of the earliest kind; he calls them "Asbridge Kidneys" (Ash-leaved Kidneys?)—and the probability is that if he planted

the earliest kinds he would have his crops much earlier than the 1st of May.

P.S.—I have just been seeing the little plots of ground. It is situated on the western side of St. Ives bay, with an aspect a point or two south of east, the irregularities of the ground giving them that advantage. Sheltered on every side, except a little exposed to the east and south-east winds, but not much. My friend has never had the plants blasted by the wind of any consequence but once, when the east wind blew with great force. The soil, I suppose, may be called loamy (I do not understand much about the names and nature of soils). It rests on a stony clay, and is very deep; and under the clay is the "trap" rock. An inclination of at least 15° gives it the advantage of good drainage. The sea is near enough for one standing in the meadow or garden to throw stones to the gulls, and hit them if he can throw "nice" enough—in fact, a few yards at most; and the bottom of the plot, the lower part I mean, is only a few yards above the sea level. The manure applied to the crops is of no particular kind—guano, sandy dung from the house, &c. It has the first peep of the rising sun, and to-day the subbeams were still smiding on it at three o'clock; but I think they were on the point of leaving. I forgot to ask him about the earthing up, but will try to remember next time I see him. He has taken up his crop on the 1st of May in the open ground, and sold for £4 per Cornish bushel, and made of a small part of the plot at the rate of £250 per acre at home; but of course he did not make that of the whole.

I suppose the rocks below must favour him by the sun's rays striking there and glancing on the land; for they run out at a gentle inclination for a good way.—M. ANTHONY, *Providence Mines, St. Ives, Cornwall.*

PROPAGATING CERASTIUM TOMENTOSUM AND LOBELIA SPECIOSA.

Will you inform me whether *Cerastium tomentosum*, which I use as an edging, should be reared from cuttings, or if the plants are left in the ground will they remain alive through the winter, and make a good edging for next season? Also, whether *Lobelia speciosa* should be reared from cuttings taken now, or from seed; or would a few old plants saved through the winter furnish cuttings in the spring?—B. B.

[These inquiries have been answered repeatedly. The *Cerastium tomentosum* is quite hardy, and is to be divided at the roots every year in April and replanted, and it comes from cuttings to begin with easier than any other plant. Old plants of *Lobelia speciosa* should be kept over the winter, and cuttings made from them in the spring; but it comes quite true from seeds. Some of the first houses in London, however, did not send it out true the last two seasons; but you can get it guaranteed, or a certain sum of money if it is not true. We would not advise any one to buy *Lobelia speciosa* seeds. There were thirty kinds of *Lobelia speciosa* sent for trial at Chiswick in 1860, and, of course, only one of them was true. The seed trade in general do not know it at all, and every one must save his own seed of it till the true kind gets into the regular market. The Royal Horticultural Society grow their own seeds of *Lobelia speciosa*; at the Crystal Palace they do the same; and at most of the large country seats the same also, and it never varies in the smallest degree with all these parties. Nevertheless, we ourselves failed to procure it in London no later than last season. We recommend the subject to the attention of dealers.]

PRUNING ROSES IN POTS.

Mary is trying to grow a few Roses in pots. They are all China and Tea-scented ones, on their own roots, most probably from cuttings struck early this year; at all events, with the exception of one—*Deveniensis*, which is two years old, they are not more than twelve months old. *Mary* has read carefully Mr. Appleby's directions for the culture of Roses in pots, but she is afraid she does not quite understand the term used in reference to pruning China and Tea Roses. He says (Vol. XXIV., No. 14, July 31st, 1860, page 212), the method of pruning them may be designated pollard pruning, or cutting the shoots close to the soil of the pot. Does he mean all the shoots are to be so treated? and are old as well as young plants

to be pruned so closely? *Mary* intends to put her Roses in larger pots. Will it be better to prune them in November, or to wait until the spring? They will be in a cold frame during the winter, and be placed in a small conservatory in the spring. *Mary* would not have troubled the Editors with these questions, but the gardener of whom the trees were bought told her the less Rose trees growing in pots were pruned the better for them, and to take the point of the shoots out was quite sufficient for them. The names of the Roses *Mary* has at present, are Adam Moiré, Archduke Charles, Queen of Bourbons, Souvenir d'un Ami, and *Deveniensis*. This last has three stems, and is in an eight-inch pot. The others are in five-inch pots. Most of them have had flowers on, but they are not in a good shape, and *Mary* would like to try to grow them into a better shape.

[The gardener who told "MARY" that the less Rose trees growing in pots were pruned the better for them, and to take out the points of the shoots was quite sufficient for them, cannot have had much experience of the culture of Roses in pots, nor can he ever have seen the Roses in pots exhibited by the great Rose growers at the shows near London. The particular class of Roses "MARY" alludes to—namely, Tea and China, require close pruning, because they bear their fragrant flowers on the current year's wood, and, therefore, when they are pruned they are something like pollards, a term Mr. Appleby uses to distinguish that mode from the more open system that stronger-growing classes of Roses require in pruning. The reason why Tea-scented and China Roses are better for pruning close is, because the young wood of these kinds is more tender, and does not ripen much beyond the lowest parts of the year's shoots. If "MARY's" plants are weak and have but few shoots she should cut them down close, and in the spring when fresh shoots appear and have made some length of shoot, they should be spread out equally on every side, so as to form handsome specimens. The best compost for Tea and China Roses is a mixture of loam—that is, decayed sods one half, and old cowdung, leaf mould, and silver sand in equal parts to form the other half. Repeat now and place the Roses against a shady wall on coal ashes. Towards the end of October remove them into the cold pit, keeping the soil just moist and no more. Then when the leaves turn yellow and partly fall off, prune the plants down to near the soil, and let them remain at rest till February or March. Then give them a soaking of milkwarm water and remove them into the conservatory. Attend to the training as the shoots advance, and keep down insects, and with regular watering, syringing, and keeping up a moderate temperature "MARY's" Roses will give her satisfaction. Repeat the potting and pruning in the following autumn, and then the plants will continue to advance in size and beauty year after year.]

EDGING MATERIALS FOR WALKS AND BEDS.

I HAVE read with interest Mr. Robson's communication on the above, and having tried various things allow me to say that, like many other discoveries, I accidentally found some bricks with round top-sides which I found to answer very well by putting a row of common brick for a foundation under them thus:—

They have stood the test of seven years, and are as good now as then. I then got the maker to lengthen both the depth and length of the bricks, in order that I might dispense with the bricks below, and have now had them in use five years—18 inches long, 9 inches deep, 3 inches thick, and round on the top, made of fire-clay, and cost 6d. each. The great secret is to take care not to cut or break in any way the

outer crust, for if done the weather speedily gets in. I consider them superior to all other kinds of bordering, and I fancy that many plants, the *Asarum*, *Gentianella*, *Saxifrage*, *Veronica*, *Campanula*, *Sedums*, and other dwarf edging plants, show a decided preference for the brick edgings to grow upon or against. There is no difficulty in having them made angular or curved for corners and bends.—W. X. W.

COLOUR AND CONTRAST.

A BOUQUET CRITICISED.

"R. E." is much obliged for the information contained in THE JOURNAL OF HORTICULTURE, of the 17th, relative to the law of colour and contrast; but at the same time acknowledges himself to be still rather perplexed in the matter. If scarlet is inadmissible with purple, what would Mr. Nesfield say about the oblong beds in the Horticultural Gardens, South Kensington, which branch out in long succession on either side the centre walk, which leads to the large circle in front of the conservatory? "R. E." is willing to admit it may not be according to rule, but there are few rules that have not some exceptions; and if we look at the extreme richness of colour in the beds before mentioned, and which in the perspective form a long mass of scarlet and purple, it must, he thinks, be allowed that the rule which prohibits such an arrangement must be rather precise and unwise. It is true a bed of flowers should not be taken as a model for a bouquet; but it is difficult to understand that if the combination is right in one it should be wrong in the other. With regard to the foliage of the Flower of the Day Geranium in the beds alluded to at Kew, altering the case in any way is also difficult to understand, as the bouquet in question was surrounded with foliage of that Geranium, and giving much the same effect as the beds do. But it is not only in the foliage that the effect is so rich, which is only seen when standing near the beds; but taking about fifty paces away, when the tops of the bloom of the Geranium are seen surrounded by the violet of the Purple King Verbena, the contrast is truly beautiful. It is certainly more correct, perhaps, to mix or place in juxtaposition purple and primrose, or purple and white; and, perhaps, it ought to have been mentioned that one of the eight bouquets which were used in the floral design was of violet Aster, edged with *Calceolaria amplexicaulis*; the whole of the bouquets being laid on a circular bed of *Lycopodium denticulatum* more than a yard in diameter, the bright green of which formed a nice groundwork for the flowers. Purple or violet undoubtedly consists of a mixture of red and blue, but when the blue so much predominates as it does in violet, is it a great mistake to place vermilion or scarlet near it? much less a yellow shade of vermilion, which is the shade of the Flower of the Day Geranium. If the colours are separated which compose violet they will be found to be carmine and blue, the former colour having little or no affinity to vermilion. This is a fact, probably, not always considered: hence the confusion caused by the two colours being classed as red. But "R. E." would be greatly obliged to the Editors of THE JOURNAL OF HORTICULTURE, or any other learned contributor for a little further information on the subject if they would kindly favour him.

[I do not think I could have undertaken to reply to "R. E.'s" question a few days ago, had it been understood to involve any reference to the practice of laying out flower-beds—a practice subject to innumerable modifications and exceptions universally acknowledged to be perfect in its arrangement in the instances "R. E." means, and an arrangement of which the writer cannot speak from experience, never having been able to see those beautiful plans in the gardens mentioned.

"R. E.'s" question referred expressly to "the rule" of colour, and to a bouquet arrangement of "violet and cerise." Thinking, of course, that it was a strict question of rule, the writer replied by stating that rule certainly to exclude the juxtaposition of the colours named, in which colours every flower painter knows the addition to the cerise of a good deal more blue, and to the blue of a good deal more carmine, would render the cerise violet and the violet cerise. I do not mean to say that they would certainly hit the exact shades of the flowers used, but to all intents and purposes for mixing the flowers they would be the same.

"Purple and scarlet," of which "R. E." now speaks broadly, while he also asks if the rule has "no exceptions," may be in two ways admissible. A cold purple approaching to dark blue in its general effect and a yellowish-scarlet would be a striking contrast. But no colour that I can think of is more free from the slightest tinge of blue than is that same scarlet, which cannot be said of cerise to the same extent.

Purple or even dark violet and scarlet have again in their use as many exceptions as possible to fall back upon. A regular design of scarlet on a purple ground can be readily conceived to look very striking. Probably in the garden arrangements, which must be so beautiful, the impression is that the purple only

enfames the more brilliant colour, and thus it may be considered more as an accessory than as the colour of the design.

It strikes me in confirmation of this idea, that in speaking of these designs it is always the bright flower which is mentioned first, the other only as its accessory. Not Flower of the Day, and Purple King, but Flower of the Day edged by Purple King. After all it is possible that "R. E." and myself are writing at cross purposes regarding the use of the terms violet and cerise, purple and scarlet. I define violet as a very warm—i.e., red shade of purple, and cerise as scarlet, one stage advanced towards crimson.

The expression "pale yellow, white, or green, are the only good contrasts to a purple flower," refers to those cases, as in the bouquet described by "R. E.," in which the purple and the other flowers are equally the colours; not where one is made the mere foil of the other; and the terms purple and red were used in the former reply merely in the idea of including the violet and cerise, supposing there to be a difference in the definition of those colours, while cerise and violet would not have so well embraced the reds and purples generally.

One more point must be mentioned. Is not the effect extremely different of a bright colour framed in a mass of a darker tone and done with, or a dark flower surrounded with bright ones, and then edged with a third colour also very light?

I have given some thought to the subject since receiving "R. E.'s" first letter, and though I do not happen to have the flowers at hand to try, it strikes me that as far as the colours were concerned, a reversal of the design—cerise, or rather pale scarlet centre, variegated band, and purple edge, would have produced more nearly the colour effect of the beds at Kew, and been at the same time correct as to the usual rules of colour. This would not, however, of course, have been a good bouquet. It is very seldom that the same designs can succeed for two such different purposes.

If blue did very greatly preponderate in the violet of Purple King Verbena, the scarlet certainly would be more in place. But is it possible that in violet, blue can be said to have more than a slight share in the tint at all?

The other bouquet being correct as to colour, no doubt added greatly to the bad effect of that under discussion.—E. A. M.]

PILLAR ROSES FOR NORTH WALES.

MANDEVILLA SUAVEOLENS AN OUT-DOOR PLANT.

Will you give me the names of a few climbing and pillar Roses suitable for north Wales, the situation about four miles from the sea, sheltered, and generally mild? The profing being that Myrtles, Sweet Verbena, and many other greenhouse plants live out all the year round, though the last severe winter has killed many of them to the roots. I cannot help mentioning that the *Mandevilla suaveolens*, which was trained against the house three years back, has never been the least affected by the seasons; it now reaches to the windows of the second story, and has been in very fine bloom best part of the summer, but I do not observe that it will seed this season which it did the autumn of 1859.—H. A. D.

[The first climbing Rose for that mild climate, the very first where we have heard of in Britain, where *Mandevilla* lives out the year round, is *Isabella Gray*, on a south wall, and not to be touched with a knife for the first seven years. You must get one on its own roots. The rest are true and proved. *Gloire de Dijon*, finest buff yellow. *Triomphe de Rennes*, splendid canary yellow. *Celine Forestier*, a flat, pale, yellow flower. *Lamarque*, all but pure white. Cloth of Gold and *Solfaterre*, same treatment as *Isabella Gray*. *Fellenberg* and *Jaune Desprez*, very strong. All *Noisettes* for climbers except *Gloire de Dijon*, a Tea. The following only for pillars:—*Hybrid Perpetuals*.—*Alexandrine Bachmetoff*, *Anna Alexief*, *Auguste Mié*, *Baronne Prevost*, *Caroline de Sansal*, *Duchess of Norfolk*, *Général Jacqueminot*, *General Simpson*, *Jules Margottin*, *Lord Raglan*, *Lereson Gower* or *Souvenir de Leveson Gower*, *Mathurin Regnier*, *Mrs. Standish*, and *Oriflamme de St. Louis*. *Bourbons*.—*Louis Odier*, *Pierre de St. Cyr*, *Sir Joseph Paxton*, and the *Malmaison* or *Souvenir de la Malmaison*.]

CENTAUREA CANDISSIMA.—I cannot understand the difficulty of propagating *Centaurea candissima*. I bought one two years or more since, and in the summer of 1860 turned it out, when it

made numbers of side shoots; these I took off and placed under a hand-glass, removing it every night—only two missed. This year, as I wanted a few to give away, and was about leaving home for a time, I earthed up round the stem of one with fine sandy earth, first slightly putting outwards all side shoots; they rooted freely.—H. B.

COMMON PLANTS WITH REMARKABLE FOLIAGE.

(Continued from page 380)

SAXIFRAGA HYPNIFORMIS, or **S. TRIDACTYLITES** (Moss or Stag-horn-leaved Saxifrage).—This beautiful moss-like plant is certainly not so much cultivated as it deserves, as I am not acquainted with any plant of the Lycopodium or Selaginella family that looks half so lovely. Close and compact in growth, and of the most immitable green, which the severest winter scarcely affects, the frost of last season which browned and discoloured all the wild Mosses or Hypnuses had no impression on this hardy alpine; and from the middle of July to the end of April it presents a close, compact mass of the densest emerald green, the little cushion-like tufts of thick-set stems resting on each other, with their terminal points all turned upwards. It grows best in rather moist, shady places. Shade, however, is more necessary than moisture, and if planted between stones it speedily overtops them, forming tufts or cushions of the richest possible green, and as an adjunct to the fernery it is indispensable. Neither do I regard it second to any Fern for beauty and interest; its thickly clothed foliage, moulded into something very like a stag-horn shape, will bear inspection with the fronds of any of the larger Ferns, and certainly is more handsome than those of the Hymenophyllum and smaller sorts. It is also easy of culture, spreading over the ground in a compact and not rampant manner. It grows to it as it advances, and these self-layers become excellent plants, growing at any time of year if supplied with shade and moisture to begin with. It, however, dislikes full exposure to the sun, though it will bear an eastern or western aspect, but on a bank facing the south it does not look so well. I had an instance of this the present season. In forming a rustic ornamental bed for bedding plants on the lawn, which was slightly raised and surrounded with rough stones, this Saxifrage was planted as an edging amongst these stones some time in April last, and during the showery weather of the early part of summer grew freely, more especially on the north side; and when dry weather set in the beginning of August, the plants on the south side ceased growing, while those on the north side, though receiving no further shade than occupying the northern slope, continued to grow, and have looked all that could be desired, only the tips of the stones being visible, and these it is not intended to cover. On the south side, though the plants look green, they are much smaller, but may with the autumn rain make up much of their lost position. I am not acquainted with any plant so well adapted for ornamental rockwork as this. The only time in which it is not ornamental—and all plants have this period in their annual duties, and some that are much esteemed have quite eleven months out of the twelve that are so—is the time the plant is forming fresh shoots after flowering, which is from the middle of May to the same time in July, not more than two months, and during that period the flower is far from being uninteresting. A white blossom on a stem 6 inches to 8 inches high, the plant at the time making a sort of wiry growth, is not so pretty; but, as above stated, it is not long in resuming its deep rich green hue, which it retains all the rest of the year, unless it be usually exposed to an extraordinary glare of long-continued sunshine, when it suffers a little, but as we possess plants better adapted for such sunny quarters this one need not be so exposed. Some of the Sedums like a sunny spot, and many alpine plants will endure that also; but as plants with remarkable foliage were the subject under notice, we must keep to that matter.

THE GLOBE ARTICHOKE.—It would be difficult to take a wider step in the range of vegetable matters than one from the neat but humble Saxifrage to the aspiring Artichoke, and in colour they are almost as widely different as if neither of them had any claim to one original hue (green). Their purposes are, however, widely different. The Saxifrage may be planted close under the eye, and is better of being so. The Artichoke ought to be some distance from the spectator, its foliage being larger, and having

a sort of exotic aspect looks best at the distance of a quarter of a mile or so, and for giving effect to a shrubbery at the distance here mentioned it is useful. A few plants standing in front of a mass of some common evergreens give it quite an oriental aspect, the foliage being more necessary that way than the flower-heads, although these, as vegetable productions, are singular and interesting. The Globe Artichoke likes a deep, rich, garden soil with a well-drained bottom; and though it is about as hardy as most plants, yet it is sometimes killed by very severe winters, if not protected, which it is easy to do by sticking a little fern or laying some litter around the collar, covering up some of the central shoots, and allowing the outside ones to fall over to act as an additional protection. But as its appearance in winter is not so good as in summer, it ought only to be planted in situations where its summer services are wanted—on the opposite side of a piece of water or inaccessible object, and clothed with evergreens behind it, which look well at all seasons, but are quite cast into the shade by the graceful foliage of the Globe Artichoke waving in the breeze, and every undulation disclosing the silvery whiteness of the under side of its foliage, conveying a tolerably good idea of tropical vegetation, though in itself it may be one of the most common and neglected of plants.—J. ROBINSON.

(To be continued.)

MR. BENNETT'S VINES IN POTS AT WORKSOP.

YOUR correspondent Mr. Bennett is determined to be both judge and jury. The coolness of his letter in your Journal of last week must be most amusing to those who had the opportunity of seeing his Vines, and thus practically knowing the serious discrepancy between the implied meaning of his words and that told by the roots of the Vines.

Probably, the best way of giving you a fair knowledge of the case will be to state the exact measurement of one of the roots—viz., 3 feet 3 inches, banging from the top of the outside pot; add to this the length from the crockhole of the inside pot to the top of the outside one, which we may fairly state at 18 inches, and we have 4 feet 9 inches. It is to be regretted now that the Vines were not lifted clean out of the outside pot, so as to show the full extent of the roots outside, for the roots may have been much longer than I have mentioned. The insertion of the Judge's hand once brought away four roots.

The crockhole of the outside pot was fastened up with a cork and the space between the pots filled up with roots and water, and the top carefully covered over with moss, so as to hide the inner pot.

One of the rules of the Society printed in the schedule says, that "the decision of the Judges shall be final." Mr. Bennett places himself in a false position when he proposes himself as the judge of the Judges.

Mr. Bennett was present last spring when the rules and the schedule passed the Committee, and he drew numerous very fine distinctions as to the meaning of many phrases; but he entirely forgot to inform his brother Committeemen as to his meaning of Vines in pots.

Why did Mr. Bennett refuse to have a fair statement of the case placed before a competent authority and then send his own *ex parte* statement to him with every question answered by himself?

Every first-class gardener in the district, and there were many of them present at the Show, gave a very decisive and undoubting answer against Mr. Bennett.

Will Mr. Bennett be kind enough to state, for the information of other gardeners, how he is able to keep his so-called tap-root (by which I suppose he means the leading root) within the pot, whilst all the other roots find their way out? and, as he himself strongly objects to the roots going over the top of the pot, is it because his tap-root would go over the top in preference to through the bottom?—J. T. & G.

HAVING read Mr. Bennett's letter of the 17th inst., relating to pot Vines rooting through the crockhole at the bottom of the pots, and your reply to the same in reference to the Judges' decision, I was highly interested with your conjectures, which I thought admirable, showing well your intimate acquaintance with the subject you had in hand.

Well, in reference to the Vines having any other support than the soil contained in the pot; of that there is not the least

doubt, for the Judges having exposed the roots which the outer pot contained (where they were well supplied with moss and water), and placing them carefully over the edge of the same, they were there telling their own tale as to what service they had been to the Grapes, which were so skilfully supported above with iron and timber.

Now, just to give you an idea of the general feeling confirming the Judges' decision, thirteen practical gardeners were called together by the Committee on the ground, to give an opinion as to whether the Judges had justly disqualified Mr. Bennett's Vine or not, and their decision was unanimous (with one exception); for, seeing the fine, healthy roots hanging in profusion from 3 feet to 4 feet long, they could not do otherwise than approve of the manner in which the Judges had so conscientiously and intelligently acquitted themselves by their decision—viz., disqualifying the should-be pot Vines. I think this unfair attempt being detected met its due reward—viz., a multitude of thorns. Myself being a lover of fair play, I forward you the above true statements.—A GROWER OF POT VINES.

[The wording of the rule ought to have been more precise. A similar want of precision led to a similar occurrence with *Chrysanthemums* in pots at a Colchester Show. "For Vines grown entirely in pots" would admit of no mistake.—EDS. J. of H.]

GARDEN NOTES.

WASP-NESTS.—I think the small can of coal tar "T. R." recommends would not fill many wasp-nests. I destroy them in a much easier way: I take spirits of tar, turpentine, or paraffin oil, whichever comes handiest, pour a little into the hole, stop it with cotton or rag, pour a little on that, and the job is finished—a great improvement on the old plan of powder and sulphur squib, with all the trouble of driving them out.

TROPEOLYTES.—As Mr. Robson invites communications about *Tropeolums*, I beg to say that I have a seedling of the Stamfordian breed which has done good service as ribbon-rows. It is a good scarlet, and with a considerable amount of disleafing it is superior to scarlet *Geraniums*. It does better in a bed, as it sooner exhausts the soil, and does not go so much to leaf. The wet season we have had in the north has made it grow rather luxuriant.

DIPLONTAXIS TENUIFOLIA VARIEGATA.—Many and various are the variegated plants that are made: use of as ribbon-rows and edgings to beds, but amongst all the reports of the most celebrated places I have never seen this mentioned as being made use of. I therefore beg leave to call attention to it, as it makes a very good edging about 9 inches in height—some think equal to Golden Chain *Geranium*; and as it is very hardy, and easily propagated in spring, it is, therefore, in my opinion, worth the attention of all who have a great amount of edging to do, and also a demand for variety. The flowers are insignificant, but it is easily kept in order by cutting them off.—A. K.

SCHIZANTHUS CULTURE IN POTS.

The *Schizanthus* is undoubtedly a charming thing when grown with an ordinary amount of care for the decoration of the conservatory in the early summer months. It is one of those annuals that never fail to obtain the admiration of all, when cultivated in pots.

To do this successfully seeds should be sown at once in a gentle hotbed if one is at hand; if not, in a close cold frame. Here the seeds will soon germinate. Keep the seedlings moderately moist, but avoid damp. As soon as large enough place them singly in small pots, and encourage them to grow as much as the season and state of the weather will permit till the end of November, when they may be removed to the cool greenhouse.

Here they will require some little attention, as they are at this season liable to suffer from damp. Water sufficiently to keep them from flagging is all they require from the time of their admission to the greenhouse till the end of February, at which time they will show appearances of growing. Then is the time to give them a shift—say from a sixty to a forty-eight-sized pot, using compost thoroughly pulverised, but which should be both light and rich.

After shifting, the plants would be benefited if they could be placed in a higher temperature till they can form fresh roots in

the new soil, but not longer; for if allowed to remain in such a growing state they would soon get weak. A steady, robust growth is more to be desired than the flimsy, long-jointed growth which must follow from the excitement of a higher temperature.

Having brought them back to the greenhouse, the best treatment to give them is precisely the same as you give your *Pelargoniums*. Two more shifts will make them fit objects of adornment for any conservatory as a single or specimen plant. For general purposes at this season they will be found to be highly valuable also, affording a very agreeable change both in colour and character.

In conclusion I must add, these remarks are only applicable to the taller-growing kinds, as the others are not so well adapted for pot culture. The varieties I grow are, Hookeri, pinnatus, and pinnatus Preslii.—J. C. CLARKE, Wakehurst Place.

POMOLOGICAL GLEANINGS.

STRAWBERRIES.—Is the well-advertised Strawberry General Havelock the same as the old French sort *Crenont* at one time advertised as a "perpetual Strawberry" by a Bath grower? I observe that Mr. Nicholson queries this in his catalogue. Is *Rival Queen* the same as *Omar Pacha* and *Myatt's Eliza*, as stated by the author of the "Fruit Manual," and by all the growers? The question is, Who is the person that renames these things? If done for the purposes of trade he should be inquired for and exposed.—HAUTOBOS.

SEEDLING STRAWBERRIES.—I have a plot of ground about 20 feet square devoted to a batch of seedling Strawberries raised from seed in 1859. This year every plant bore fruit, and a most interesting employment it was during last July to look at and taste the numerous varieties, for no two were alike; and amongst some hundreds of plants scarcely a very inferior kind could be found. They were raised from two or three good varieties, hybridised with the hope of procuring something very early or very late; for we have enough mid-season varieties and plenty to spare. I believe that I could have found among my seedlings at least one hundred varieties which, well described, would have formed a very respectable catalogue. The wonderful, the unlimited variations that Nature, assisted by man, gives is to me more mysterious—more beyond our "ken" than ever. Allow me to illustrate this proposition. Take one large ripe fruit of a British Queen Strawberry, squeeze it quite flat so that its pulp will spread over a surface equal to a breakfast-cup. Place the pulp thus spread out on the surface of some mould in a flower-pot; take some fine mould, and sprinkle over it till it is covered to about one-eighth of an inch thick; cover the pot with a piece of wire, so as to admit moisture but keep the seed from injury by mice or birds. The following spring, about the month of April, your young Strawberry plants will make their appearance. You will probably raise from your single large Strawberry a hundred plants. The most marvellous thing is that not one of these young plants will be like its parent the British Queen, and no two exactly alike.—T. R.

PINE APPLE CULTURE.

The Pine Apple has been denominated the "King of Fruits," and I think justly so, whether we consider its qualities in reference to its wholesomeness, its agreeable rich flavour, or its size: in all these qualities it is equal to, and in some superior to any other known fruit. In regard to its being good for food, the only drawback I ever heard of was, that, eaten in large quantities, it was astringent—a quality in hot climates rather of advantage than otherwise. In rich, aromatic, agreeable juice I know no fruit that is equal to it. I remember some twenty-five years ago, when I had the charge of the extensive range of pinceries at Hoorforth Hall, in Yorkshire, exhibiting some large Providence Pines at an exhibition at Leeds. The Rev. James Arncliffe Rhodes, my employer, was chairman; and on my being called up to receive the head prize for Pines (that was the fashion there then), he ordered me to cut them into slices and distribute them amongst the company. In cutting them I found the juice so abundant as to fill the large dish with it: this juice was of a rich amber colour, and very aromatic and refreshing to the palate; no Melons, Peaches, Apricots, &c., would have yielded so much juice. The last quality size in the Pine Apple is A1, no other eatable fruit approaching it. I have grown it from 8 lbs.

to 10 lbs. weight. My old friend, Mr. Mills, grew one in a pit at Gunnersbury 15 lbs. weight; and there is this advantage—that the larger the kind is grown the higher flavoured it will be. I do not know to what weight they are grown in their native country; but if we may judge by the specimens imported from the West Indies, we grow them much larger in our hothouses than they are ever seen in tropical countries. It is very likely, however, that the gardeners there pay but little attention to the culture of the Pine Apple to obtain heavy fruit; in that quality our best gardeners have, within ten or fifteen years, greatly improved. It is no unusual thing now to find Queen Pines fully 7 lbs. or even 8 lbs. weight.

In other points the culture of the Pine Apple has improved much since the days when I was a lad in gardens, and that is the fruiting them in less time. Loudon describes the Pine as a triennial plant—that is, producing fruit when three years old; but since he published that we manage to fruit our Pines in half that time. It is a fact that I have known Antigua Pines grown for six years and never fruited. Any good Pine grower now would think that fact incredible. The reason why Pines do not fruit I will give hereafter. Another modern improvement is in the size of the pineries; generally they are not so large nor so

lofty as formerly. Reflecting upon these points and some others I have taken up my pen with the intention of writing down my experience in Pine Apple culture, and embodying with it every point of modern culture worthy of imitation. As there is nothing like order, I intend to divide my subject into—1st, the best kind of houses for Pine culture; 2nd, list of the most esteemed varieties; 3rd, the best kind of soil; 4th, watering, which includes syringing and atmospheric moisture; then 5th, summer culture; 6th, winter culture; 7th, propagation, including by crowns, by suckers, and by seeds; and lastly, insects that feed on this plant, and the modes of destroying them. Many of these sections will be subdivided so as to be more intelligible.

I conclude these preliminary remarks by observing, that I write this essay on Pine culture, supposing that my readers are desirous of full and minute directions on every point of culture. In a great measure my instructions will be superfluous to such of my brethren as are well acquainted with, and in full practice of, the best modes of cultivating this noble fruit. To the beginner and young gardener I do hope my observations and instructions may be of some service. If any such growers are benefited by my remarks I shall not think my labour in vain.

HOUSES FOR PINES, USUALLY TERMED PINERIES.—To cultivate the Pine Apple to the highest perfection, three houses are advisable. One for the youngest plants—viz., crowns and suckers; another to grow the plants a stage further till they are fit to fruit; and lastly, the fruiting-house. Unless a large number of young Pine plants are wanted for sale or exchange, the first house need not be above half the size of the other two. Many good growers place their suckers and crowns in a pit or a deep large frame, the heat for which is obtained and kept up by linings of dung. For small places such a mode may be of service; but where expense at first in erecting the best houses for Pine Apples is not a consideration, I recommend good brick erections for all stages, with walls all round, in order that every plant may be constantly in sight in all weathers and seasons. It is obvious that when so arranged greater facility is given for every operation—such as watering, steaming, removing for repotting, and so forth. For convenience, I am decidedly of opinion that the pineries should be all in one range with glass divisions and widish doors, so that the plants when large enough may be moved from one house to another without breaking the leaves. A large and commodious warm shed behind is indispensable for the purpose of repotting the plants, and to be spacious enough to hold all the plants of at least one of the houses, whilst the renewal of the pit in which they are to be plunged or planted out is effected. As the pits inside the houses are of similar form, whether the plunging or planting-out system is adopted, I need not in this place consider which of the two plans is the best. The form of the house is of some consequence. From all that I have observed on this point, I have come to the conclusion that what is called lean-to houses are the best for the growth of the Pine Apple. The advantages of this method above span-roofed houses are—1st, Economy of fuel. It is evident that a solid brick

wall on the north side of a lean-to house will keep more heat in than a glass wall, and, consequently, there will be less heating power required to keep up the internal atmosphere to its proper height. 2nd, The roof of a lean-to house may be at a lower angle, and, consequently, the pit may be nearly level, the plants will then be all at an equal distance from the glass. 3rd, The plants in such a house occupy the best position for growth. In a span-roof the walk generally is in the centre on account of head-room: hence the best space for plants is wasted. Whereas in a lean-to the back walk may be slated, and then all the glazed part will be occupied by the plants. Lastly, When the plants require potting they are easily carried into the warm shed behind a lean-to house; whereas in a span-roof they must necessarily be exposed to the external cold whilst being carried to the potting-shed.

SIZE OF THE HOUSES.—To produce about one hundred fruits annually, I have calculated that the houses should be respectively—fruiting-house, 60 feet; succession-house, 46 feet; and nursing-house, 30 feet. The width of them all to be equal—that is, 14 feet. That will give 8 feet in width to the pits, and 3 feet each to the paths, which should run all round. Each house to be separated by a glass partition and glass doors. The nursing-house pit will necessarily be shortened in length by the cross wall: hence I set it down as 26 feet in length. As the plants will be small at this stage, 1 foot apart in the row and five rows longitudinally will give ample space for 130 plants. It is better to have a few too many for fear of accidents or failures. In the succession-house there will be no cross walk: hence we have the whole space occupied by the pit 46 feet long; and as the plants will, when brought into it, be much larger, I plunge them at 1½ foot apart, and put them in four rows, which give the number to fill it 124. In this pit they remain till they

are fit for the fruiting-house; and as I expect they will then be large and in large pots, and the pit is 56 feet in length, being shortened about 4 feet by the end cross-walk and end wall in this their last home, I allow them fully 2 feet in the row from plant to plant, which gives me twenty-eight in a row, and four rows, of course, gives 112 fruiting plants, and if all goes on well will produce that number of fruits.

Ground Plan and Section of a Fruiting Pine Stove, 60 feet long and 14 feet wide, heated by hot-water pipes.

Some of my readers may think that number not sufficient for a range of houses 45 yards long, but if the number is less the weight will be more. Nothing is gained by growing Pine Apple plants too thick. There ought always to be sufficient space for the leaves to have full exposure to the light. They are then stout and broad and able to bear their own weight when moved; whereas, when grown very thick the leaves are long, thin, and weak, or, in other words, they are what is called drawn—something like seedling Cabbages when allowed to stand too long in the seed-bed. Every grower of that useful esculent knows that if his Cabbages are not planted out at least half a yard apart the heads will be small and almost worthless. So it is with Pine plants grown too thick in the pits, whether in a nursing, succession, or fruiting stage.

HEATING.—On this point I believe all growers of the Pine Apple agree that there is no mode equal to that of a well-arranged system of hot-water pipes, either alone or in conjunction with smoke-flues. I think it is a pity to allow all the heat from the fire under the boiler to waste its power in the open air out of the chimney top. My plan is to have hot-water pipes in sufficient quantity running across one end, on the front, across the other end, and returning the same way to the boiler. The smoke from the fire I conduct in a flue in the back wall, returning back once, and then again to the chimney. By the time it reaches the chimney the heat will be pretty nearly given out. By heating this wall it not only warms the house in part, but also the potting-shed behind.

There are various kinds of boilers for heating the water to circulate in the pipes. Tubular boilers, multitubular boilers, cannon boilers, and what not; but of all the shapes and forms give me a good saddle boiler. It is the cheapest and best, simple in form, and easily set and heated, holding enough fuel to last through the longest night. The pipes containing the water should be neither more nor less than 4 inches diameter, and there should be four in number, two ascending, and two descending, and as the seasons vary the pipes could be used accordingly—that is, one pair might work in mild weather, and the whole four in severe frost. This might be easily managed by having a stop-cock to one or both of the pairs of pipes.

HEATING THE PITS FOR BOTTOM HEAT.—The common method is to fill the pits with spent tanner's bark, and when judiciously managed no better material can be found; but when

tan is used it should never be thrown into the pits direct from the tanyard, especially if fresh taken out of the tanner's pits. It should be earthed home and laid in a heap either under a shed, or, if in the open air, covered with something that will turn rain off it. In this state it should remain till all the superfluous water has run from it, and a fermentation has commenced, then it is ready to be placed in the pit inside the house, and then allowed to become warm before the plants are plunged in it. This refers, of course, to the pits of a new range of houses being filled for the first time. Afterwards the best of the old bark may be preserved and put up on the top of the new whenever the heat requires to be renewed.—T. APPELBY.

(To be continued.)

THE OSAGE ORANGE.

THE only method of bringing this tree into a bearing state would be to place it in a 13-inch pot in an orchard-house, not allowing it to root through, but starting it into fruitfulness, always remembering that the fruit, although like an Orange, like the Apple of Sodom, is dry and utterly uneatable. It does not come from South America, as stated by your correspondent, page 496, but from North America. It is perfectly hardy. I have a hedge 170 yards long growing in a sandy soil. This was planted in the spring of 1858, and was killed down to within a foot of the ground last winter owing to the shoots being quite unripe. In the winter of 1859 not a shoot was touched, they were ripened by the preceding warm summer.—T. R.

THE ONLY KNOWN USE OF CRINOLINE.

THE fruit trees in my orchard-house have been much blighted this year, the tops of the young shoots curl up. I have, I think, destroyed the fly now. Not being able to smoke the house in the ordinary way, I have used a lady's crinoline. I bought a cheap one covered with glazed calico, pulled it up round a pole, making it as close as possible. It is just the size to cover one of Mr. Rivers' miniature trees. I use Gidney's Fumigator, and leave on the crinoline till the next morning, I then syringe the trees. The fly has no chance against the tobacco in so small a space, and the tree does not appear the worse.—KATE.

NEW PLANTS FROM JAPAN.

ABIES MICROSPERMA. Lindl.

AMONG the Conifers sent home by Mr. J. G. Veitch is one which, on account of the unusual smallness of its seeds, Dr. Lindley has named *microsperma*.

Mr. Veitch characterises it as a tree from 40 feet to 50 feet high, with foliage resembling the Spruce Fir in point of colour, and very glaucous on the under surface. The leaves are as long as those of *A. amabilis*, and perfectly silvery underneath. It was at Hakodadi.

TIMBER FOR STOVE AND GREENHOUSE BUILDING.

In reference to what is said in your last Volume, page 460, let me state that I have some railing of pitch Pine which has been out of doors for at least forty years, and is now quite sound. It may have had three or four coats of paint during the period. There has been no exudation of resin more than is common to most Pine timber.

The resin which exudes from such when exposed to the sun is not what pervades the wood as in pitch Pine, but that which has accumulated from the effects of injury or disease during the growth of the tree—*e.g.*, at knots, which are the ends of dead branches overgrown by the stem, and where the bark has been injured.

I am not aware that pitch Pine has any affinity for dry rot more than Oak. I have always considered it induced by circumstances independent of the nature of the timber.

There can be no doubt about the value of good red deal for the above or any out-door purpose (for which it is suitable) out of the ground. Pitch Pine will stand the ground almost as well as Oak.—K.

As I see in your last Number that a correspondent's inquiries about the varieties of wood fit for plant-house building have not been answered satisfactorily, I beg to offer a few remarks.

In a specification good red deal means nothing; if Baltic is added it is a different affair. We must condemn all American timber, although the carpenter will say it works so easily and takes such a good face. *Gettenberg* yellow deal is, although lasting, to be rejected; as a sash-bar it will twist till it strains the glass, and then the first frost breaks it. *Menel* does not come so good as it used to do, but more like white timber. *Dantzic*, although rather hard to work, will outlast any fir I have seen. Of course, no one would think of working sap; if it is objected to as being difficult to cut into small sash-bars, *Orega* or *Petersburg* are both good and fine. When pocket money was short I sat down to work and made some pit-lights, twenty years since, and they are, with the exception of the bottom of two sash-bars, as good as new. Mr. Robson's objection to Oak will be overcome if the plank is well seasoned before being cut, three-inch plank will take quite twelve months.

I think it a good plan to thickly smear the tenons of sashes with good white lead when they are put together. Carpenters are too fond of narrow rabbets in their bars. They are little trouble and look neat; but the glazier has to cut in the glass very light, and much mischief consequently arises.—H. B.

HEATING A VINERY BY A PIPE-FLUE.

I AM thinking of heating a vinery so as to give some assistance to the ripening of the Grapes, and to secure my bedding stuff from frost. My house is 33½ feet long and 13 feet wide, 9½ feet high at back, and 3½ feet at front. I am anxious to know if glazed or terra cotta pipes of six-inch bore would answer for a flue, by having 8 feet or 9 feet of brick flue nearest the furnace, as cheapness is a great object, provided it is permanent. I purpose having the furnace at the back of the house at one end, and to bring the flue under the floor, by the door, then along the front, and return by the back to the chimney at the furnace. I have a walk sunk 18 inches deep and 2 feet wide, within 3 feet of the front of the house. Should I bring the pipes (if they answer) along either the walls of this walk, or could I bring them along the floor near the centre of the house, and make them useful for bottom heat if I build a pit in my house? I shall be most thankful, if you think the pipe sufficiently strong to resist the heat, if you say what is the best material to use at the joints to staunch them, and if they can conveniently be cleansed of soot, &c., and if it is necessary to sink the furnace lower than the flue at the doorway. I know the return-flue should be higher than the furnace.—KATE.

[We have not had much experience in earthenware pipes, but have seen them answer. The greatest difficulty is in getting the cement to adhere properly to the joints, which it is unwilling to do to a glazed surface. But six-inch pipes will not do; let them be nine-inch, or even a foot would be better; and the end-, or at least the angle turnings, had better be brickwork; and so arrange the covers as to take off and permit sweeping the whole length of pipe-flue without disturbing it. We have two houses, each

36 feet long, heated in this manner, the pipes being Portland cement, and 1 foot in diameter. If you run your flue first along the front wall and return it at the end, and close along the back wall, you will have room in the centre for a bed about 5 feet wide, which being filled with fermenting material will help to heat the house, and be of great service to the Vines, and will be of infinite service in supplying heat to bedding plants wanting to be forced on. In the early part of winter it would be better not to have much bottom heat, the drier heat being more useful in pre-erecting plants; but by the middle or end of January you may begin to force if you want to increase your bedding stuff to any great extent, and from then up to the end of April your house, pats, and all, will likely be crowded. If you have good-fitting earthenware pipes, perhaps white lead would make as good a joint as anything; but cement may be tried. As pipes of twelve-inch diameter of Portland cement only cost some 1s. 6d. per foot run, and the joints require very little setting, this will perhaps be as cheap as anything. When you first light a fire in a house heated by a flue, let some of the ventilators be open, as there is always an offensive vapour arising from a flue when the fire is first lit, and perhaps an escape of smoke from even the best-managed. It is certainly better for the fireplace to be lower than any portion of the flue; but the flue may dip gradually at a doorway, or any other place in its course. Avoid abrupt turnings, and as the smoke rolls along the upper side of the flue let there be no obstruction, such as a direct perpendicular descent, in its course. Attention to these little matters will insure success.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

As the summer crops are removed, measure and dig or trench the ground before the autumn rains set in; in stiff soils this is of the greatest importance. Weeds at this season are very troublesome if any have been allowed to drop their seeds during the summer. The autumn-sown crops must be kept clear of them, or they will be soon overrun by them. Remove or dig in all decayed leaves, and all litter that stirs harbour for slugs. *Artichokes*, cut down the flower-stems of the late plantations as soon as done with, and keep the plants free from decayed leaves. *Cabbage*, continue to plant out the main crops. Keep the late seed-beds free from weeds. *Cypripedium*, the green pods of the large to be gathered if there are any apprehensions of frost. *Carrots*, slightly thin the autumn sowing, and keep them free from weeds. As soon as the main crops are full grown they should be taken up. *Cauliflowers*, continue to prick out the young plants under hand-glasses and in frames. A few may be potted in small pots and placed in a frame where they can have an abundance of air and light, and be protected from excessive wet. *Celery*, a few rows of that which is required for immediate use to be earthed up to the full extent of the leaves. It should at all times be thoroughly dry before earthing, or it will soon rot. *Lettuce*, plant some of the Cabbage kind for winter use into frames as they become unoccupied. The soil in which they are planted to be very light; but little air to be given until the plants begin to grow. Prick out on a warm border some of the Cox kinds, previous to planting them where they are to remain through the winter. *Mushtrooms*, keep the out-door beds protected from heavy rains by a good covering of litter. Maintain a regular degree of heat in houses containing beds, and guard against dryness. *Onions*, slightly thin the autumn sowing when they are a few inches high. Immediately the main summer crops are done growing, pull them up and house them when dry. *Parsley*, cut down a portion of the spring sown, so that it may shoot again before winter. Pot some good roots to place in any warm house for furnishing a supply during severe weather. *Potatoes*, continue to take up the crops as they reach maturity. Sort them before they are housed, as it will save much future trouble and waste. *Radishes*, slightly thin the late sowings of the Spanish sorts. If a succession of the common sorts is required, a sowing should be made in a frame. *Spinach*, thin the winter crop, leaving the plants about 9 inches from each other. Keep them free from weeds. *Tomatoes*, should there be any apprehensions of a frost, the unripe fruit to be cut and placed in some dry warm place to ripen. Fresh plantations of *Cabbages* and *Lettuce* should be frequently examined. Any that droop without an apparent cause should be examined at the roots, where, very probably, a grub will be found, which, if

not destroyed, will continue its ravages. Earth up the plantations of *Broccoli*, as they will now be growing rapidly.

FLOWER GARDEN.

This season has been most auspicious for the flower garden. The masses of colour still retain some brilliancy, and but for the falling of the leaves we might deceive ourselves into the impression that the summer was not yet over; but, alas! for the transient nature of all sublimary things! in a few more nights we may be visited by a frost which will lay prostrate the glories of our gardens. As there are many plants of which it will be desirable to preserve some of the old stock for blooming next year, it will be prudent to pot them as soon as possible, and to place them in a gentle bottom heat, or in a close pit, until they are somewhat established in their pots. Look over the arrangement of your beds, and mark and learn the errors of commission and omission. Secure what is good to add to next year's display, but remember that novelty and excellence do not always go hand in hand.

FRUIT GARDEN.

The fruit on the trees to be looked over frequently, and to be gathered as it becomes fit; for if left to get over-ripe it is liable to be blown down and bruised when high winds occur. As some decaying fruit is generally to be found for a few weeks after being stored, it is advisable to look over them occasionally, and to remove such fruit. Where it is intended to plant any fruit trees this season, the ground should be prepared at the earliest opportunity, and any fresh soil to be used for planting should be thoroughly exposed to the action of the weather, so as to have it in a mellow state when wanted for use.

GREENHOUSE AND CONSERVATORY.

Where there are many stove plants in the conservatory, it will be necessary, if the weather is cold and wet, to use a little fire heat; but it is necessary to be as sparing of this as possible, especially if there are other things in the house likely to be injured by being kept too warm. Use weak manure water for *Salvia splendens* and *gesneriflora* so as to preserve the plants in a vigorous state, and to keep them blooming as long as possible. The Chinese *Chrysanthemum* will shortly give a feature to the general display. Large plants may be taken up in showery weather, potted, and kept in a close frame or pit for a week or two, when they will flower equally well with others.

PITS AND FRAMES.

Continue to afford the young stock in these structures careful attention, and endeavour to get it well rooted and strong without keeping it so close or warm as to render it sappy and liable to damp off on the first approach of wintery weather, as is often the case with stock got up late in autumn, and then stored away in cold pits for the winter. Admit air freely, therefore, to all plants that are rooted sufficiently to bear it without flagging. Newly-potted off plants to be placed on a gentle bottom heat to encourage the formation of roots, but sufficient air to be given to prevent anything like weakly growth. Cuttings of *Scarlet Geraniums*, &c., may be still put in where it is considered that the stock of these is likely to be deficient. Secure as many cuttings as possible of any scarce plants which it is desirable to increase, while there is a fair chance of rooting them.

W. KEANE.

DOINGS OF THE LAST WEEK.

CABBAGES.

TRENCHING up ground where the main crop of Onions had grown, adding a little light manure to the surface, forking it in, and after rolling the ground with a light wooden roller, to break the knots of soil, and prevent potching with the feet, planting out the main crop of Cabbage for next spring and early summer, using chiefly the Matchless for this purpose, as giving early heads and a large return in little room. Watered when planted, and dusted round the plants with soot and lime, to prevent any slugs remaining having a pleasant nibble at the sweet young plants. The rolling of the ground as above specified having also some reference to these slimy genies, as without compressing the ground much, the refuges which they so much like under clods are much lessened; and if picking them up in a morning or evening, or trapping with Lettuce leaves, or enticing with brewers' grains are resorted to, they may also get these alluring morsels more easily without touching the young plants in their route.

A great ado all this truly, about common Cabbages; but to

have Cabbages when wanted, even such common things need attention, as a good many found to their cost last season, when there was a deficiency of these Cabbages when wanted. We will plant some more a month later, in order that if the winter should be very severe, and the frost very early, they may escape from being in a slightly decayed state, when those planted out now might suffer from being so full of juice and growing freely.

GENERAL KITCHEN-GARDEN WORK.

Planted out also Lettuces and Endives in open ground, and in turf pits where a little protection could be given them. Cleared away all Peas that no more gathering could be got from. Putting past those valuable sorts that had any pods nearly ripe, to be thrashed out on a wet day, and digging the ground and filling with useful autumn and winter crops, so that no space should be empty, and, besides, few things give a garden a more weebegone, careless, unsightly appearance than rows or quarters of decaying crops of Peas. As unlike our neighbours in Ireland, and some parts of England and Scotland, we have had few down-comers of rain that would thoroughly drench the crops. Watered Celery effectually, and when soaked in put on an inch or so of soil to keep the moisture in, and earthed up a little more for succession for table, giving that previously an extra watering, and in order to keep the heads sweet and clean placed a few ashes close to the stems. Gathered more Tomatoes, picking Cucumbers, &c., regulated the latter a little, and Vegetable Marrows, top-dressing those Cucumber plants in pots that are to have a little heat when needed, and went through the old Cabbage-quarters, removing all split Cabbages that nobody cares about now, and all decayed and decaying leaves to the rubbish-heap, where with short grass and refuse from the potting-bench, and pickings from flower-beds, a rare manure-heap will be formed, and the heat generated will be enough to destroy all seed weeds. Hoed and forked such ground, as it could be best managed, and run the Dutch hoe through the kitchen garden, as moist days may now be expected, and it is much easier to get rid of weeds when they are six lines in height, or almost imperceptible, than when they are 6 inches, to say nothing of 6 feet, to which height some fanciful people allow them to rise before they think them big and gigantic enough to be worthy of combating with their destructive skill.

STRAWBERRY-BEDS.

Got through the Strawberry-beds at last—it should have been done earlier, but better late than never. All runners were removed from plants put out this last season—say March and onwards. In addition to that, older plants rising two and three years old were thinned out a little, the smaller buds being removed and the strongest and boldest left and all the leaves attached to them, which leaves are beginning to brown sooner this season than usual, showing signs of ripeness of bud and an early winter. Plants so thinned will bear well a great many years, and hardly ever wear out if furnished with top-dressing every winter. Our usual time, however, is to take three years, chiefly that we may bring on our ground for rotation of crops, as Carrots, &c., dearly like to follow deep-trenched Strawberry-beds, and all the Cabbage tribe like to deep Onions. We follow the above course with our Strawberries, because our ground is close and stiff and rather cold, and we should lose and not gain anything by removing any leaves from the plants left. When thus cleared, the ground was forked slightly on the surface, and when convenient we will pull some fresh soil to the crowns, and place some rough manure between the rows. Whilst under such circumstances we would consider the cutting or moving off the leaves of a Strawberry-quarter as an act of barbarism, we would not consider such practice so thoroughly outrageous as some cotemporaries affirm under ordinary circumstances. We have seen Strawberry plants attain a large size in rich, light soil; and in a dry summer the leaves will be browned by August and yield nothing to the ripening and swelling of the buds. In such a case we would not hesitate to clear the rows of most of their leaves as soon as the fruit was gathered and runners secured, and if either a good watering or a good mulching could be given, we should expect to have nice green leaves close to the ground, and fine plump buds before winter, instead of brown, dried-up foliage waving in the breeze, and stunted little pin-headed buds at their base. In one word, we have seen cases where a scythe judiciously used, kept high enough above the buds, might be a very proper weapon to use however barbarous; but in most good Strawberry soils, consisting of strong loam with a touch of the adhesiveness

of clay to give it compactness, anything like the cutting down of the foliage by scythe or otherwise, must not be thought of, if fine continuous crops are desirable. The circumstances of the case must regulate our practice, rather than the sweeping assertions of authorities however otherwise trustworthy. No authority ought ever to lessen the necessity for thinking and considering for ourselves.

Went over a second time Strawberry plants in pots, removing every vestige of a weed, and every mite of a runner, and using manure water when any is necessary; and as now the dew is getting heavy, have placed a pinch of soot over the surface of each pot that the virtue may be washed in, and in a few days will give each plant a pinch of guano. These plants were very small when potted, but they are now large enough to my fancy, with bold buds standing above rather than below the rims of the pots, and the soil almost as firm as a brick being so full with roots. Ere long all attempts at mere growth must be relinquished, and October must chiefly be devoted to ripening the buds by giving all the sun possible, and allowing no more water than will keep the leaves from flagging, and for that little will be needed. For want of better arrangements the pots should soon be laid on their broad sides in heavy showers, as it will be easier to water than to keep them dry.

FRUIT GARDEN.

Went over all fruit trees, as dwarf bushes and standards, removing laterals, breastwood, shortening shoots, and even cutting leaves in two of Peaches getting a little too strong, to arrest growth and assist the maturation; and for this purpose all fruit trees in pots, as Peaches, Apricots, &c., under glass, will have little water, and all the sun possible, whilst to give the sun more power the air will now be diminished to a point of safety in all sunny days. Only let us get such wood as hard as Oak twigs and no danger of having plenty of bloom-buds. A few Figs in the open air have been dressed, to allow of this sun action. Our crop this season has been scanty, though the individual fruits were good; but this is of less consequence, as the second crop in the Fig-house is producing abundantly, though the fruit are not so fine as in the first crop. Some plants in pots in a cold house will have to be moved to a warmer place to perfect their fruit. Some of them are the *Singletoe*, which came out lately as a new, white, small Fig; though now having grown it, I find it the same as I discarded years ago, partly because I had too much of it, having the name of *Bacifido* and some other aliases, and which has been grown for some generations at Brockett Hall, in Hertfordshire. It is a fine, splendid, small, white Fig, and I understand Mr. Rulfit, the able gardener there, succeeds in having fruit from it almost continuously—at least as with other kinds he gets a good first crop, whilst in my case and that of some other friends, we have mainly to content ourselves with a second crop, the first crop having such a tendency to drop when very small. Any hint on this subject would be desirable.

ROADS AND WALKS.

Cleaned the sides of carriage roads that there might be neatness outside as well as inside; swept and rolled the walks, that they might be smooth and easy for the feet as well as nice to look at, as I think a piece of lawn quite as useful to walk on, and far more pleasant to look at than a walk rough with worm-heaps, and so green that really you can hardly make out whether it was intended for gravel or lawn. In this, as well as many other matters, well done is easy done. There is hardly a place of any size where the walks are not far too numerous. Walk-making, merely for walk-making, has been a perfect frenzy, and altogether apart from neatness or utility. In some fine places you may stand and count numbers of them within the reach of your vision, when one or two would serve all the purposes. That makes walks an indispensable evil; for, in fine scenery, even a fine walk, or a fine road, is such a break up as to be in itself an evil, and only to be allowed when kept nice, and its seen utility and necessity demonstrated. As the walk-making time is now approaching, our readers will do well to consider how they can keep those they have in the best possible condition, instead of increasing their number, or allowing some to remain as so many shallow ditches, for carrying off the surface water in the neighbourhood.

PLANTS UNDER GLASS.

Fresh arranged conservatory, removing everything the least faded; re-potted *Cinerarias*, *Calceolarias*, *Geraniums*, and *Humeas*,

and top-dressed hard-wooded plants previously to housing them ere long. Re-potted also Chinese and other *Primulas*, tied out young *Pelargoniums*, picked over the flower-beds, which, especially the *Calceolarias* lately so fine, suffered much from the storm of Sunday, and continued propagating bedding plants as much as could be got at, placing them in cold pits and frames that they might not be drawn weakly. We noticed two or three friends trying Golden Chain in heat. We hope they may succeed. It does best struck cool and airy with us at this season. In spring it strikes well in heat, though in the early part of the season we like to strike *Cineraria maritima*, as already detailed, yet in case the frost should be again severe in winter, we have put in some cuttings, and will secure some of the old roots. We notice that last week's seedlings of the above are recommended as the best. They certainly occasion far less trouble, but they are anything but best. I have some 500 feet of them, but you can detect a plant raised from a cutting ever so far off among them. My impression is, that the plants require two or three years to get their nice white colour. The seedlings have a dull, greyish appearance, instead of the rich silver white appearance of those raised from cuttings. Seedlings, however, are good, though not best.—R. F.

TRADE LISTS RECEIVED.

Descriptive Catalogue of a Selection of Roses, by William Paul, Chesham Nurseries, Waltham Cross.—Mr. William Paul has long been known as one of the great Rose authorities, and we have in this catalogue a description of the Roses in his collection, which appears to be not only a large but also a select one.

Descriptive Catalogue of a Selection of Roses, by Paul & Son, Old Nurseries, Chesham.—This is an excellent descriptive catalogue, and contains a very complete collation of all the best Roses in cultivation.

A Catalogue of Bulbs and New Plants, by James S. Pike, Wincinmore Hill.—This is a good selection of all the choicest new things in the way of florists' and general nursery stock.

Godwin & Son's Abridged Catalogue of Fruit Trees and General Nursery Stock, Ashbourne, is a small pamphlet of ten pages.

A Catalogue of Foreign and Native Grape Vines, by Wm. R. Prince & Co., Flushing, near New York.—In this catalogue we have a record of the names of 344 varieties of Vines, of which 243 are native American sorts whose qualities have been fully proved. What the merits and characters of these 243 kinds are we should be glad to know; but if they are all possessed of the characteristic foxy flavour, there cannot be much room for variety. We should like to know something more about these American Grapes.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications.

We cannot reply privately to any communication unless under very special circumstances.

VINEY (*An old Subscriber, Brighton*).—In converting your greenhouse into a grapeery, plant the Vines opposite the rafters inside. The two White Grapes to grow with your eight Black Hamburgs had better be one Royal Muscadine and one Buckland Sweetwater. You do not state your subsoil, but the border must be nearly 2 feet deep and well drained. If you refer to our No. 13, page 178, N.S., you will find full directions for making the border.

SPIDERS ON CUCUMBER LEAF (*Cucumbers*).—The gardener was quite correct, they have nothing to do with your miserably afflicted Cucumber leaves. They are swarming with red spider. The air of the frames has been kept too dry. Syringing under the leaves with sulphur mixed in soap-suds will be your only remedy.

VARIEGATED BALM (*A Subscriber, Bradford*).—It would not be true from seed. For 500 stamps you can have from our office "Greenhouses for the Many," and at page 43 is a description of Arnott's stove, and other modes of heating too lengthy for us to extract.

WORKS ON THE CUCUMBER (S. A.)—A Subscriber from the *Commencement*—Both the books you mention are out of print, but may be met with at the second-hand book-shops. The editions given in the *Cottage Gardener's Dictionary* are by a good authority.

BUILDING A VINEY (An Old Subscriber)—You propose building a viney 60 feet long and 15 feet wide in Yorkshire. If the natural advantages of your place be good, we see no reason why your undertaking may not become a good investment if you go the right way to work. First of all, secure good drainage; and though you mention you do not intend to put a drain at all, we do not let that be the best method. The line of building, as you say, it will most likely have to be done after, and may be more difficult then. And as coals are cheap in Yorkshire, a good fire may serve your purpose. Keep the house, or rather the border, above the level of the surrounding ground rather than under it, and if you only want to grow Grapes such as the front part of a hot-house, only if the front wall be more than 3 feet high there ought to be glass; if below that, sliding shutters not less than 2 feet square and 3 feet apart may be worked in for ventilation. Rafters and sash-bars fastened to a parline in the middle will do very well if the whole of the glass is to be fixed, which it may be if thought well of, having a board not less than a foot thick to act as a flap to give air at top. This, in addition to the doors at the ends and the front shutters, will do very well. We do not fully understand your ideas about the glazing; but assuming you to use twenty-one-ounce glass, squares about 8 inches wide and about 20 inches long work in very well, it is better not to have them any wider than the 8 inches, but to be cut in squares as the house is to be used only for Vines, wires stretched the whole length of this house and about 1 foot from the glass and 1 foot from each other answer as well as any; and if the end fastening be good, any small wire will bear them from the rafter or glazing-bars, and you can train on any wire you like. At all events, let good materials for your Vines be chosen at the beginning, and other things will present themselves to you in a manner that will prompt you to understand their wants; and our columns are ready to reply to any further communication you may think fit to make.

GRAPES NOT COLORING—FIGS NOT RIPENING (A Three-year Subscriber)—It is an easy matter to account for this, but not obviously so at certain times, as there is something of an unaccountable capriciousness in certain Grapes to do so. Generally speaking, there is something wrong when they do not colour well, as, when they begin to change, the transition from green to black ought to be rapid—no hanging in the red state. Neither do all the berries in a bunch come together, some being green while others are quite black. This is when all is right. It sometimes, however, happens that a too heavy crop occasions the berries to colour badly, or the growth of some other crop on the border occasions their doing so, or what is quite as bad, their shanking. Perhaps this is the case with our subscriber's Vines. The best remedy of the kind, and of the greatest value, is to cut down the border; but it may be all neutralised if the border is used for flowers, and such things as Fuchsias are allowed to cheat the Vines. Figs like a great deal of water while in a growing condition, and they also require the full sun, which they cannot have at the back of a viney; it is therefore only a few fruit at the top that are likely to do well. If the evil should arise from the roots of trees or other things getting into the border remove them; and if the Vines require it, lift them up and replant, after securely making the border afresh in the manner described in former Numbers of this Journal.

COTTAGES' HORTICULTURAL SOCIETIES—The undersigned would be much obliged to any reader of the *JOURNAL OF HORTICULTURE* who would send him names and addresses for the formation of a society.—J. H., 3, Boulevard Street, Fleet Street.

INSECT ON CABRAGES, &c. (A. C.)—It is the *Aphis brassicæ*, or cabbage louse. Tobacco water will destroy it if applied with a syringe. The Brussels Sprouts when cut may be cleared from them by washing in three or four waters, having salt dissolved in the water.

VARIETIES (R. E. T.)—Twelve pages of questions from one reader by one post like yours would soon defeat the object we have in view, and we should be obliged to answer the first question only. 1, Vegetable Marrows and Custards are preserved like common Gourds and Apples for winter use. 2, Reigate sand is only best for cuttings. Any sand is as good as any other for mechanically making a soil more porous or loose for pot plants. 3, We do not know yet the way to put Grapes or Figs in a paper, but to wrap the bunches in a paper, then in a bag with bran or chaff or husks of hemp. 4, Fuchsias to be now set to rest till the spring. 5, Cuttings made now of *Helleborus*, *Verbenas*, *Geraniums* to remain in the pots over winter. 6, Rooted cuttings will keep better in a greenhouse than in a brick pit. 7, It is not worth the trouble to cuttings of *Myrica* in winter of this season. 8, It will not improve the circles for Rose trees to have variegated plants to edge them. 9, The best sorts of edging plants are named every year. Consult the indices of the last three Volumes. 10, Very rotten dung is very good indeed for Deciduous, as Mr. Beaton proved in the Experimental Garden. He also proved that flies and bugs are "erased" by cleaning the parts with pure spring water as well as if they were cleaned with all the decortions in the world. The expense is the time doing it. Every plant in cultivation can be kept free from all the insects by common spring water if we could afford the labour to do the work.

SEEDLING GERANIUM (George Holmes)—Your seedling Geranium is very good, and of no value there are so many like it, and they are all descended of the blood of Rubens. You would not know your own seedling from a bed of the best Rubens now on the Kose Mount at the Crystal Palace, and we have many as good.

Gas Stove (Noctuo)—If the fumes arising from the burning gas are carried away by a tube through the roof of the conservatory no injury will be caused to the plants. If you will buy "Greenhouses for the Many," as recommended to the most corresponding subscribers, you will see, in various directions for heating by a gas-heated small boiler, as well as by a gas-stove, with illustrations.

SEEDLING TROPÆOLUM (A Regular Subscriber)—Of the Scarlet, No. 1 has the advantage over Perfection in being deeper and richer coloured, and is the best of the three described as compact-habited sorts (marked 1, 2, 3), which, being similar in character, are not all required. Of the other Scarlet,

No. 9, apparently of intermediate habit, is far the best—indeed the best of the whole as regards the form of the flowers, which is very perfect. No. 14, if not coarse-habited, is also fine, having large, well-formed, smooth, orange-scarlet flowers. No. 10 and 11 are inferior to the large-flowered. Brilliant of the darks. No. 8, with flowers smaller than *Nigris*, but described as of good bedding habit, is apparently good, having firm smooth flowers. An unnumbered one (apparently No. 4, which otherwise is not seen), with larger flowers, also appears to be superior in smoothness to *Nigris*, but was rather faded. No. 7 is not so good as the foregoing. Of the yellows No. 6 is distinct and good as regards colour—a golden yellow with large feathered blotch on all the petals. No. 5 is near Gamut in character, but a shade or two paler; its value would depend on its habit, which looks promising enough. No. 12, pale straw-coloured, is too loosely formed. The border is 15, 6, 8.

GRAPES IS A GREENHOUSE (A Subscriber)—Neither the Muscatel, nor the Canon Hall Muscat, nor the Alexandrian, will ever ripen well in your greenhouse, which is never heated. We should have a furnace and flue to ripen these Grapes, if the Vines twelve or fourteen years old are healthy. If you do not obtain artificial heat you must protect these Vines, and plant in their place the Royal Muscadine and Buckland Sweetwater.

NAMES OF FRUIT (Lighton)—The Pear is Williams' Ben (Chrétien); the scarlet Apple Red Astrachan; and the Russet Golden Russet.

UNCREATED GRAPES (A. T. W.)—They are so much affected by what is technically called "the spot," that the berries are totally gangrened. We have little hesitation in saying that it is occasioned by the want of sufficient activity in the roots, so that they do not supply sap in quantity sufficient to keep pace with the demands of the growth, which is the cause of the berries' growth and ripening, such ulceration would not appear. The roots might be kept warmer by exposure of the border to sunshine, and covering at night and during cold days.

WORK ON FLOWER GARDEN DESIGNS (A Subscriber)—"The Ladies' Assistant on the Formation of the Flower Garden," can be had from our office from Mr. J. C. Fisher, 66, Abchurch Lane.

FERNS IN A COOL VINEY (A Subscriber)—The species of *Chelidonia* mentioned—namely, *viscosa* and *elegans*, together with *Platyloma calcicola* and *Notioclæna chrysochylia* will live in the cool viney from which frost is only just excluded, provided the roots and the atmosphere are kept dryish. *Pteris secula* at no time requires heat, but it likes more moisture, and a cooler atmosphere than the foregoing. We should doubt if *Adiantum concinnum*, *Pteris aspericulis*, *tricolor*, and *cretica albo-lineata*, would succeed under such circumstances, especially *P. tricolor*, which comes from the hot Malay Islands. Still, however, many stove Ferns will live in a low temperature if kept quite at rest, and these may do so.

WINTERING GERANIUMS (A Lady)—The best plan, in your case, was told last week. But now the Geraniums and the Fuchsias to be pruned in the old wood just before the frost, and nothing more to be done to them till March, except seeing the mould does not get quite dry in the pots they are now in. The system of keeping plants in the open air during the winter, which has been called Harry Moore's system in our pages for the last dozen years; but your plants and pots are yet too small for that plan.

TOMATO (J. T.)—There are several varieties of Tomato, and that which among your plants differs from the more common, is probably the "Cherry-shaped." It is a well-known kind.

TULIPS AND GLADIOLI (S. T.)—We never give the names of seedsmen. Let the seedling Gladioli remain, but well covered with coal ashes in winter to exclude frost.

NAMES OF PLANTS (M. Sturge)—It is *Clitorea ternata*, introduced as long ago as 1739. It is one of the most beautiful of the climbers among our stove perennials. It is called *ternata* from being first discovered in Ternate, one of the Molucca Islands. A drawing of it, with directions for its culture, are in vol. vii of Paxton's "Magazine of Botany." (*R. E. S.*)—*Hoya bella*, (*H. G.*)—Nos. 1 and 3, indeterminate scraps without flowers; 2, seedling of *Pteris aquilina*. (*G. B.*)—Only nineteen plants sent for names at once! Have you never seen our notice that we cannot name more than six at one time? 1, *Pteris tremula*; 2, *Cyrtium falcatum*; 3, *Pavalia canariensis*; 4, *Adiantum hispidum*; 5, *Diplazium decussatum*; 6, *Pteris hastata*; 7, *Adiantum forosium*; 8, *Adiantum assiuale*; 9, *Pleopeltis Billardieri*; 10, 11, *Gymnomorpha ochracea*; 12, 13, *Adiantum cuneatum*; 15, *Asplenium tuberosum*; 17, *Asplenium fibulifolium*; the rest are *Claspedium*. (*Agg.*) Let the seedling plants appear to be some *Cassinia*, which we do not suppose would endure our winters exposed. We do not know the *Roze Bean*. The name of Wattle is given in Australia to several species of *Acacia*; thus, *A. mollissima* is called the Black Wattle; and *A. dealbata*, the Silver Wattle (*A. Coley*).—It gives much trouble to send us leaves without flowers. 1, *Hoya*, a bulbous plant, which, if so, it requires heat while growing, to be potted in good peat and loam, mixed with pounded brick or old lime rubbish, and well drained, to have the full sun, to be moderately watered, and in winter to be rested in the cooler temperature of a warm, dry greenhouse; 2, *Nerium oleander*; 3, some *Rhododendron*.

FLOWER SHOWS FOR 1861.

NOVEMBER 6th and 7th. ROYAL HORTICULTURAL SOCIETY. (Fruit and Chrysanthemums.) *Garden Superintendent*, G. Eyles.
NOVEMBER 12th and 13th. STONE NEWINGTON CHRYSANTHEMUM SHOW.
See, p. 11.
NOVEMBER 14th and 15th. CRYSTAL PALACE. (CHRYSANTHEMUM SOCIETY.)
See, p. W. Houghton.

POULTRY, BEE, and HOUSEHOLD CHRONICLE

JUDGING POULTRY.

It seems imperative that some other means of judging poultry, &c. should be adopted than the plan now in use. Nearly all parties seem displeased at some point or other; and my opinion

is, that unless a change is adopted, very soon many respectable exhibitors will cease to send to shows.

I think a fair course to pursue would be to solicit opinions upon the subject of all connected with shows and exhibitors, and so obtain a universal voice in the matter.

For my own part, as an exhibitor, I find fault—I condemn entirely the plan of Secretaries sending the numbers of their pens to exhibitors, for more than one person is aware that a Judge is often invited and made welcome at certain estates of breeders, where the marks, general character of the stock, &c., could be carried in the eye and judged accordingly.

Again, the judgment of one person is not sufficient to satisfy strangers as to the capabilities of those judges. If a number were invited to judge separately, placing their opinion under cover on paper, the result must be more satisfactory. For example, take the Crystal Palace. In the advertisement for next Show, they should invite persons who are known breeders, and can show by having been exhibitors, poultry fanciers, &c., that they must understand to some extent, to come on such a day. The Secretary first numbering, quite indiscriminately, all the pens, each person shall pass through the Show singly, write on a list, containing his name and address, his judgment, placing them as usual—1, 2, 3 prize, Highly Commended, and Commended, in this form—

Opinion of

Address

State if Exhibitor at this Show or not. [Yes or No] If so, what No.

If not, state if a Breeder of poultry.

Arbitrators—Messrs. Baily & Hewitt.

All present, for a certain limited time, and each placing his judgment with the Secretary, who shall then proclaim "state of the poll, &c."

Another plan I would advise, not to give the chance in chicken shows of stating such barefaced and palpable untruths as to ages as were told at the Crystal Palace. Chicken shows are not altogether good at any time; but if they must exist, be very severe in rules laid down that they are the chickens of the year named, but avoid the age being required to the day. Almost as well have a register and state the moments, &c.

I trust you will excuse my lengthy epistle. Many friends of mine are of the same opinion as myself; therefore I write as I were jointly, and have no doubt if you put the question as I mention you will find plenty of replies, and not much variation.

I would not do away with the office of Judges, the present two (Messrs. Baily and Hewitt) should still give their opinion the same as the rest, but their office should be that of arbitrators if necessary.—T. B.

[We insert this communication in the hope of eliciting opinions from our readers. We fear, although such a system, under stringent regulations, might be likely to secure impartial judgments; yet it would involve so much delay, and impose so much extra trouble on the Secretary, that we believe, unless well paid, no one would undertake the office, already sufficiently laborious and sufficiently attended by disagreeables.

If a judge possessing a competent knowledge and of known integrity can be found, economy, rapidity, and undivided responsibility are best consulted by his dictatorship. But never should one judge be appointed to decide upon one class—he is liable to the justified suspicion of knowing too much about the birds exhibited.

But, in every instance, we should prefer two or three judges—not mere ciphers only serving to screen the real judge from responsibility, but men really having a good knowledge of fowls.

Let us avow, however, our decided opinion that generally the awards are correct. There are mistakes made occasionally, but they are very rare. Sometimes the awards are apparently made

from corrupt motives, but these occurrences we are quite certain are still more rare.

Before any one exhibits he ought to make one resolve—"If I lose the prize, I will not lose my temper." With many men this resolution would be more easily made than kept; and the clamour we have sometimes heard raised in an exhibition-room by disappointed exhibitors, has always been as unreasonable as that of the spectators who went to the theatre to see a man get into a wine-bottle and rioted because he did not do so! If they had rioted one another because they had shown an error of judgment, they might have been excused; but they never suspect error in that direction.

Neither does it ever seem to occur to exhibitors to inquire—"Who does an exhibition benefit?" Certainly not the Committee or the Secretary—they are certainly losers of time, and too often losers of money. Neither does it benefit the Judges, for they rarely ask for more than their expenses, and too often do not have them paid. The benefit then is chiefly to the exhibitor. Poultry shows afford him an opportunity of obtaining superior specimens, of selling his surplus stock, and of making public the merits of his birds.

Such are our impressions relative to those connected with poultry shows; and we record as our unbiased opinion, that they are usually well and honourably conducted, and are altogether beneficial to the community. The exceptions are very few, and, as in other transactions, these exceptions prove the rule.

Our columns are open to those who agree with, and to those who dissent from, us; but nothing must be sent to us anonymously, let nothing be said that a man would be afraid to say standing on the centre pen in Bingley Hall.

We will conclude with some extracts from a letter we have received upon the subject:—

"I once did accept a very urgent request to act as referee at a poultry show, some gentlemen amateurs soliciting as the actual arbitrators, and I was given especially to understand my duties would begin only in case these gentlemen should differ in opinion so much as to go on no farther; but they hoped my position would prove a sinecure altogether." At first I declined the proposal, but a second pressing but truly courteous note made me yield compliance—a circumstance I have always regretted.

"I duly arrived on the ground, and, after a delay of some time, the Judges proceeded to duty, leaving me with the Committee to take a glass of wine, or employ my time as best I could. Time passed on hour after hour, and yet they made no application; the visitors were coming in at mid-day. I had read the *Times* almost through, and I felt assured if they wanted me at all they would go through every class before any application was made. Time still progressed, but at length they did come, when I found, to my utter astonishment, they had barely completed a half of their duty. After an abundance of talk in support of their relative divided opinions—for though 'referee,' they would not submit to me as such, but evidently considered me as one only of themselves, and 'only a voice among many'—I at length pulled through two disputations carried on, purely as though I had not a voice to control, but simply to discuss in any way—in fact, I could scarcely speak, so disputant did they become among themselves. Of course, much of this took place before visitors, at least in earshot of them, and I was repeatedly called to, 'Go in yourself and finish it, and leave them to quarrel it out, for it will be time to close directly.' Of course, though similar requests were urged by various exhibitors, I did not go as desired; but, at last, the show was finished, myself acting with them for the last some twelve or fifteen classes, and suggesting most of these latter decisions.

"After I was at liberty I took a stroll along the previous classes in which I was not consulted at all, and the prize cards being up; I found in two different first-prize pens a humped-backed bird in each, and a rosy-combed pullet in a second-prize Game pen!

"I would not myself accept again an office so painful, and so completely unsatisfactory to my own notions of common rectitude for any amount of emolument that could be preferred me in return.

"Poultry judging is no sinecure I can assure you, and at best the duty is a thankless one, nor do I myself believe any mode of determination will prove satisfactory to all. Dissenters will always push their way, if clashing with their own success, to every plan, however well reconsidered and advisedly carried

out, and let them be altered as frequently as they may be to suit the views of the time being.

"Writers on the subject usually know little of the financial management of poultry exhibitions. You will, perhaps, be astonished to learn, that although (as you know) my stipulation is for expenses out of my own pocket, giving my services gratuitous, I only some fortnight back reckoned up more than forty meetings that have never refunded me a single farthing of these outlays. The replies I receive are either 'They are very sorry there are no funds;' 'The Society is broken up;' or by preserving a rigid silence to any application, and that, I am sure, from parties who in their own affairs would certainly not thus compromise their position in society.

"I have more than once been fettered to a drag-chain colleague, and was actually once asked by a volunteer arbitrator (who was a very spirited local money supporter of the Show, and had pressed forward to be allowed by the Committee to assume office) 'Now, as I don't know anything of these things myself, pray which are the Dorkings? for I only took office to benefit the Society, and knew I should be right enough with you or —.' What a gratuitous help!

"But the next item is *time*. There are plenty of shows open at 10 to visitors, and close the same evening; one hour, or little better, being devoted to arbitrations, after previous penning being made complete of the birds the same morning, the Committee enjoining it must be opened as to time specified. None but uncontrolled, and diligent, well-practised eyes can do it at all in that period."

NORTHAMPTONSHIRE POULTRY SHOW.

THURSDAY, SEPT. 26TH.

We have often had occasion to speak of the supineness of those connected with agriculture when poultry is the subject; but here we must change our note, because the progress made justifies us in saying, it was the largest and best we have ever seen in the county. We think ourselves justified in devoting a little, to remark that the advances was not confined to poultry, but was apparent in every department, beginning with the locality that was chosen. It will be difficult to imagine a much better spot than the racecourse; and we are bound to praise the enterprise that encountered considerable expense, with only half a day's admission besides the subscriptions to depend upon to meet it.

This meeting is a holiday wherever it goes. From the concourse of people that attend it, the number of entries in the different classes, and the perfection of its arrangements, it is more like that of the Royal Agricultural than any we know, except the Bath and West of England. On Thursday the racecourse was covered with cattle, while the hoarding that surrounded the yard supplied the shes and stails in which the competing horses were shown. Outside the yard hundreds of acres were being ploughed by two horses, four horses, six horses, and by steam. The latter will, we think, swallow up the former. Then there were military bands, flower and fruit shows, and exhibition of roots. In the afternoon presentation of colours to the Northampton Rifles, and dinner in the pavilion at three.

We are very partial to these large gatherings, and during the many years we have attended this county meeting we have never seen anything that would interfere with the belief they are productive of much good. Outside the yard the road assumes the appearance of a fair, where every sort of sport is carried on, but everything appears to be done in perfect good humour, and every one seems to be on his good behaviour. One thing we most gladly note, and that is, we visit no place in our peregrinations where so little swearing or bad language is used. Swearing would appear to be uncommon, and may it long remain so.

It was always wished to encourage at an agricultural meeting the breeds most useful in a farmyard, and it will not, therefore, cause surprise that *Dorkings* are the most numerous; and if we add thereto, that one of our oldest and best Dorking breeders, the Rev. F. Thursty, has aided his neighbours with counsel and birds, that will give the cue to unusual excellence. There were thirty-five pens in the Dorking classes. The old birds were many of them in bad plumage from moulting, but their quality left nothing to desire. Mr. John Shaw, of Hensbury Hill, took first and second prizes, and Mr. Wood third. Seven out of eleven pens were in the prize sheet. There were nineteen entries

of Dorking chickens. We do not hesitate to declare this a first-rate class, and to say that many pens shown here will (barring accidents) figure in larger prize lists than Northampton. They sold freely at the prices put upon them. Mr. Shaw, again, took first and second prize. Mr. Tatham, of Kingsthorpe, took third. The Rev. Mr. Thursty, Mrs. Harris, and Messrs. Dawkings and Wood, all deserved more than a "high commendation;" but there was nothing more to give. There was also a marked improvement in the *Spanish*, both adults and chickens, especially the latter. These brought eighteen pens. Mr. C. Wright, and Messrs. Rogers, Bull, Smith, and Tatham took the prizes. The *Game* fowls shown by Mr. H. Shield, of Northampton, were so far superior to anything else that was shown in the same classes, that they achieved an easy victory. There is not the improvement we look for in the *Game*. *Cochin-Chinas* were very good, especially the cock in Mr. Brown's first-prize pen. *Hamburghs* were weak as usual. The "Distinct Breeds" brought *Silkie*s, *Bantams*, *Malays*, and *Brahma* *Pootras*. There were also shown as "Extra Stock" three pens of remarkably good *Game Bantams*. They were not for sale, or they would have readily found purchasers.

There were excellent pens of *Aylesbury Ducks*, but the best lost its position by having a ruptured Duck in it. Here, as elsewhere, the *Buenos Ayrens* were good and numerous. It would seem as though they intended to become nearly, or quite, the most numerous of the Duck classes. Messrs. Smith and Shaw took prizes with them and the *Rouens*.

The *Turkeys* were very good.

An extra prize of £1 offered for the best pen of fowls in the Exhibition, was awarded to the first-prize Dorking chickens, the property of Mr. John Shaw.

So far as could be known when we left the yard, the meeting was a decided success. We mention this not because success is a novelty to this Exhibition, but because on this occasion more expense was incurred than usual.

Mr. Bailly was the Judge.

BRIDGNORTH POULTRY SHOW.

For a number of years past it has been generally admitted that Bridgnorth Poultry Show has been one of the most popular throughout the midland counties, no small proportion of the public excitement arising, without doubt, from the extraordinary interest always manifested by several of our principal breeders of exhibition fowls, to secure to themselves the much-coveted silver cup, value seven guineas, so liberally offered by the Committee for the best collection shown by any single proprietor. As the number of pens entered for this special prize in former years was left quite unrestricted on those occasions, each competitor not only exhibited all the gens in his possession, but also got together as great an amount of tolerable specimens as attainable to still farther increase his chances of success. This year, however, the Committee limited the number of pens competing, and as a natural sequence, the collection as a whole fell short of the aggregate of preceding years—in fact, the only party who now ran hard for the premium secured it—Mr. Martin, of Claines, Worcester, who on several former occasions had ranked among the unsuccessful ones, but as invariably stated he would never relax his exertions until he did win it. The fact that the present winner had in previous years shown even by far a better collection than at this time, and was then defeated, shows beyond controversy that on the peculiar conditions imposed by the regulations of past years hung the great popularity of the Meeting; and, possibly, the discontinuance of any restrictions in future would at once restore all the enthusiasm, the loss of which on this occasion seemed so universally regretted by the visitors assembled. We heard with sorrow that personal or family illness had precluded altogether entries for this cup, from some who in bygone years struggled to the utmost for its possession; and repeatedly we heard the inquiry, "Where are Chune, Peters, Robbard, &c.?" each of whom had rejoiced in the ascendancy at some previous occasion. We indulge the hope that in 1862 the spirited rivalry of former meetings will be perfectly restored. One fresh arrangement of this year, however, seemed a most advisable one—viz., to again hold the poultry exhibition in a tent upon the field, in connection with the other agricultural produce generally; as during the past few seasons we heard of visitors who actually left Bridgnorth without seeing the poultry at all, and even going so far as to express their conviction that

no poultry whatever was exhibited. So singular as such an assertion may appear, it is not the less true, but under present arrangements it is impossible such a contingency can occur.

The *Cochins* headed the list, and here Mr. Bates, of Edgbaston, Birmingham, attained an essay victory with his well-known pen of Bufls, although other colours competed. As we have so frequently spoken of late in terms of well-merited praise of these birds, it would be superfluous to repeat our opinions. We cannot, however, pass them by without dropping a friendly hint to their owner. He is quite over-exhibiting them. The cockerel, admittedly, is a bird of that happy temper that would make himself quite as comfortable in an exhibition-pen as when enjoying all the advantages of his home "walk." Not so the pullets; they manifested unmistakable symptoms of unhappiness and discomfort, by raising the feathers on the head and shaking it continually sideways—the best of all possible proofs that condition is waning. It is really a pity to exhibit so perfect a pen so continuously; for we were informed that for three consecutive weeks they have been in competition—a trial quite too much for any fowls, and still more especially chickens. The second-prize Partridge-coloured Cochins were also very good. In White Cochins, Mr. Bates was again the successful one, although Mr. Chase was but triflingly in the rear.

The *Grey Dorkings*, that hitherto at Bridgnorth were always good, were this year quite a deficient class.

As to *Game fowls*, in which variety condition alone is so all-important, we hardly anticipated a very perfect collection, it being just now the very midst of moulting time. This temporary imperfection was peculiarly visible in the "Single Game Cock" class, the whole of which were in deepest pin-feather. Still we willingly admit, in the Game classes were to be seen many fowls that some six weeks to come would add most materially to the credit and interest also of any poultry show.

The *Hamburgh* classes, though not numerically well filled, were decidedly good. Nor must we fail to favourably mention some of the best *Poland* pullets (Black with White Crests), we have seen for several years past.

The two prize pens of *Spanish* were "alone in their glory," not a single opponent. They were very good birds, but quite out of condition.

In the "any variety class," Mrs. Blay, of Worcester, showed a pen of very singular *Polands*, the whole of the bodies being of an exquisite metallic blackness, combined (even in the pullets), with feathers formed very similarly to those of the Cormorant. The cock's crest was a bright bronze colour, but with the exception of a buckle-feather or two, the pullets were not in any way a match to their male companion. Their singularity and marvellously capital feather, however, caused them to be very attractive.

Some first-class *White-booted Bantams* were shown in the Bantam class, open to all breeds.

To say Mrs. Seamons, of Aylesbury, took first and second prize for *Aylesbury Ducks*, is singing one of the oldest songs of the season. They stood out like giants among their opponents; and we heard a very wealthy landed proprietor say jocosely, "Mrs. Seamons, to give fair play, ought to be compelled to enter her Ducks in the Geese class." A friend of the speaker retorted, "Do you think you could persuade the lady? I fancy not." In the united class for all other varieties of Ducks save *Aylesbury*, Mrs. Wolferstan (Miss Steele Perkins), of Stafford Hall, near Tamworth, exhibited a pen of *Buenos Ayrean Ducks*, quite able to support the prestige of that lady's strain of this beautiful variety. They were not only very small, but in exquisite plumage, and being entered at the unusually low figure of two guineas, they were speedily "claimed," and we were informed the lucky buyer would not re-sell them although he could almost have doubled his outlay. The remainder of the class was composed entirely of *Rouens*, they being also of very excellent quality.

As "Extra Stock," George Pritchard, Esq., M.P. for Bridgnorth, showed a pen of beautiful *White Call Ducks*, another of domesticated Wild Ducks, and a third as *Black Rouens*; these latter were, as most amateurs will suppose, *Buenos Ayrean Ducks*, all three of the pens being of great merit were highly commended.

The rule band of the Bridgnorth volunteers played exceedingly well at intervals throughout the day, and excited much applause; the uniform of this band is very peculiar. The old adage that "practice makes master" was amply illustrated in the system and management of the whole Exhibition; the poultry-

tent, indeed, was closely filled with visitors during the entire proceeding.

The whole of the poultry was promptly returned at the close of the day without accident or mishap of any kind—a feature we strongly recommend to every Committee of Management in such exhibitions, as tending, perhaps, even more than any other to the repute and success of future meetings of their respective societies.

As on former occasions, the arbitrator was Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, near Birmingham.

FOR CHICKENS OF 1861.

COCHINS—CHINA (any colour except White or Black).—First, H. Bates, Edgbaston, Birmingham (Bufls). Second, J. B. Walthew, Aughton, Ormskirk (Partridge). Highly Commended, J. B. Walthew (Partridge). Commended, E. Chase, Moseley Road, Birmingham (Bufls).

COCHIN—CHINA (White or Black).—First, H. Bates, Edgbaston, Birmingham (White). Second, R. Chase, Moseley Road, Birmingham (White). Highly Commended, H. Bates.

DORKINGS.—First, J. Whittington, Wootton Wawen, Henley-in-Arden. Second, Mrs. Wolferstan, Stafford Hall, Tamworth.

GAME (Black-breasted and other Reds).—First, A. Dyas, Madeley (Red). Second, J. Martin, Worcester. Commended, A. Dyas (Red).

GAME (White and Piles).—First, A. Dyas, Madeley (Piles). Second, J. Barnforth, Holmthorpe, Huddersfield (White).

GAME (Duckings and other Greys and Blues).—First, A. Dyas, Madeley (Duckings). Second, Miss Beldon, Park Cottage, Bradford (Duckings).

HIGHLY COMMENDED, E. Chase, Moseley Road, Birmingham (Duckings). **GAME** (any other variety).—First, A. Dyas, Madeley (Black). Second, J. Martin, Worcester (Black).

GAME COCK.—First, Cherrington, Allcott (Brown-breasted Red). Second, A. Dyas, Madeley. Commended, Cherrington, Allcott (Brown-breasted Red).

HAMBURGERS (Golden-pencilled).—First, J. Martin, Worcester. Second, R. Robson, Tulip, Monkswearmouth, Sunderland. Highly Commended, H. Bates, Edgbaston, Birmingham.

HAMBURGERS (Golden-spangled).—First, J. Martin, Worcester. Second, J. Barnforth, Holmthorpe, Huddersfield.

HAMBURGERS (Silver-pencilled).—First and Second, J. Martin, Worcester. Highly Commended, Miss Beldon, Park Cottage, Bradford.

HAMBURGERS (Silver-spangled).—First, J. Martin, Worcester. Second, Countess of Darnley, Parkhill Park, Commended, Miss Beldon, Park Cottage, Bradford, Yorkshire.

POLANDS (Black with White Crests).—First, J. Barnforth, Holmthorpe, Huddersfield. Second, Miss Beldon, Park Cottage, Bradford.

POLANDS (Golden-spangled).—First, withchild. Second, E. Chase, Moseley Road, Birmingham.

POULTRY (Silver-spangled).—First, Mrs. Blay, the Poplars, Gregory's Bank, Worcester. Second, Miss Beldon, Park Cottage, Bradford.

SPANISH.—First and Second, J. Martin, Worcester.

ANY OTHER VARIETY.—First and Second, Mrs. Blay, the Poplars, Gregory's Bank, Worcester (Black *Polands* and *Andalusian*).

BANTAMS (any other variety).—First, Mrs. Wolferstan, Stafford Hall, near Tamworth (East Indian). Highly Commended, R. Robson, Tulip, Monkswearmouth, Sunderland Game.

DUCKS (White *Aylesbury*).—First and Second, Mrs. Seamons, Hartwell. Commended, Ramforth, Monkthorpe.

DUCKS (any other variety).—First, Mrs. Wolferstan, Stafford Hall, near Tamworth (East Indian). Second, J. Holme, Knowsley, near Prescot. Highly Commended, Mrs. Knock, Bridgnorth (Rouen); J. Holme, Knowsley, near Prescot.

EXTRA STOCK.—Highly Commended, G. Pritchard, Esq., M.P., for Bridgnorth (Buenos Ayrean Ducks, Domesticated Wild Ducks, and White Call Ducks).

JUDGING GAME FOWLS—THEIR HACKLE.

BEING an exhibitor of poultry, I have thought it well to write you for the purpose of expressing my hearty concurrence in your remarks, relative "to the exclusion of poultry from our shows that are privately marked," contained in your Journal of the 17th.

It is a matter of deep regret that so much dissatisfaction has been caused to exhibitors by some of our Judges, who, no doubt, know the private marks of most of our largest breeders of Game fowls, and who allow these marks to have much influence over them in giving their decision. I know that every exhibitor is a little prejudiced in favour of his own birds at our shows; still I have no hesitation in saying that the best bird does not always win, consequently dissatisfaction arises. The Judges should bear in mind that there are plenty of people who visit the various shows who know quite as much of poultry as they do, and I am afraid that our poultry shows will soon become extinct unless there is a little more uniformity amongst our Judges in the judging of Game fowls. Some will tell you that a pure-bred Game cock should have short hackle-feathers; others will tell you that this is all moonshine, and the longer the feathers are the better the breed. Now, it so happens that a case of this description has recently come under my own observation, where a bird was deprived of the prize by one Judge, on account of the length of his hackle, but on being sent to another show (the Sheffield) he had the first prize awarded him. Now you could probably tell me which is right and which is wrong. In con-

clusion, I will just remark that I think it would be well if our Judges would agree on the principal points about Game fowls, and lay down some rules as a guide to exhibitors.—FIDELIS.

[It may be that some of the Judges who undertake to award prizes to Game classes know the private marks of some of the exhibitors; but all are not marked alike, and the inspection of a book or list would show some marked to the right, some to the left, some in one place or way, some in another. Other fowls are not so marked, and we do not at all think marks are ever looked for—we are sure they are not by our oldest Judges. You are wrong in saying that Judges "allow these marks to have much influence over them in giving their decisions." Such a remark should not be written unless it can be proved. Even Judges cannot agree about the points of birds, by your own admission; how, then, can they be called upon to draw up rules? It is generally supposed scanty, firm, and close plumage is preferable to long and necessarily loose feathers in a Game cock. We only give our own opinion.

Under the awards of some of our old Judges, poultry showing has become what it is, and their awards, as a whole, have been almost unquestioned. They have certainly been approved. We have the pleasure to know most of these gentlemen. They have told us frequently that they are quite ready at any time to retire in favour of younger or more able persons than themselves; but that if they officiate, it must be on their own terms.]

DUBBING GAME COCKS.

As one interested in the solution of the question, let me ask Why is the dubbing of Game cockerels to continue imperative? Why should good dubbing be essential with Game, while to tamper with the head disqualifies with Spanish? Surely it is admitting more mechanical dexterity as an aid to excellence in competition. In my own case, I have a yard full of Game chickens, but I never dubbed one, and know no one in my neighbourhood who can. Personally—I confess to the depraved taste—I prefer the look of a well-dubbed bird. Probably, years ago, I should have admired the spigot tail, cropped ear, and hogged mane of the "neat cob." I like with "GALLUS PUGNAX," but feel and judge (partially) with "HUMANITAS." With deference to the former I must think that scalping brings more than a very little pain to all bipeds.

Give us liberty. Our birds are not candidates for the mat and the silver spur. If readiness for the pit is to be the criterion of excellence, then let them be shown, not only dubbed and in condition, but with the squared tail and trimmed wing.

Give breeders the liberty allowed this last summer at the Crystal Palace for birds of all ages. Do not let the Judges' fiat be distanced when a good bird comes home in front, carrying comb and wattles extra.—DUCKWING.

REARING CHICKENS WITHOUT A HEN.

I HAVE very often noticed letters from many of your correspondents begging to be informed how to rear young chickens without the hen's assistance. I have dabbled in this to a great extent myself, both as to young birds and chickens; and though it is not quite the proper time of year for chickens to be most about, it is, perhaps, the more likely that one or two of a stray choice breed should demand extra care.

There are three great points to consider—How to make the young chicks eat, How to keep them warm enough, and How to keep them through the increasing hours of darkness.

For the first—How to make them eat. I always observed in feeding young birds in nests that if one held the bread and milk too close to the nest they never thought of taking it—holding it overhead as the birds do they snapped it up directly. Now, in watching a hen with her chicks, we find she always scratches the ground at their feet, and when she feeds the brood she picks up grains and holds them under their bills. So I go now on that line—chickens that will not peck are always brought to me, and I throw the crumbs about with a bit of stick, and keep touching the chickens underneath the bill, and stroking down their throats outside, sometimes fill their naturally look down after the stick, or finger, and see the food and eat it. They stuff sometimes till their crops stick out in the most ridiculous way, just like large walnuts.

Crumbs of bread do almost best, I think, to feed them with,

and grains of rice; but my chicks will not eat rice unless it is boiled quite properly in the Indian fashion, as if it was for a curry. They also have potatoes and barleymeal, or little scraps of fresh meat. The how to keep them warm enough is partly involved in the next step. We never let them get cold. The moment the meal is over they go into a punnet filled daily with nice soft moss, and this basket is entirely wrapped up in a large piece of batze or flannel, and once or twice, to my great amusement, we had to give them a bottle of hot water to keep their little feet warm. The basket then was put to rest up against the bottle. We always place something rather solid on the top of the basket to keep down the chickens, which like to feel covered up. For a long time a big duckling sat there every night; but now he is grown up and has long ago changed his quarters, as have the chickens theirs; but anything heavy does to press them down. We invariably put the chicks to bed the moment they have done eating, except for two or three hours in the day, when they run about in a large cage standing in the sun.

The keeping them through the night is very simply done, as it is chiefly want of food that makes them feel the cold. We give them a good supper just about ten o'clock; they can then wait tolerably till seven the next morning, though the earlier and later they can be fed the better.

Treating them thus they get most absurdly tame, will not acknowledge a hen by any means when we have sometimes tried, but come scuttling back to their own proper friends. This spring there was some plague with a hen having eggs given her some later than the others, and the ten little chicks, of which I was taking care, used to come rushing up my sleeves and close to my face, and then screw themselves in and make the peculiar purr that pleased chickens do make.

A duckling and chicken were again the only produce of a far-brought set of eggs; the duck took to the chickens and I took to the duck; and, when duck had a soup-plate full of water, he would insist on taking chick with him, and, like a meek little girl with a naughty big brother, little Miss chicky went.

Some of those home-reared chickens are now very fine, they are some weeks in advance of others hatched before them, and brought up by a hen.—E. M.

OFFENSIVE FLAVOUR IN THE FLESH OF FOWLS.

I SEE in last week's Journal "AN OLD SUBSCRIBER" complaining of offensive smell with fowls. Mine were in the state as he mentions, and I was some time before I could find out the cause, the eggs being so bad we could not eat them. At last I found by steaming some of each of their food, the odour arose from the grain given them, which I had been having from Mark Lane, which is gatherings of all kinds of grain mixed. Since purchasing the grain separately—viz., to one bushel of barley mix one peck of good sweet oats, and half a peck of Indian corn, I have never found the slightest trace of it. The roosting-houses smell in the same manner as the eggs tasted, although they are cleaned out two and three times each week.—T. B.

A QUEENLESS HIVE.

ON August 12th, 1861, I wrote to you detailing a result of introducing a Ligurian queen to common bees up to that date. On August 26th, saw first young Ligurian bees, just five weeks after introduction of queen, being a week longer than seems to be generally the case.

All went on right till September 5th, when, as subsequent events have proved, the queen was lost. On going to the bees on this date I saw the queen at the mouth of the hive. She immediately attempted to fly, but apparently owing to her great weight she was unable to do so, for she fell to the ground. She again made another attempt and flew about three-quarters of a yard and got amongst some lupins. Here I saw her very distinctly, looked at her very attentively, and attempted to get her to crawl upon a leaf I put to her; but instead of going on the leaf she again attempted to fly, and seemed to get to some raspberry bushes, when I lost sight of her, and could not find any traces of her though I examined the place very attentively.

I regret now that I did not seize the queen whilst on the lupin with my fingers, and place her again in the hive, but at the time I was not sure she was the Ligurian queen, as I could not see

any orange bands round her body. I thought it possible it might be the queen from the old stock of black bees which had got to the site she (the black queen), originally occupied, as the old stock is only 200 yards or 300 yards off, within an easy distance.

The queen was much the finest one I ever saw, the wings did not seem to cover more (if so much), than half her body; hence her inability to fly. This queen must have gone much darker since I received her, as the orange on her body was then quite visible. I also watched the hive for a considerable time to see if the queen returned, or if any commotion would take place. Neither the one nor the other, as far as I was able to determine, did take place; and as I had always been led to expect that a commotion among the bees would take place as soon as the queen was missed, I was led to think, that possibly the queen might have returned, or else that the queen belonged to the black hive, and so that all was right. To-day, after an absence from home for about a week, I went to the bees and was astonished to find no fewer than six dead queens on the ground in front of the hive, proving, as I think, that the queen was lost on September 5th, and that the bees have been rearing artificial ones. The above confirms what the "DEVONSHIRE BEE-KEEPER" says in this Journal, that it is not always the case that excitement takes place in the hive when the queen is lost.

The advice I want is, what to do in this case, as I do not wish to lose the stock. From the article in this Journal, and from previous remarks made by the "DEVONSHIRE BEE-KEEPER," he seems convinced that the queen can lay eggs though unimpregnated, but that all the produce will be drones. Now, has it been shown, or does the "DEVONSHIRE BEE-KEEPER" know, whether after drones are produced that these drones will have intercourse with the queen, their mother, and so render her capable of laying female eggs? If so, there is a reason for her laying drone eggs, or rather we may consider it a wise provision of Nature to prevent the hive dying out. Should I let the bees alone and watch the result? Should I unite them to another stock, or should I introduce another Ligurian queen to them, provided the "DEVONSHIRE BEE-KEEPER" could furnish me with one?

It would be interesting to leave the bees alone and see if the queen would ultimately lay female eggs, only the season is so far advanced and the hive is not very strong—both against the experiment; however, I wait your advice.—A.

[The queen, doubtless, missed her footing on the combs (which I fancy were not worked nearly down to the floor-board), and not finding her way up very readily quitted the hive and was lost. Had you seized her at once and returned her to the hive through an opening at the top, all would have been right. If no drones are left either in your own or any neighbouring apiary, the young queen must remain unimpregnated, and in this case will breed drones only. She will certainly not be impregnated by her own offspring. If you leave things as they are you may (in the absence of drones), have an opportunity of testing the doctrine of parthenogenesis; but the stock will, of course, be valueless if the queen remain unimpregnated.—A DEVONSHIRE BEE-KEEPER.]

REMOVING BEES A GREAT DISTANCE— MAKING A SWARM SETTLE.

I AM about to change my residence, and have four hives of bees that are pretty strong. What would be the best way to move them? The distance is about eighty miles.

To make a swarm settle I take a looking-glass, and throw a few flashes of lightning, as we said when children, among them. The bees settle at once.—IRELAND.

[The hives should be tied up in cloths of an open texture (cheese-cloth is the best), inverted, and kept as steady as possible. With these precautions they may be removed with perfect safety.]

GARDEN WARBLERS AND NIGHTINGALES IN CAGES.

I HAVE just procured a couple of Garden Warblers, wishing to keep them on account of their beautiful song. On referring to the instructions of Bechstein I find that on account of the quantity of food of a farinaceous nature (German paste) which they consume they do not live long in cages. Do you think that if I give them a great deal of raw meat and fruit, instead of the usual diet, I shall succeed in keeping them in health? Also, as I keep the birds entirely for their song, whether they sing equally

well if I put half a dozen birds together. For instance: the two above named, one Nightingale, one Blackcap, one Redstart, and one Whitethroat? The size of my largest cage is 3 feet high, 2 feet deep, and 6 feet long. At present my birds are in the ordinary cages, rather less than a foot square.

It may be of service to some of your readers who keep soft-meat birds to inform them that I have kept Nightingales in full song, also Robins, throughout the winter as follows:—During August and September I collect all the caterpillars and maggots from rose trees and cabbages, putting them in a large, covered jar, with a little fresh earth and leaves of either lettuce or cabbage. They continue growing, and eventually change to the chrysalis state, which they retain all the winter. My birds enjoy them exceedingly in either form at the rate of two per day each bird.—AVIARY.

[My father says Garden Warblers are not likely to sing if kept together, and that each should have a separate cage. German paste he considers too heating, and a bad food. He thinks the nuts of a bullock's liver boiled hard and grated, and mixed with yolk of egg, bread crumbs, and crushed hempseed, with occasionally a little raw meat, the best artificial food.—B. P. E.]

THE AILANTHUS SILKWORM.

I AM just now much interested in the growing of silk. I have been in communication with a lady in the south of England, who has been engaged for years in cultivating the finest Mulberry silk. I have just been reading a short article on the subject of silk in your Journal of August 27th, in which Lady Dorothy Nevill assures you of her success. I am anxious to know (since she uses Ailanthus instead of Mulberry, and the coarser worm instead of the white) to what extent she has carried the experiment? What number of worms? What proportion of labour required? Proportion of silk to number of cocoons, and the worth of the silk? These, I conceive, are only lawful questions to ask, and ready as I should be to enter upon the labours of a silk plantation, I should not like to do so without I had some data to go upon; and where is Dangstein, Lady Nevill's residence? Is it in Germany? I feel quite sure that there is sufficient reason to expect silk may be successfully cultivated in England, and if I could obtain through your valuable paper the requisite information, I should be delighted. Two more questions—What species of Ailanthus is it? and if the copes of trees are used, do not the birds devour them?—FRED. W. TOWLE.

[It is quite a different worm from the Mulberry one; it feeds entirely on the ailanthus tree, a most hardy shrub (a kind of ash), which may be grown as our beech copse woods are here—that is, if cut down, they shoot again from the stems. Lady Dorothy Nevill's worms were, after having been hatched a week, placed on the trees, where they were left till they made their cocoons. The second crop of worms were hatched too late, and Lady Nevill was away from home during three fine days, and the wasps having no fruit to get at devoured them all. Not having been pestered with wasps before, Lady Nevill did not guard against this, which another year she will do. Mr. Towle had better wait till Lady Nevill's pamphlet is published, as then there will be very few; it, where the eggs are to be obtained, &c., and there is nothing can be done till the spring. Dangstein is six miles from Petersfield station on the Portsmouth direct line.]

OUR LETTER BOX.

JUDGES AT SHOWS (*A Rabbitancier*).—The Judge who acknowledged that "he had not been particular in his measurement" of the ears of Rabbits shown in the class for length of ears, certainly was guilty of a dereliction of duty, but we cannot insert anonymous communications. The Show in question is under a cloud; and if many more complaints are published about it, its next year's prospects will not be very encouraging.

KEEPING PIGEONS' EGGS (*M. R.*).—If the eggs of Pigeons are removed before being set up in and carefully kept, they will remain good for hatching for about a month.—B. P. E.

LIGURIAN QUEENS (*W. Books*).—I regret to say that I am very much in arrears with regard to the supply of Ligurian queens. Had I been aware that it would have turned out so troublesome and unsatisfactory an affair, I should never have attempted to supply queens, but should have confined my attention to the propagation of stocks, which I find will travel safely to any distance, and are free from the uncertainty and frequent disappointment which attend the introduction of queens. If a queen arrives safely at her journey's end, I consider my responsibility ends also.—A DEVONSHIRE BEE-KEEPER.

AILANTHUS SILKWORM (*J. Lady*).—You had better wait for a few weeks. Lady Dorothy Nevill is about to publish a pamphlet, which will give you all the information you need.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 63° and 45° respectively. The greatest heat, 74°, occurred on the 8th in 1859; and the lowest cold, 36°, on the 11th in 1855. During the period 114 days were fine, and on 124 rain fell.

A FEW DAYS IN IRELAND.—No. 1.

ONG have been convinced that in this country justice is not done to the gardening and gardeners of Ireland—in fact, inquire wherever we might, or from whoever we hoped to gain information on these topics, we were invariably disappointed. Little could be gathered—and what

was gathered was crude. So we resolved to send thither "OUR SPECIAL COMMISSIONER," and the following is the first of a series of details of the results of his visit. We rejoice to find that his observations fully confirm our anticipations, and to learn the fact that now the third of the Island Graces has her drapery arranged as tastefully as that of her two sisters. This is as it should be; for, changing our simile, every man among us must feel that our national cable's greatest strength is to be attained, and its working rendered most easy, only by having its three strands perfectly equal.

Mr. Fish has used his critic eye and critic pen acutely and faithfully—but there is no wormwood in his ink.—EDS. J. OF H.]

SEVERAL circumstances rendered it desirable that some idea should be formed and expressed of the state of horticulture in its various branches in the Emerald Isle. Among these circumstances was an opinion that it would afford something like a test by which we might judge of the social progress and mental refinement of the great masses of the people. In this our first attempt to realise that opinion we made Dublin a sort of centre; and as our time was very limited, what we may have to say of the places visited must be looked upon as merely hurried glances rather than as anything worthy of the name of descriptions. Any deductions which we may afterwards draw from such a hurried visit must be looked upon as being a general rather than any particular application. If we attempt criticism at all, even in matters of taste, it will be done in the most kindly spirit, feeling that if we can give no pleasure we have little right and less inclination to inflict pain, and more especially since from all we came in contact with we received the greatest kindness, courtesy, and willingness to oblige.

Before noticing any places, it may be as well, in the way of introduction, to dispel at once two ideas, which, though ignored by the well-informed, are yet found lurking in the minds of many in this larger island—namely, that the Irish are even now only slowly emerging from a state of comparative barbarism; and, again, that so far behind are they in general industry, in gardening, and in agriculture, that any poor wight who would or could use neither his brains nor his hands at home, might yet manage to pick up a livelihood among the still lazier and more indolent natives of Ireland.

That this last idea no greater error can exist; and we shall see our canny friends of the spade and the plough some service if

we tell them, once for all, that they had better keep Ireland out of their thoughts, unless determined to take active, intelligent heads and active hands and feet with them there.

Laziness might have been too much of a national trait when the few pennies a-day, and these procured with difficulty, constituted the sole motives for activity. There is no resisting the fact that a man must eat and live comfortably before he can work energetically. Sad and disastrous times have been endured by our Irish brethren, the bare recollection of which saddens and darkens the spirit. But the angel of want and of woe, as he passed through the land, scattered from his wings the seeds of future progression and prosperity. Government aid, state help, in the shape of loans for effecting permanent improvements; above all, Christian benevolence, rising superior to all petty sectarianism, and the self-sacrificing patriotism of the old resident proprietors of the soil, who in the most unfortunate times never lost faith in the future destinies of their country—tragic noblemen these, whose deeds and whose efforts have made for themselves shrines in the hearts of a people;—these, combined with assistance to willing emigrants, and the land coming into the possession of owners who had capital to work it, instead of absentee possessors, who took all and gave, or could give, nothing in return, along with other causes too numerous to mention, have given an impetus to exertion and labour, and showed that Irishmen, so active and industrious in other lands, could be equally energetic at home when sufficient motives could be presented for that industry. And now in the activity displayed in the docks and quays of Dublin; in the railroad pace with which the cars rattle along the streets; in the excellent management of the railways; in the bustle in the warehouses and marts of business; in the ability with which machinery is managed on improved farm homesteads; in the zest with which the long-handled spade or shovel, and the short-handled steel forks, are used in garden and field; in the neat whitewashed cottages taking the place of the chimneyless and windowless mud hovel, we not only see everywhere indubitable signs of active go-a-headism, but strong reasons for believing that anything like laziness and sloth will ere long be unable to find any elbow or standing room there.

Notwithstanding, however, these signs of progress, the wages of labour in some districts are still too low to permit the full development of human muscular labour power. On this account some of the best friends of Ireland would be sorry if the number of returning emigrants to Ireland should be greatly increased. Perhaps just now it would be as well if these emigrants continued in the land of their adoption. But the tendency of all improvement is so to increase labour, that we have no doubt but that ere long much more labour power will be wanted than can now be obtained, and then wages will rise to the benefit alike of the employer and the employed. There seems, from all we have been told, a principle at work in Ireland which will tend to make wages more uniform than they are likely to be for some time in England. Not only is it the most energetic among the Irish, as it is among the Scotch and English, that emigrate to distant lands; but whilst in England the stayers at home can hardly be induced to leave the sound of their parish church bells, there is little of the same feeling among the resident Irish, provided they can still locate themselves within the precincts of the sacred isle.

There is a little sorness mingled with a good deal of fun and sarcastic irony among our Irish friends, as they quiz you respecting the opinions still held of them by the good people of Great Britain. "Well, Mr. F., do you really find us as great barbarians as you were led to believe?" "What! really ventured among us Paddyites, without being ball and cudgel

proof?" "Don't you find us woefully behind your clever John Bullites?" "Ain't we thoroughly sunk in wretchedness and misery?" "Haven't you found a poor tattered beggar at every turn?" &c. Well, our hearts are glad that our good neighbours can poke their rollicking satire and dry humour at us. We will take it all and look for more, if it only makes them happier, and gives them more resolution not to be satisfied until they far out-strip us in improvement.

We forget whether it was Leigh Hunt or Charles Lamb that, after passing one of the wretched mendicants sitting in the streets of Dublin, his heart smote him, and returning to the man he said, upbraidingly, "If you are really in want, why don't you beg?" "Ain't it begging I am?" said the poor wretch, as every shake and movement of his rags showed the shrivelled and famine-struck skin. Now, no such sight did we witness in Ireland. Only three times were we asked for alms. Had we gone to an equal extent through the streets and lanes of London, Edinburgh, or Glasgow, we should have expected to be applied to much oftener, and to see more filth and wretchedness too. Not but that among the females some dresses were seen that might form a pattern for some new style of scolloping and fringing: not but that among the males coats might be found of divers colours, and openings to let in the wholesome air, where no piece of suitable colour could be found to fill it; but these were merely such exceptions as seemed destined ere long to become curiosities.

Mud huts and chimneyless huts do, no doubt, still abound in Ireland. We were privileged to see only one, some eighty miles from Dublin, and that close to a miserable drink shop, that seemed never to have known the smell of lime inside or out. These mud huts with just such a patch of ground as a family might possibly exist upon, but more likely starve upon, were a fruitful cause of misery. Owing to the strange and complicated modes of tenure of land, the most benevolent landlords would have been next to powerless in breaking up a system which was sapping the life blood of the nation. The famine and the emigration to which it led did much to break up the system—did more than any reasoning could have accomplished. Many who starved upon their plots are now, not small farmers, but well-to-do labourers, living in pretty cottages, with an allotment of an eighth or even more of an acre—sufficient to employ them in their overtime, with convenience for keeping a pig, and also in many cases a cow, if they choose to hire enough of grass land for the purpose. Many of these men from their saving habits will ultimately become *bona fide* small farmers. The more such a system has been adopted, the more we see the marks of improvement. It was quite pleasant to see the clusters of cottages so clean whitewashed inside and outside, and going before the English, and Scotch too, in a matter of science, by washing the roofs when consisting of tiles or slate, and thus making their houses warmer in winter and cooler in summer.

Though our view was limited, we do not speak altogether without book. In one day we passed through Bray twice, where a fair was being held. There were a number of cows and oxen, a greater number of sheep, and perhaps still more of pigs, many of which seemed on friendly terms with their owners, as they held them in something like submission by a straw rope round the legs. The pups of all sizes, even when each pig seemed to belong to a separate owner, appeared to be in good condition; and about their owners there was no mistake as to the appearance of well-to-doism. On returning we met with many cars, the riders in which were just cheerful and happy, and ready to vent their good humour on all they met. The streets, though full, had every trace of good order as well as good fellowship. We saw nothing at all out of the way except a pretty girl dancing in the street, with a circle of very quiet well-behaved people around her; but whether she was learning them some new step or was merely giving vent to the exuberance of her spirits we could not learn. In expressing our approbation of the general respectability, we were told to wait until it was late and then we would see. Well, we did not wait, and therefore can say nothing as to the correctness of the prophet of evil.

A few days later at Kilkenny the streets were crowded with cars, and the cars themselves crowded with riders to see some races a few miles distant. Only a very few were seen in the streets whose garments had anything of the tattered or torn; and many an old lady, and young damsel too, looked extra respectable, as they surveyed the scene dressed in their fine blue cloth cloaks with a hood, which they pulled over their nice braided hair instead of a bonnet or a pork-pie hat. There were

figures and faces there which many a painter would have been delighted to transfer to his canvass. But if the bulk should approach in character to the little we have seen, then, to all those who delight in rags and wretchedness, and who consider that the highest branch of art consists in depicting the extremes of human agony and woe, we would say, "If you think of going to Ireland at all you must go quickly, for all such specimens will soon be numbered with the curiosities of the past."

One simple fact, like the feather thrown into the air, will often give a good idea of the state of a country. The first morning we were in Dublin we got up early and had a ramble before breakfast, map in hand, looking at some of the finest churches and chapels, the Custom-house, the docks and splendid quays, furnishing an example to proud London: the College, Bank, St. Stephens and other Greens, Merriion Square, and the house in which the great O'Connell lived there; and as we had listened to his burly eloquence in London we bent our steps to Conciliation Hall, the scene of some of his greatest and most successful efforts—and lo and behold! it was crammed to the wide doorway with sacks of flour! Many and different opinions may yet be held as respects the power and genius of O'Connell. Few will now deny that to wrongs and injustice he owed the power which he wielded. Oppression in every case ever brings with it a double curse—a curse to the oppressed, a curse ultimately but surely to the oppressor. Some would even now stir up the expiring embers of ill-feeling: better smother them in flour-bags, sing a requiem over the past, and let bygones be bygones. Britain has shown that she will treat Ireland as a loving sister, anxious that she should be happy, prosperous, free, independent as herself; and Ireland, ever generous and kind, will not decline the mutual embrace. One thing we are certain of—and that is, that when a people have plenty of flour-bags, plenty of pork, beef, and mutton, they are neither likely to lag behind in the march of improvement nor be greatly influenced by the oratory of the political agitator. Good dinners go a long way to make quiet, contented, comfortable citizens. Good dinners will yet play a great game in Ireland.

Let us forget the subject, we must say in conclusion, that we were disappointed in not meeting with a sign which we associate here with social and moral refinement. We saw nothing worthy of the name of window gardening. Even most of the squares in Dublin, so far as flowers and any pleasure from the grass to the surrounding inhabitants are concerned, seemed to be kept entirely for the benefit of some neighbouring dairyman. The utter lack of window plants was a great loss to us in our wandering, as we have got into a habit of forming an idea of what sort of people live inside of a house from noticing the plants outside, and we seldom make a mistake in this matter. However, we had no means of thus musing in Dublin. Some told us that it was against the civil regulations to have plants outside of windows, as they might be dangerous; but that could be easily prevented, and there were plenty of balconies from whence no plant could fall. Others said that many had little gardens out of town, and, therefore, did not trouble themselves with them in their windows in Dublin. Be these reasons as they may, the want of such plants was depressing. We do not say that it exactly savours of want of refinement, for until lately there was but little of window plants seen either in Edinburgh or Glasgow. We do not know how such northern friends would like it if told that notwithstanding their hardheadedness, shrewdness, and intellect, they were something behind their southern brethren in refinement. Our Dublin friends will delight us if they improve also in this respect. We went through miles of streets and squares without seeing a single plant in a window. Amid such a wilderness of brick and stone, we landed at last on a charming oasis in the shape of a beautiful blue china basket or box, just the size of the window-sill, and filled to overflowing with fine, healthy, blooming Scarlet Geraniums. This was in Clare Street, close to Merriion Square. We have no right to make public the name on the door of the house, but if man or woman had come out we must have thanked them for the treat. Some more impetuous, like the girl at Bray, might have tripped the Highland Fling on the pavement. At all events, we hope such a beautiful box will not long remain "alone in its glory." R. FISH.

A VARIEGATED OAK.—A common Oak tree growing near Mawley, the seat of Sir Edward Blount, containing upwards of 30 feet of lumber, was struck on the 26th of June, 1838, by lightning, during a severe thunderstorm which passed over that

part of the country. The tree did not appear to have suffered at the time, but shortly afterwards the foliage, which was previously green, as in other trees of the same species, became beautifully variegated, and has continued ever since to produce variegated leaves, and otherwise to maintain quite a healthy appearance.—(*Scottish Farmer.*)

KEEPING BEDDING GERANIUMS OVER THE WINTER.

This is the most pressing question in October to thousands, if not to the million. The sweeping out of the last severe winter was like that of a new broom, and nothing in the way of plants was left to thousands but to begin a fresh start in the spring. I was among the sufferers, and I must turn over a new leaf this winter.

Let us suppose that this will be the mildest winter we have had for the last twenty years, and suppose that some of us would believe the weather prophets if they told us the prediction, and let things go in the old tracts, and then suppose the ensuing winter, after Christmas, would be even more severe than the last, how should we get out of the fix? It is foolish to trust to the weather at any time in matters horticultural, and in the winter keeping of plants more than in any other point the year round.

I shall begin at home, and say how I mean to keep two or three thousand Geraniums after all my under-glass room is filled up with things which would not rest or keep dry for ten days together. The oldest plan of keeping Scarlet Geraniums in winter in a dry state is still one of the best ways of doing them, and I shall put up four or five hundred plants that way. My cellar is as dry as a bone, as the saying is, but it is rather too warm; I mean to give it more ventilation to make it cooler in the first start. 45° was the regular heat of the cellar in the coldest of last winter, and that was exactly the degree while there was no frost at all. Now I want to keep the heat for my keeping Geraniums down below 40°, or say 40° itself; for with all our knowledge there is not a man or woman in the three kingdoms who is yet certain of the best degree of heat or cold of the place where Geraniums keep best in long winters. The best degree for keeping Potatoes is 32°, just the freezing-point, and if Potatoes could be kept at that temperature the whole of the winter and to planting-time in the spring, they would never sprout indoors or wherever they were. But I must assume the best degree for keeping Scarlet Geraniums, and shall say 35° to be the very best till experience proves a better point on the scale. I am quite confident that the right degree of heat is the grand secret for keeping Geraniums in a dry or half-dry state in winter; also that the heat should be as even as possible the whole time, and not rise and fall with the changes out of doors: therefore a cellar, which is perfectly dry, is a far better place to put them in than a room above stairs in any part of a house. Unless the place is perfectly dry it is next to useless trying to keep Geraniums there.

Then, the oldest plan is this—A man was ordered all at once at the end of October to spend the winter in Italy. It was a mild autumn, and his beds were not then touched by the frost; but he must be off that afternoon, or else lose the chance of getting off for a month—the worst in the year for his chest. He ordered his best Geraniums to be taken up “as they were” on the instant, that he might see them in-doors before he left. They were soon up, and they had them bunched as they bunch Coleworts for the markets—that is, three, four, or six, or so many, according to their size; were tied together; the ties just over the roots or round the necks of the plants, and each bunch was hung up on a nail against the passage going into one cellar from another. Every leaf was left on, and some of the mould to the roots on account of the hurry. Some one was told to look after them, and pluck off the leaves when they dried up, but he forgot all about them till very late in March, and every one of the plants was then alive, smothered in a dry dusty covering of old leaves, and sprouting below this covering in all directions. I had the story from the clergyman of this district—for we are not parish people here in Sarbiton—and it must be true; but then that cellar was as dry as mine is. I could keep ten thousand Geraniums safe as nuts in my cellars, for I have more than one, if they would stay or stop with me; but that is my difficulty. They will not stop with me in the cellar; they are on the go as soon as I put them there; they will not stop and I cannot keep them. That shows

the place ought to be as cool as I say—35°, or at all events under 40°. I can conceive a case in which leaving the whole of the leaves on the plants till they withered would be of great advantage—say a bed of strong succulent plants. The leaves in a dark dry cellar would gradually suck all the extra sap out of the succulent stems, and leave them in a medium state between soft and hardwooded—just the right condition supposing the place was not over 35° of heat the whole winter; but if it was much warmer and currents of air allowed through it, the dryness from the sucking of the leaves and the parchiness of the air in motion, would dry up the whole of the plants to cinder substance.

Then, three conditions are absolutely necessary to render it safe to put up Geraniums with all their leaves. The first, a uniform temperature of 35°, supposing that to be the right point; the second, perfect exemption from all damp; and thirdly, a still atmosphere. Secure these three points, and your Geraniums may be pulled up out of the beds and be hung up in the place the same day.

The best way I ever found to keep Geraniums, however, was to cut off every leaf of every one of them, and to leave them their entire length, and I have begun on the first day of October to prepare my minims or smallest kinds that way, such as Harkaway, Baron Uugel, Crimson Minium, Golden Chain, and a dozen more kinds of the same stamps and habits that have not yet been named. Whether these be in pots or in the open ground I do them all exactly alike, and I shall not lose one out of five hundred of them; and all Geraniums that are bigger than mine would, of course, keep much more easily. Let me take one kind, the most difficult of them all, the Golden Chain, and say I had 500 of them back from the Experimental, which I had not by the way, and that 300 of them were planted out all the summer, and 200 being very small bits of plants, were kept in pots till the first of October. I shook them out of all the pots and up with those in the open ground, and did not leave a single leaf on any of them, nor a bract. The little blades which fold over the buds of Geraniums before they come out into leaves are called bracts; but no wound or cut was made in the shoot, so that there should be no wounds to fester with damp or cold. These I planted in very light loose soil in shallow boxes well drained, and the whole will be kept half dry and as cool and dark as I can to the end of January. By that time a few top leaves will be made, and I must bring them to the light.

The next degree of plants will be of the strength of Tom Thumb, or thereabouts. They also will be kept in separate boxes after being stripped of their leaves. I shall have them in the dark, but not quite dry at the roots. They will need to be watered once in six weeks or so, and next day after the watering the surface of the soil will be loosened, and a thin covering of soil, as dry as dust, will be sprinkled over the whole surface to keep down the damp from the last watering.

All my Variegated Geraniums will be thus wintered, except one lot of seedlings, for which I must find light, and room, and warmth as best I may. Punch, and all of the strength of Punch, after the leaves are clean cleared off them, will be planted in by the heels on the floor of the cellar at one end, and as there must be a large bed of mould 4 inches or 5 inches deep, they will need no watering hardly; their own substance will keep them fresh enough till they begin to sprout in the spring, when the real battle begins. Now what I would recommend when there are only a dozen of plants and all in pots, or some in pots and some in boxes or baskets, or in a bed, would be this—never to attempt to keep a Geranium dry in the pot if it was growing in the season before unless the plant is over three years old, and the pot is a No. 16. They would keep as safe in the pots as out of them, and more safe in some places; but in the spring you cannot moisten the old balls without giving them ten times more water than they ought to have. All the young fibres will then be dead in the balls, just like the annual roots in Mr. Rivers' orchard-house trees, and the young fibres will not take readily to old balls, or to balls too wet or too dry, and no mortal can have the balls in exactly the right state.

This brings us down to the roots. I shorten all the roots of all my Geraniums, those of the Golden Chain as much in proportion as those of Punch; and all the very small fibres I cut right off in October—a quicker way than allowing them to die by inches. When an Apple, or a Peach, a Rose, or an Oak, or a sapling, or a Golden Chain Geranium, or all Geraniums, have their youngest roots, cut off as early as October, the very first

thing the oldest and remaining shoots will do will be to break out into small white points of roots all over their surface if they are put in warm moist soil; and, what is very, very singular, this new rooting will come faster if all the leaves of the plant have been cut off at the time the roots were trimmed. But you can prove that yourself just now with any two plants in the garden, two young Laurels will do, two Clematis, two Gooseberries, or two of any kind; up with the pair and pare their roots; off with all the leaves of No. 1, but No. 2 must leave them on; but No. 1 will have made as many young roots in one month as No. 2 will make in double that time, so that the presence of leaves does not always, and under all conditions, hurry on the making of roots.

It has only been since I had to do things of this kind at my own expense that I began to understand the value of one process over another which might be very like it, and Cobbett's definition of economy is my only rule. According to him good management means economy, and no saving of time or money ever was or ever will be real economy in the absence of good management. Well, to winter a lot of budding Geraniums, or these, or any other plant seems easy enough, and so it is; but it is the want of economy of good management through the winter which tells so sadly against people in the spring. They never look at them for months, and some forget them altogether, like the man who left the leaves on all the winter. I look over my plants through custom, and if I should be ten days without seeing them I should think they were all dead. It is true I do very little to them many a time I see them; but it is equally true that they never want but very little doing to them when it is done so often, and with such care as practice suggests at first sight. If I see a spot, or a speck, or a bit of mouldiness, or a very dry corner, or a damp-like place in the bed, I rectify it on the instant. There are fifty little things which want doing, and which one could never remember two days together; but every one of them is sure to meet the eye in a long winter with a large lot of plants in a dry store.

To sum up in one paragraph, all Geraniums for dry housing to have all their leaves cut clean off, and all their small roots in October, and, if the tops are to be touched, to have all the green soft parts cut away, to shake them out of all the old balls, and to pot, or box, or bed the roots in shallow, light, sandy soil, and not to let them get quite dry.

D. BEATON.

THE ROSES OF 1860.

ALL who have frequented the exhibitions this year where Roses have been shown have seen (and many of them borne witness to it) that never was there a season in which their favourite flower came so untrue to character. This has taken place not merely with those of recent introduction, but also with old and long-established claimants to popular favour; many it was hardly possible to recognise, and the thought was not seldom entertained the grower has lost his tally, and does not know what to put on them, and so puts the nearest he can. This, however, was not the case; the fault lay entirely with the unpropitious season.

It may, therefore, seem (and in fact is) somewhat difficult to decide safely on the character of new Roses; and I hold it to be a matter almost of impossibility to decide on them the first year of their culture here, they are so lucked and hemmed about, their constitution is so tried for the purpose of increase, they are so heated and drawn, that a flower must have very superior qualities that suggests to growers, "this is a topper." I shall, therefore, only now speak of those which came out in the autumn of 1859, and are popularly known as the Roses of 1860.

If we have to complain of raisers here that they carry their plan to excess of pushing new flowers forward whether they have merit or not, we may at any rate say that our friends on the other side of the Channel are not less to blame in this respect. About forty Roses were announced as coming out in the year 1859-60. Many of them will never more be heard of; but I think, with all deductions, I may confidently say that no season has ever produced such a number of really good flowers as that did. The season of 1861, so far as one may judge (producing forty Roses), is by no means equal to it, and certainly no season previous was so prolific in good flowers. Those whose merits were so small as not likely to give them a permanent place in our rosarium were numerous. And there is one point in which the really good Roses of that year were remarkable—viz., habit,

This is a point that ought to be well attended to. We have flowers of all hues, and shades, and tints, such at least as are possible in a Rose; but we want now good robust habit—such, for instance, as *Engène Appert* and *Madame C. Craplet*. Again, I think our lively neighbours should be reminded that we do not now want any "ragged Jacks," or large coarse flowers; they may be "useful" for a show, but I do hope that soon the better taste of the public will compel judges to regard such flowers as *Souvenir de la Reine de l'Angleterre* and *Anna de Deisbach* as materially damaging the chance of a stand. Let us aim at size by all means, but do not let us sacrifice refinement to it. No one can, I think, deny the superiority of a large handsome Rose to one of smaller calibre; but if the former has great coarse petals, and the latter well imbricated ones, or nearly cupped, the smaller one will be the favourite. The exquisite shape of *Prince Léon*, or *Coup d'Hôtel*, or *Gloire de Santeny* is what should be aimed at; and if I have an opportunity (as I hope to) of chatting to our friends the French raisers, I shall not fail to press this matter very strongly.

Those flowers whose rejection is tolerably certain are *Duchesse de Magenta*, *Gourdanet*, *Isoline*, *Madame Eugénie Verdier*, *Madame Pauline Villot*, *Mademoiselle Eugénie Verdier*, *Mademoiselle Marie Dauvencé*, *Montebello*, *Triomphe de Bagatelle*, *Vainqueur de Solferino*, and *Victoire de Magenta* among the Hybrid Perpetuals; *Cesonie*, *Madame Hoche*, *Mosses*; and *Guiditta* and *Guillaume Tell*, Bourbons. Those whose position is somewhat doubtful are *Alexandrine Belfroy*, *Admiral Nelson*, *Buffon*, *Cocquette de Lyon*, *Leonie Moise*, *Princesse Imperiale*, *Clotilde*, and *Triomphe de Lyon*, Hybrid Perpetuals; and *America*, *Noisette*. Those which I have every expectation of seeing general favourites are *Belle de Bourg-la-Reine*, *Empereur de Maroc*, *Eugène Appert*, *Gloire de Santeny*, *Louis Quatorze*, *Louis Guillemo*, *Madame Boll*, *Madame Charles Craplet*, *Mademoiselle Louise Carique*, *Mademoiselle Bonnaire*, *Senateur Vaise*, and *Victor Verdier*, Hybrid Perpetuals; *Baron Gonella*, *Victor Emmanuel*, and *George Peabody*, Bourbons; *Duc de Magenta*, *Madame Blachet*, and *President*, Teas. Most of these have been exhibited this year, and some of them very finely so.

With regard to the Hybrid Perpetuals, the *décor pucheriori* must, I think, belong to *Gloire de Santeny*, said to be a seedling from *General Jacqueminot*. It is of a rich purplish-red, and approaches nearer to *Paul Ricaut* than any other Rose out. It is, therefore, of fine shape, has a thick shelly petal, and a vigorous habit, and is in fact a Rose, not without a thorn, but I do believe without a fault. Both Mr. Rivers and Mr. Radclyffe have expressed the same opinion to me relative to its merits. Next comes, I think, *Senateur Vaise*. This is also a truly magnificent Rose, apparently of the same strain, and is little behind the former flower. *Madame Charles Craplet* is a deep glossy crimson flower with great breadth of petal, but has a little too few of them. *Mademoiselle Louise Carique* is thought more highly of by my friend Mr. Radclyffe than by myself. It blooms very freely in clusters, is a very vigorous grower, but I rather fear is inclined to show a green eye, and is not equal in shape to those which I have already mentioned. *Louis Quatorze* is a Rose of brilliant velvety crimson colour, very full, but has the fault of carrying a very long footstalk, the stalk itself being rather too slender. *Engène Appert* I have frequently spoken of. Its outline is defective, but there is no Rose more striking for its brilliant colour and fine foliage, and will for many years be a favourite. *Empereur de Maroc* is a very striking Rose, admirably figured by *Andrews* in *Paul's "Rose Annual"* for 1860-61, of better habit than I believed it to be, and quite necessary for any exhibitor. *Louis Guillemo* is brilliant in colour, but I fear its petals are too few in number ever to make it a very desirable Rose; still for the present we must retain it for its brilliancy. These are the high-coloured Roses of the group, and high-coloured flowers are most generally appreciated. *Belle de Bourg-la-Reine* has flowers of a deep satin-like rose, large and tolerably full, the petals being thick and the bloom well-shaped. *Madame Boll* is a flower of the same class, of fine habit and large size. This will be a very useful flower, if it does not show the green of the eye, for exhibitors, having size and quality as well. *Victor Verdier* is an enlarged *Jules Margottin*, but not so full or well-formed as that very deservedly favourite Rose. *Mademoiselle Daumière* is the nearest approach to white we have as yet had in the Hybrid Perpetual class; and what is of great importance is a Rose of good habit (delicacy of constitution having generally marked its predecessors), for we cannot class *Madame Rivers* and *Caroline de Sausal* amongst whites. Approaching to them

in colour is *l'Elegante*, a beautiful clear flesh-coloured Rose, well-rounded petals, and of admirable growth. My friend Mr. Radclyffe thinks very highly of this flower. *Victor Emmanuel* and *George Peabody* are two fine Bourbon Roses; the latter of American origin, very free-flowering, of good size, and bright; the former very brilliant, but inclined, I fear, to the Paul Joseph style of growth. *Baron Gaellan* is a fine, vigorous-growing Bourbon, somewhat resembling Louis Odier; the flowers are whitish-rose, and the back of the petals deeper in colour. *Madame Blachet* seems to be a hardy, vigorous-growing Tea, of delicate rose colour. Lastly, *President* is a very superior flower, somewhat in the way of Adam; but more of the peculiar salmon tint of the Tea Roses is found in it than in that old favourite flower.

I have just heard from my friend Mr. Radclyffe, of Rushton, that he has written an article for the "Florist" on new Roses. Whether he and I shall agree I know not; we have had communications together about them, and I do not think that we have much difference of opinion, though as he is an exhibitor and I am not, it will probably happen that he will have the appearance of a flower in his stand in his mind's eye—I, its mere intrinsic beauty.

Nothing can be more favourable than the present fine autumnal weather for marring the wood, and I think that Rose lovers have a rich prospect before them in the year 1862.—D., *Deal*.

WINTER FLOWERS IN ROOMS.—No. 2.

THE Tulips placed last week in damp sand will not yet have shown much sign of starting. The Hyacinths (my own at least), ten days in the cellar, are getting on very well. The roots of some of them already are nearly an inch in length.

The next thing, then, is to look up the stock, and have those most advanced brought at once to the light. Most people will also wish to put in a new set to succeed the first, and it has occurred to me to adopt for all my bulbs the same plan as that advised for Tulips; it economises space, and will make a much completer dish at last. The bulbs, moreover, get a little mouldy very often in the cellar, and by this plan they have the advantage of having clean, well-aired sand.

My method is to draw each bulb gently out of its nursery-dish; and, having placed a little dry sand at the bottom of that which I wish to arrange for flowering, I hold the bulb up gently while pouring the dry sand in round it.

This plan has been often tried by myself in removing Hyacinths and Scillas, though not hitherto in entirely planting dishes. The removal does not cause the slightest injury to the roots, but the nursery-dish had better be made rather wet before the bulbs are touched.

This plan has the advantage of securing an even start; and if a bulb does fail, as it is generally shown by its not growing at all, we in this way avoid having one to replace in a set that are already twisting their roots much about. The Tulips take generally some time to start. If earliness is a great object we may try a few on a chimney-piece over a fire at night, replacing them in the dark cellar by day till the roots are well started.

The few that will be ready this week to arrange for flowering may be done as follows; for Hyacinths and Narcissi for grouping later:—Taking a number of small pots (or a range of tumblers), they may be filled with a few small pieces of charcoal for about an inch deep; then some sand; and then, the bulb being held steadily in its place, dry sand may be gently poured in all round, shaking the pot a little now and then. If the roots are long before the change is made, the bulb should be wound round, carefully avoiding injuring any of the roots; and this is done more easily by dipping them in water and then drawing them up through a half-closed hand—they go together almost like a wet bird's feathers. Few, however, will have such long-rooted bulbs for several weeks to come.

I proceed to the arrangements that have succeeded well in my own case for Tulips and Crocuses.

Each Crocus bulb, or rather corn, generally throws up several blossoms—as many as eight or nine in little groups, each of the white sprouts we see making one of the groups. These blossoms succeed each other quickly; so that if fading flowers are always cut off at once, and the plants are shaded from sunshine while they are in blossom, which is most essential, they will often continue gay during many days or weeks.

The Tulips, also, are very long-lasting flowers, closing up at night and opening again by day. I should be quite afraid to say how long the flowers of some of my own Van Thols have lasted; but their being in a plant-stand gave them very great advantages both as to growth and duration.

These very delightful little Tulips may be grown either in sand or soil. They answer admirably three-balls in a large 60-pot—that is nearly close together, though they should be as far apart as the sides of the pot will allow; the pot well drained with charcoal, placed so as to prevent the hole being filled; some soil mixed with a little sand; and then placing the Tulip on the soil put in lightly, the remaining part should be pressed firmly down on the bulb, leaving out only the point. Pressing the soil at the top down firmly has been most effectual with me in preventing all sorts of bulbs from rising out of it; the resistance, of course, being less below than above if this is well attended to. This is a great advantage in transplanting Hyacinths and anything of the kind. The roots are shaken lightly in and only covered firmly; and every one knows the very great discomfort of watering a too-tall flower-pot, as well as the ugly look which this gives the flower. The small red Van Thols are certainly most attractive, because they are so extremely sweet; and when they are planted three in a pot, or even two in a very small one, as I had some last winter, they are very useful for working up into any shape or pattern.

These Tulips answer most charmingly arranged with white Crocuses, or with the white Chinese Primrose.

A flower-stand fitted with one of the large glass Hyacinth-dishes alluded to last week could be thus made into a pretty pattern:—Three rows; the centre, for instance, a white Hyacinth or Narcissus surrounded with Scilla sibirica, or a blue Hyacinth surrounded with the large double Snowdrops (named expressly for in-door use); the small pots of red Van Thols alternating with pale blue Crocuses edged round with white, or with white Crocuses edged with blue Scilla.

These edgings may be easily managed, either by using rather larger pots (tumblers take up less room than flower-pots), and placing these round the edge; or by planting the Tulips, &c., and having all the interstices filled amongst the green moss with the pretty white or blue flowers. The *Lycopodium* itself grows in damp sand, and the Snowdrops and Scillas of course do perfectly.

If a Hyacinth-dish or milk-pan large enough were bought, a dish edged and fringed with Snowdrops would be very pretty filled entirely with the red Van Thol and a clear white *Or cas*, though I think it is prettiest with the blue Scilla added. In that case the centre would exactly have to match the Scilla or the Van Thol in colour; and the whole arrangement being in bands or alternate groups, the ground would require to be filled up with white. The colour of the common small blue *Periwinkle* would be just the right thing, or of the blue *Hyacinth*, alternating with Chinese Primroses, the Primroses require to be rather low, and their pots should stand also lower than the others.

The Tulips require never to become dry. The more light they have the better; but the great requirements of all are avoiding heat and dryness, and broken leaves, which is one of the great dangers I find in window gardening; but then, when people have birds which often are flying loose, their difficulties, of course, are a good deal increased—for birds are certainly passionately fond of Tulips.

With Crocuses the difficulty, if it is to be called one, is not to let them draw up. Kept in a window far from a fire it is not likely that this will really happen; and of all the useful plans for economising light, the best I know is a series of hanging-baskets—mere frames of strong wire in which to suspend these dishes while growing.

In planting Tulips it is dreadfully tempting to pull the red "cap" open to see the little shoot the sooner. If people do not do that it is the better for their Tulips.

The Van Thols and Scillas, if tolerably well managed, will be out in December early, and so will the Narcissi.

The other kinds of Van Thol might be so used according to their colour, only they are not so early.—E. A. M.

THE RED SPIDER.

THERE is nothing like taking up a position; and so I say in direct opposition to "E. T." page 399, that sulphur, if properly applied, is the best and most simple of all remedies against red spider.

Painting my chimney and flues did no good in my house; but a pan of water covered with a thick coat of sulphur, standing in a hot place directly under the Vines, has been for years a perfect preventive. The sulphur, floating in water, gives off its fumes gently and for a long time. Sulphur used with lime in painting flues, or the more dangerous practice of placing sulphur in pans so as to nearly melt it, is soon exhausted; it then, although its smell is perceptible, is innocuous to red spider life. If "E. T." had strewn sulphur on the surface of the soil under his Melon leaves no spider would have attacked them. Painting the frame, and placing a large pan of sulphur in it, would fill all the upper part of the frame with fumes obnoxious to the spider, while he would be living riotously on the under surface of the leaves.

I have always been accustomed to write only from my own experience, and seldom or never to theorise; and so let me tell the result of a very recent experiment on red spider.

In one of my ground vineries I have two Peach trees trained "en cordon," and pegged down to the slates. When the month of June came, in the summer just passed, I looked daily for the advent of our scarlet-coated enemy, for no plant or tree is more liable to his attacks than the Peach. About the middle of June he came, and by the end of the month so persevering was he that not a leaf was untouched. By the first week in July (for I must mention that I wished to thoroughly test the curative powers of sulphur, and so allowed him to have his way), the leaves became brown and seemed on the point of falling. Now was my time. I directed my man to take off the glass ridges, and then to lift up each tree while I strewn flowers of sulphur all over the slates on which the trees were to rest. The trees were replaced, the glass ridges placed over them, and I looked to the result of my experiment. In about a week the young leaves lost their spider-tainted appearance; and by the end of July the old leaves that I had thought dead became green and healthy, and the trees ever since have made the finest and most healthy growth possible. In the beginning of this month (September), I partially renewed the sulphur dressing as the weather was very hot and dry, but I could not see any remains of spider life. After this, "let them all say what they will," I shall believe flowers of sulphur properly applied a sure preventive and an equally sure cure for red spider. The proper mode of procedure in Melon-frames would be to place large pieces of slate on the surface of the earth, slightly sinking them so as to be level with it, cover them with a thick coat of flowers of sulphur, renewing it occasionally, and train the shoots over them. This, I have no doubt, would be as effectual with Melons as with my Peach trees.—T. R.

THIS pest is, perhaps, the most troublesome of the gardeners' enemies. The chief cause of its appearance, or prevalence, seems to me to be dryness, for it seldom attacks plants under glass where a considerable amount of moisture is present. For instance, it seldom or never fixes upon Melons while the heat from the bed is moist, and until we give a diminished supply of water or withhold it altogether, to obtain rich, well-flavoured fruit, red spider makes little progress. But so soon as the moisture becomes lessened, the spider finds a fit and proper medium for its labours, which soon (unless checked), annihilates the leaves to which it clings with remarkable tenacity, spoiling the present crop, and the future is a matter for hazardous conjecture.

The red spider cannot live in a house or frame having a greater amount of moisture than 90° (Saturation = 100), and it seldom makes its appearance where a mean humidity of 85° is kept. Neither will it thrive in a temperature (mean, below 45°), although its eggs will endure a considerable amount of frost.

We have had a severe attack this year of it on the Elm trees in this locality, which may be the chief cause of the trees being now (September 26th) almost entirely denuded of their foliage; but the drought of August, no doubt, greatly assisted. However, if the red spiders' eggs stood the last winter, which I suppose they did, it is evident their eggs will bear a very great amount of cold, no less than 35° of frost (— 3).

We may also observe that the red spider rarely infests a plant attacked by mildew. The last some writers seem to attribute more to dryness than moisture; but I never heard of it, nor have I seen mildew in a dry, well-ventilated vinery, but in such a house red spider may be seen by myriads.

The plants most liable to his attacks are those with smooth leaves, whose texture is hard to the touch and without hairs, as

Gardenias, Francisceas, Chorozemas, Clianthus, &c.; amongst fruit-bearers, Peaches, Vines, Pears, Plums, Figs, and Melons; but we seldom have any trouble with it on Geraniums, Biononias, Glorinas, or Achimenes, &c., which have hairs on the leaves; or on succulent plants either, as Cacti, &c.

In order to combat successfully against it two things are necessary—first, the operations for its destruction should be accompanied with considerable moisture; second, a healthy state of the plant should be promoted above the leaves and below the roots, which will do more than all the nostrums in the universe.

The following nostrum may be as old as the hills for anything that I know to the contrary; it is made as follows:—Take 7 lbs. sulphur vivum, 1 lump of lime unslacked, the size of both hands; boil in 3 gallons of rain water for a quarter of an hour, then add 2 lbs. of soft soap, and 1 lb. of tobacco; add 9 gallons of rain-water, and boil again for half an hour. The liquid should be gently stirred all the time. Allow the mixture to remain until cold, it may then be put into stone bottles well corked. It may be used when fresh made, or it will keep for years. After being kept three months it will be clear, having the appearance of "stout," for which it might easily be passed off so far as looks are concerned.

APPLICATION.—First, in its pure state to the wood of Vines, or the wood of any plants liable to be attacked by red spider, thrips, aphid (green, brown, and black), having previously been heated to 140°.

Second, one pint (imperial) to 3 gallons of water, which imparts to the water a white colour, or exactly like old milk: this applied to the Peach trees after the fruit is set destroys the aphides that generally infest the trees about that period. A syringe is necessary; and another point must be attended to—thoroughly wetting every shoot and every leaf on both sides. If this be repeated every fifteen days from the first syringing with it to the second week in August, or until the fruit begins to ripen, very little spider will show itself, or any insect either. It is equally efficacious when used to any plants having smooth leaves, but it destroys the leaves of plants that are woolly, downy, or hairy, and so does any composition or liquid that contains soap, unless highly diluted with water.

To clear plants in pots of red spider, take 2 lbs. of soft soap, place it in 8 gallons of water (mix, of course), heated to 140°, dip the plants infested into it for half a minute, let them stand until dry, then dip again in the water at a temperature of 120° for one minute, and the spiders' days are numbered. If the plants are infested with brown scale, rub the infested parts with the hand, dipping a time or two more than for red spider. By these means we get rid of the brown scale and mealy bug also. The further this solution is from Geraniums and plants having similar foliage the better.

Both these above mentioned are difficult to apply to some plants, as Melons, &c. With Melons that are pestered with red spider, I treat as hereafter—1 lb. of flowers of sulphur mixed (by hand) with 3 gallons of lukewarm water (110°). On a fine day having a cloudless sky, at 2 o'clock in the afternoon precisely, I take a wide-rosetted syringe and fill it with water (for if the sulphur is properly mixed it sinks to the bottom) from the bucket containing the liquid, forcing it out into the same (this makes it all alike), the next two syringefuls are sprinkled on the plants. The next one returns to the bucket as before, and so on until the plants are thoroughly wetted. Then shut up close, shading with a single thickness of tiffany, and treat them the next day in the usual way. The day after that let the plants be lightly syringed overhead (omitting the necks of the plants), afterwards shutting up close at 2 P.M., &c., as before; following this course for a week, and we shall find our fruit well ripen, and if not too late a second crop will follow.

However, if the spider has made such havoc that the leaves are half a yellow or greenish-white colour, we can then destroy the spider; but to cause these leaves to become healthy and green, so necessary to ripen the crop properly, this remedy will not do that, neither am I able to point out any nostrum that will. The above is equally efficacious for mildew on any plants whatever; and, used for that purpose, there is no need of shutting up the house, but only syringe it on (which is done in half the time as dusting with sulphur is), giving more heat and ventilation, but less moisture.

This year we have had more red spider than ever I remember; but having sulphured the flues and pipes it has been kept within reasonable bounds, except in the orchard-house, where, owing to

water being scarce, the trees were seldom syringed—in fact, they had not plenty at the roots, so the spider held absolute sway all August and into September against sulphur-basins or evaporating-troughs; when water being plentiful the spider at last yielded. I used water freely by syringing, for there was no fruit to spoil, owing to the wood never ripening last season, the frost killed greater part of the wood, no bloom at all showing the trees were cut in; but there is every prospect of a fine bloom next season, notwithstanding what red spider has done for us.

With your correspondent "E. T.," I believe moisture combined with a healthy growth will greatly assist any remedy for destroying red spider, or any other disease, be it insect or virus.—GEORGE ABBEY, *Gardener, Horton Hall, Bradford, Yorkshire.*

POTATOES WHICH HAVE NEVER BEEN DISEASED.

AFTER the notice you were pleased to take of my communication, and inserting it on March the 5th, No. 649, page 333, of THE COTTAGE GARDENER, respecting the Potato disease, I was fully determined to forward to you for your notice and inspection this autumn a sample of a variety of Potatoes out of many I have unremittently and carefully cultivated, and tried various experiments with, to find, if not a preventive, a check to the disease; and if you will be pleased to describe the Potato I forward in THE JOURNAL OF HORTICULTURE, at your convenience, some of the numerous readers and subscribers, I have no doubt, will recognise it. The same variety has been grown in the west of England for many years, and in different counties it goes by different names, as the Rough Red Kidney, the White-eye Kidney, the White Red Kidney, &c. It is not the name alone, colour, or shape, I wish to call to your notice; it is the only variety I have found to be free from the disease, when all others are more or less affected. This and last year with me it was entirely free. The sample I forward is a true sample taken out of the bulk after being lifted, and grown amongst several other sorts in the same garden, and very often I plant two varieties in the same row, to test the effect of the disease upon different varieties; and I do without hesitation avouch, that if the variety was carefully selected and cultivated in the way I described in THE COTTAGE GARDENER in March last, the disease would be less heard of. I shall be most happy to send two or three pecks to you, so that you can place them in different individuals' hands to try them next year. The impression upon my mind ten years ago, when I first commenced a series of experiments in cultivating the Potato, was that not all and every individual variety of that valuable root was equally liable to a disease that has baffled science to find a cause or a cure. Surely there are, with judicious care in selection and cultivation, some that can be saved and be proof against the disease.—J. DOWN, *Gardener, Woolston, near Wincanton, Somerset.*

[The variety nearly resembling the sample you have sent is one we have not seen for some years. It was known to us as the large-eyed variety of the Perthshire Red, and like yours was kidney-shaped, medium size, dull red, rather deeper coloured round the eyes, which were deeply sunk, and stalk end deeply basined. If any of our readers wish to try this undiseased variety, they must apply to Mr. Down, taking care that he is not subjected to any loss. The Apple enclosed with the Potatoes is the Downton Pippin, and the Pear the Chaumontel grown on a standard tree.—EDS. J. OF H.]

PERMANENT GREEN GARDEN-EDGING.

I WILL premise by saying few persons are more attached to their flower garden than your present correspondent, or expend, so far as a quarter of an acre will allow, a greater amount of time, expense, or trouble in its adornment. I unfortunately lie at the foot of a hill, and from this cause the severity of winters affects my neighbours and self somewhat heavily. Although not disposed to give way to trifles, there is one mishap, that by almost invariable annual repetition quite upsets further persistency.

The Box edgings die quite away nearly every year, and for many years past I have annually been compelled to incur several pounds expense in replacing it at spring-time, simply with the certain result of seeing it as bad as before, in less than the same time next season.

I confess I like Box far better than anything else I have yet seen as edging, although I have visited the gardens of many of our aristocracy. It looks more like the country, the usual grey-coloured garden edge-tiles appearing to my mind very town-like—in fact, too much of the city character to suit my fancy. Several of my close neighbours have replaced the Box to their flower-borders with iron edgings, grey stone ones, and even boarded ones. The latter party by painting has certainly produced the best effect of any, but the paint, naturally, is gone almost as soon as finished, and the dampness of the material, now it is fixed, prevents its successful repetition. As I shall want some hundreds of yards to refit my own little place, I am anxious to do so in the most effective and permanent way possible, and should feel greatly obliged if you could advise me how I could get a plain, neat-looking border-edging made at the outset of a nice clear green colour, without painting, as I fancy that colour to be most suitable as a relief to flower-borders, and wish to get it so indestructible as to require no further attention after once laying down. Again, if you can devise anything preferable for the purpose of flower-borders exclusively, I shall, as will many others in my locality, esteem the information as a peculiar obligation.—EDWD. HEWITT, *Sparkbrook.*

[It so happened the very day this note arrived, that we had submitted to us for our opinion an edging made of green glass. It is very stout, is pleasing to the eye, and very durable. Moreover, it is cheap, for the manufacturer says that it can be made for 1s. 6d. per yard. We shall say more upon the subject so soon as we see the manufacturer again, and find that he is ready to execute orders.—EDS. J. OF H.]

TROPEOLUM FOR A WIRE FENCE—FLOWERS FOR EDGINGS AND BEDS.

WHICH would be the best species of Indian Cress to cover a low wire fence 20 inches high? Would Cattell's Dwarf sorts answer?

Would a bed of yellow Calceolarias look well if edged with *Perilla nankiensis* pegged down? Or how would *Cineraria maritima* look also pegged down, or *Saponaria calabrica*, or *Cerastium tomentosum*?

Can *Gnetha macrocarpa* be depended upon for making a good flowering bed?—SENATEUR VAISSE.

[Elegans would be the best of all the Indian Cresses to cover a wire fence 20 inches high and up to the height of 4 feet. Cattell's new seedlings are of the Tom Thumb tribe and would not do, but they are good bedders.

Perilla would make a good edging to a bed of yellow Calceolarias. *Cineraria maritima* would also make a good edging, and so would *Cerastium tomentosum*; but *Saponaria calabrica* would not make a good edging to any flower-bed that we can think of.

Gnetha macrocarpa may be depended on for constant flowering after the first season of planting the bed, but not for the first season, unless the plants were very good and out of pots.]

CULTIVATION OF PLUMS ON THEIR OWN ROOTS.

As the season is approaching for putting in Plum cuttings, I now remind the readers of THE JOURNAL OF HORTICULTURE, by giving a few more details than were written by Mr. Beaton last year. When corresponding with him on the subject, I told him it was the best way, and will now give my reasons for having come to that conclusion.

Among the first ideas that young gardeners imbibe is that certain sorts of fruit-bearing trees must be grafted upon some particular stock, and for the Plum there are several usually employed. These which I am acquainted with and have used are six, not including seedlings. These six I have grown and fruited for observation, such as their hardness, durability, fruitfulness, and propensity to throw up broods of suckers.

It is evident that the Plum has a natural tendency to send up suckers, and this peculiarity may be strengthened—first, by propagating in a way favourable to that tendency; and secondly, by grafting on them a variety with a different constitution, for however free the Morocco may receive the crude ascending sap from a stock of the White Pear Plum, it does not thrive with the elaborated descending sap of the Morocco: hence the stock resorts to its natural resources in throwing up suckers. Some of

these stocks are considered to bring the choice sorts into an early bearing state. This can only be the case where the stock cramps the natural energies of the graft, and it is seldom that the stock and graft swell of an equal size, and although not always the case, it is generally so that the stock is the smallest. There is only one variety of Plum-stock that I have practised with that invariably swells larger than the graft; but even this stock that receives freely the descending sap of others, gives no advantage over those trees on their own roots, for with such the cultivator has a whole tree, root, and top, with one constitution. Budding and grafting I look upon as a necessity, from the facility they offer in propagating on an extensive scale; but only as such, for when judiciously applied they cause the greatest blight that befalls the fruit.

The advantages of a Plum tree on its roots are a sound healthy tree, with every appearance of being long-lived, coming naturally early into bearing, surpassed by none for productiveness, with no rubbish of suckers to pester the cultivator, and the easiest way to propagate it. And this last I look upon as a boon to the amateur and cottager who have a favourite Plum they wish to increase, but for want of a stock, or, more probably, their ignorance of grafting, they are deprived of the pleasure and economy of raising their own tree; and the chances of success that a novice would have with a Plum-graft and a good cutting are too far apart for comparison.

For preparing and planting the cutting, take a two-year-old shoot, the stronger it is the surer of growing, and the sooner a fruiting tree. A mere strawmat of a twig will not do; it must be of a certain substance, containing a store of the material to send down to make roots before the leaf calls for supplies. As a guidance, no shoot ought to be used less than half an inch in diameter at the base. Shorten all the side shoots or fruit-spurs to half an inch or an inch, take a small slice of bark off at opposite sides at the bottom 3 inches long, or more.

The first object the cutting makes to root is to callus round the edges where the bark is taken off, and from this callus spring tufts of roots. However, they will root without this preparation; but it has an advantage. Prepare a piece of ground by digging and breaking it fine, then firm it down by trampling; into this force the cutting 8 inches, observing that it is perfectly firm. If the ground is light a good mulching will be a benefit.

The season for putting in cuttings is an important point, although, like many other gardening operations, it does not require to be done on a certain day or week to insure success. To be early is to err on the safe side, and it is better to put in the cutting by the middle of September than leave it to the latter end of December, or later. I have generally confined myself to the fall of the leaf—about the second week in November, with success. If they were put in where they are not intended to remain permanently, they gain strength faster by remaining two seasons in the same place before transplanting. The first season they are weak, much resembling a tree that has suffered from transplanting, after this they rapidly gain strength from year to year.

What wood they make the first year should be cut back as when the cutting was prepared. After this pruning, if an object is to get them into an early bearing state, use the knife as much as possible in the growing season. All that is required is to form the tree, whether for the wall, dwarf, or full-grown standard. The latter when full grown require but little pruning, keeping them thin of wood is, however, necessary. For the full-bearing wall tree the knife must be freely used, by cutting out old and exhausted wood, and laying in a yearly supply of young shoots. This is the sound principle of Plum training, for it insures a crop, and that of the finest quality. The shoots must be laid in their whole length, for if shortened the chances are a crop of wood instead of fruit would be the result. It is the spurs that the young wood makes the second season that can be depended upon. These fruitful spurs are those directed to be cut back when the cutting is prepared, and it is probable this fruitfulness and the rooting of the cutting may be traced to the same source—viz., from the two-year-old wood being abundantly stored with organizable matter, for I have observed that the blossom-buds left on the cutting expand with the appearance of strength as if they had never been removed from the parent tree, but it is seldom the fruit sets, and only on two occasions have I seen it come to perfection. To return to the pruning. Avoid shortening the fruit-spurs, for it often happens that all the buds except the one at the point are flower-buds, and if

shortened there is no leaf left beyond the fruit, which is essential for having high-flavoured fruit. All that are longer than 3 inches or 4 inches, if forlorn, to be cut clean off, the others thinned out and fastened to the wall, and at the next winter pruning what is not wanted to replenish the tree with wood cut them clean off. By this, old spurring is avoided, and by using the knife freely the tree is kept in a vigorous, healthy state.

If a Plum tree does not make young wood the fruit will not be of the first quality, and such a tree is liable to become the prey of insects, from being in a stunted, unhealthy state, arising from some cause or other, and too often from being worked on a stock which has become paralysed from the position it is placed in: hence an advantage of Plums on their own roots.—A. M'KELVIE, *Steeventone, near Torrington.*

LONDON AND ITS NEIGHBOURHOOD ONE HUNDRED YEARS AGO.

If a graphic and minutely particular account of any country, its inhabitants, and their manners and habits is required, employ for its preparation an intelligent foreigner about to visit it for the first time. To him everything will be novel and be noted; whereas if you employ as your reporter an old inhabitant of the country, he will leave uncriticised the greater part of subjects of especial interest, for no more valid reason than that he thinks every one else must be as well acquainted with them as himself.

No better illustrations of this truth can be obtained than from two volumes now before us, published in the year 1772, entitled, "A Tour to London, or New Observations on England and its Inhabitants. By M. Grosley, F.R.S., Member of the Royal Academies of Inscriptions and Belles Lettres." His descriptions are so unimpeachable, and afford such ample materials for contrasting what we were then with what we are now, that we feel assured that our readers will be as much amused as we have been by the extracts we shall place before them. Before doing so we will briefly relate who was their author.

PIERRE JEAN GROSLEY was born at Troyes, Nov. 18th, 1718. He lost his father, a celebrated lawyer of the district, when he was fourteen years old, and like many other youths of ardent temperament, he seemed to fear himself, and wished to enter the Oratoire. From this he was dissuaded, and he went to Paris and fell in with men very different from ecclesiastics—Voltaire, Piron, and Le Franc. Returning to Troyes he succeeded to his father's practice, yet found time for his favourite pursuits—*belles lettres*, the arts, and travelling. In 1745 he went to Italy, and being employed in the administration of the army, was in the campaign of 1746. Again returning to Troyes, he was made syndic in 1751. He afterwards accepted the grand mayoralty of St. Loup, and was also bailiff of Chasses and Vancharis. On his uncle's death, by which he inherited 21,000,000 francs, though not rich, he gave a portion to his sister, and devoted a large portion of his income to the erection of busts to the memory of his illustrious countrymen. Adverse fortune compelled him to abandon this expense, but he never gave up his fondness for literary pursuits. *Pais et pen* (quiet and little) was his maxim. In 1758, he the second time visited Italy, in 1765 England, and in 1772 Holland. He died Nov. 4th, 1785.

"EMBANKING THE THAMES.—They will proceed by degrees to clear the river, to open communications with it, and, in fine, to border it with quays, in the very body of which it will be an easy matter to contrive proper places for loading and unloading. These quays being once opened, the first noblemen, the wealthiest merchants, the richest of those who undertake to fit out privateers, allured, some of them by the grand and noble prospect, others by the convenience of commerce, will come to build upon the banks of the Thames in emulation of each other; and that river will at last be as much frequented as it deserves. Then the improvement of London will resemble that of Lyons. So long as Lyons was confined to the quarter of Fourviere, its construction prevented it from having a view of either the Saone or the Rhone, which its first founders endeavoured to procure. Since it descended to the confluence, the quays, which it has opened itself upon both rivers, have given it all the advantages that might result from its situation, the principal of which is, being out of danger of the contagion of the plague and other epidemical disorders by a free circulation of air.

"Such are, with regard to the city of London, the views and hopes of the architect of the new bridge, as he explained them to me himself. 'I will even leave them,' added he, 'a model of

what they are capable of doing in this way, by joining my bridge to the old one by a quay, so that there will be nothing more to do but to continue it, when reason has at last overcome old prejudices."

"The bridge which this architect is building has not yet received a name. Some are for calling it Pitt's bridge, from the present English Demosthenes; those in the party opposite to Mr. Pitt are for calling it Blackfriars Bridge, from a monastery that had been demolished in the place which it occupies. Whatever may be its name, it will surpass even Westminster Bridge in boldness and in the magnificence of its decorations. It was to have been built in five years, during each of which the parliament assigned the architect 300 guineas. Various accidents and obstructions have protracted the building of it, which in 1765 was in its fifth year."

"DIRT OF LONDON—ENGLISH GRAVEL.—In the most beautiful part of the Strand, and near St. Clement's Church, I have, during my whole stay in London, seen the middle of the street constantly foul with a dirty puddle to the height of 3 or 4 inches; a puddle where splashing cover those who walk on foot, fill coaches when their windows happen not to be up, and bedaub all the lower parts of such houses as are exposed to it. In consequence of this, the promities are frequently employed in washing the fronts of their houses, in order to take off the daubings of dirt which they had contracted overnight.

"The English are not afraid of this dirt, being defended from it by their wigs of a brownish curling hair, their black stockings, and their blue surtouts which are made in the form of a night-gown."

"To enable the reader to judge how frequently this daubing must happen, it will be sufficient to inform him that the pavement of London is formed of stones just as when taken out of the quarry. These stones, which are almost entirely round, have neither tail, foot, nor any part so formed as to stand upon; they roll about and hit one another incessantly upon a bottom, which is nothing else but a heap of old dirt. The whole art of the pavior consists in placing these stones as near each other as possible; yet, bad as it is, this pavement is exceeding dear, there being no materials for it in the neighbourhood of London, but sand, gravel, and chalk. With regard to the freestone pavement, the materials of it are brought at a great expense from the extremities of the kingdom, and it is one of the dearest commodities in London. If we may believe a story told by the people of London, Louis XIV. offered to supply Charles II. with freestone to pave his capital, upon condition that the English monarch should furnish him with that fine gravel with which the English strew the walks in their gardens, and which when well rolled assumes the smoothness of a bowling-green.

"Means, however, have been found to pave with freestone the great street called Parliament Street, which reaches from Westminster Abbey to Charing Cross. The fine street called Pall Mall is already paved in part with this stone; and they have also begun to new pave the Strand. The two first of these streets were dry in May, all the rest of the town being still covered with heaps of dirt. It was even customary to water them as well as the bridges and the high roads in the neighbourhood of London. This has been a practice in England time out of mind, and was some years ago introduced at Paris by Joseph Outrequin."

WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from page 502.)

CRUSTACEA—(continued).

THE BANDED SHRIMP (*Crangon fasciatus*).—Our knowledge of this pretty little specimen, which is indigenous to our coasts, is due to Professor Bell, who found three of them amongst some small Crustacea taken in Salecombe Bay, Devonshire. The Banded Shrimp very much resembles the common Shrimp, although it is smaller, and distinct in other particulars. Its chief peculiarities, however, are "a remarkable brown band across the fourth segment of the abdomen, and a spot or two of the same colour on the sides." It measures in length about six-tenths of an inch.

THE SCULPTURED SHRIMP (*Crangon sculptus*).—The shell of this strange creature is rough, having five or more raised lines, each armed with two or three small teeth. It derives its name from the distinct sculpture seen on the abdomen. Its length is about seven-tenths of an inch, and has been dredged off Wey-

mouth. There are several other species of Shrimp—for instance, the SPINOUS SHRIMP (*Crangon spinosus*), the THREE-SPIRED SHRIMP (*Crangon tri-spinosus*), and the TWO-SPIRED SHRIMP (*Crangon bi-spinosus*); but they are very rare on our coasts—so rare, indeed, that of the last two kinds Professor Bell had not seen a single specimen; the mere mention of them will, therefore, be sufficient.

We now proceed to the

PRAWNS (Genus *Palaemon*).

The greater number of species of this genus are of small size, although in the tropical seas some have been known to reach a foot in length. Professor Bell gives an account of four British species, each distinct from the other; we will, therefore, proceed to examine the four enumerated by him.

THE COMMON PRAWN (*Palaemon serratus*).—Although a description of these very familiar creatures would seem almost superfluous, still a few of their points must be mentioned for the satisfaction of such as may meet with them in their wanderings; as it is hardly necessary to remark, an animal of this description, in the fulness of life and activity, presents a somewhat different appearance to that which it assumes when cooked and stretched out upon the breakfast table.

The shell of the common Prawn is even and rounded. It has a long beak armed with seven or eight teeth; the eyes are round and large; antennae very long, about half as long again as the creature itself. It has, as usual, five pairs of legs, the first, or anterior pair, very slender, the second extending nearly to the extremity of the beak, the remaining pairs simple and slender; the false feet of the abdomen extremely long; the last joint of the abdomen narrowing to a point and armed with teeth, the tail-plates provided with long hairs. Its length is ordinarily about four inches or upwards. In colour it is of a bright semi-transparent grey, lined and spotted with grey of a much darker hue.

The common Prawn is found in considerable numbers on all our coasts. As before mentioned, loads of them are taken in shrimp-nets, and sold as Shrimps in several places. These are the young of the Prawns, which retain the name of Shrimps even on reaching a middle size, only acquiring their proper nomenclature when they attain the largest dimensions. Their favourite haunt is the clear bright water in the rocky parts of the shores. The ordinary mode of taking them is by means of pots resembling the lobster-pots, but made of more delicate material. The chief supply for London is furnished from the Isle of Wight and Hampshire coasts; but as they deteriorate in the interval between the time of their capture and that of reaching their destination, a real treat of Prawns must be enjoyed in the fresh bright precincts of Shanklin and the Undercliff.

SMALL PRAWN (*Palaemon squilla*).—This specimen chiefly differs from the former in its size, not being above half the length; the other distinctions between the *Palaemon squilla* and the common Prawn being so slight as scarcely to warrant notice, save for the purposes of scientific examination. They chiefly consist in the beak, which is almost straight, having but a very slight curve towards the end; whereas that of the common Prawn is very long, and ascends after a progress of about half way. The length of this creature is about two inches, and is to be found on most, if not all of our coasts, particularly on that of Devonshire, where, indeed, it forms the chief part of the Shrimps sold there.

LEACH'S PRAWN (*Palaemon Leachi*), is another of the creatures sold at Poole as a Shrimp. Its general appearance to a casual observer is similar to that of both the preceding specimens; but on a closer examination a difference will be found to exist in the formation of the beak again; but unless carefully examined the distinction of formation is not perceptible. A more marked variation, however, is found in the beak of this specimen being covered with reddish spots, which are entirely wanting in the *Palaemon squilla*.

VARIABLE PRAWN (*Palaemon varians*).—This is a small specimen by no means so common on our coasts as those previously mentioned. It has fewer teeth on the beak, which is perfectly straight and sharply pointed. The antennae are also shorter than in the other specimens, not exceeding the length of the creature's body.

We will now take a view of the Lobsters and Crayfish, which also belong to the class Decapoda (ten-footed), and *Merus*, (or long-tailed).

THE COMMON LOBSTER (*Homarus vulgaris*).—The body of the common Lobster is round and thick; the cephalothorax long and compressed at the sides; the beak is short, and armed with four teeth on either side; the eyes are round and comparatively small; the abdomen is semi-cylindrical, the sections smooth, and terminating on each side in a flat triangular plate; the tail is broad; the anterior legs very large and powerful; they are unequal, however—one being larger than the other, the larger one having strong tubercles on the inner edge of the fingers, the smaller one being furnished with small sharp teeth instead. The other legs are thin and weak, the second and third pairs having two fingers, the fourth and fifth only one.

In colour the common Lobster is usually of a dull, pale, reddish-yellow, spotted with bluish black. It is taken on many parts of the coast, more particularly in rocky localities. Southampton, Bristol, Jersey, and Guernsey supply a vast number to the London markets. Scotland, the Orkneys, also, furnish a large quota; but by far the most considerable number is sent from Norway, whence it is said we receive 600,000 during the season, which extends from March to August. Lobsters are by no means migratory in their habits, never straying far from their birthplace; the discovery, therefore, of a new settlement is a lucky thing for the fisherman. With regard to the casting of the shell, we shall not have any necessity to add anything to what was said in a previous chapter.

Lobsters are incredibly prolific; but the great extent to which the young ones fall a prey to fish of various descriptions serves to keep the race a little within bounds.—W.

(To be continued.)

GROUND VINERIES.

I HAVE the great pleasure of sending you some ripe Grapes from my "Ground" *ci devant* "Curate's Vinery." From the first I felt a strong impression that these useful, cheap structures would be a great boon to us small gardeners. It is, therefore, with great glee that I send you some berries of Black Frontignan and ditto of Chasselas Noir Grapes. Neither of these are early sorts, yet I think you will find them ripe and of good flavour. They would lie on their floor of slate for another month and become dead ripe; but I have thought it better to send them now (Sept. 25), so that you might judge of the ripening power of these glass ridges. As I am a fortnight later than the western and southern suburbs of London—say Fulham and Chiswick, I feel tolerably certain that Black Hamburg Grapes would be fully ripe now in those neighbourhoods; for in my ground vinery adjoining that from which I have gathered the fruit of Chasselas Noir are some Hamburgs fully coloured, which will be ripe in a week. The Hamburg Grape ripens in the open air in the south of France about the second week in September; so that with our glass and skill we are not much behind a climate so favoured. But how gratifying is the thought that good Grapes may be grown in all our London suburban gardens with a sunny aspect in the highest perfection, with the aid of a few bricks and a ridge of glass. May I, therefore, hope that you will repeat the figure and description you gave in your Journal? You have many new readers, and every one ought to see the method and as soon as possible practise it. There is now no doubt, no fear.

To Dr. Samuel Newington, of Ticehurst, the horticultural world is indebted for this most simple yet efficient method of growing Grapes. His method was, however, different to that which I practise, and from a vinery under which system I send the Grapes for you to taste. "SIGMA'S" invention, which Mr. Rivers named "the curate's vinery," was a ridge of glass placed over a trench or furrow lined with slates; over this trench the stem of the Vine was suspended by cross-pieces of wood or iron, and the bunches of Grapes were to hang in the trench, so as to be a little below the surface of the adjoining soil. My vineries have no trench, but are merely ridges of glass placed on bricks, the soil under the ridge being paved with slates. On these the Vine rests, and the bunches of Grapes lie; and, owing to the excessive heat of the surface on which they rest, they ripen early and thoroughly. Let me earnestly advise all those who love ripe Grapes (and who does not?) and who have no vineries, no garden large enough for them, and, above all, no money to spare to build them, to buy some of these glass ridges or make them. They are easily made if they cannot be bought. Any amateur carpenter could make them; and what

a comfort they are capable of being made to the proprietor of a small garden, who could have two or three fine Black Hamburg Vines, each 14 feet long, and each capable of bearing twenty bunches.—MUSCAT.

[These Grapes were of a jet black colour, perfectly ripe, and the muscat flavour of the Black Frontignan was quite full. This is an admirably simple way of growing Grapes. Below are the figure and description our correspondent refers to.—EDS. J. OF H.]

"Place two rows of bricks endwise (leaving 4 inches between each brick for ventilation) on a nice level piece of sandy ground, and then paved between them with large slates ('duchesses') placed crosswise. On the bricks place two of the ridges of glass, as given in the foregoing figure, each 7½ feet long, and thus form the vinery 15 feet in length. One Vine will in the course of two years fill a vinery of this length; but to reap the fruits of the project quickly, plant two Vines, one in the centre, the other at the north-east end: for these structures should stand north-east and south-west."]

SUCCESSFUL STRAWBERRY CULTURE.

In fulfilment of my promise, I now communicate to your Journal a method of growing Strawberries, the most successful I have hitherto adopted, and which, I consider, insures a crop of extraordinary productiveness at the least possible expense and trouble.

In the preparation of the ground previously to planting, the usual course of double trenching and well mixing good rotted manure is to be decidedly recommended, and the plants to be set in rows 30 inches apart in the spring, having been first planted in a nursery-bed in the previous autumn. I consider this advisable, because in the spring any weak plants may be repotted, and a regularity of plant secured. Nothing more that season is necessary beyond occasional watering after planting, and care taken to clear away the runners, and avoiding fruiting as much as possible. The second spring after planting I recommend, just before the flowers open, a thorough watering with liquid manure, say two good-sized watering-pots, to be given to the square yard. Let it be poured over the whole surface of the soil, and as the watering is proceeded with, let a quantity of bean chaff be ready, with as much dust in it as comes from the dressing-machine where the Beans are winnowed, mixed with it. The dust having been separated from the chaff in the operation of dressing the Beans, let the whole surface of the ground have of this mixture at least 3 inches in depth applied, and close up to the crown of the plants. After this let some wheat straw, bean straw, or clover seed straw (the latter I prefer, as it is the more slightly), be cut into one-inch lengths with a chaff-cutter, and let this be sprinkled on the top of the bean chaff to keep the fruit clean; and now no more watering will be necessary for this season, for no storm will penetrate the covering, and no sun will evaporate the moisture. A tremendous thunderstorm passed over my bed of Strawberries last year, but it did not percolate through the covering beyond half an inch, though, of course, it proved beneficial to the foliage.

The chaff I laid on this spring is now decaying into a fine black leaf mould, exciting the Strawberry-roots to increased action, and laying the foundation of increased productiveness for next year. Although my fruit this year was extraordinarily large, I anticipate increased size next, in consequence of the benefit to be derived from this leaf mould. I by no means recommend its application before the winter sets in, as it might encourage wireworms and other insects, but just as the Strawberries are getting into bloom.

Probably by some of your readers it may be difficult to procure

the bean chaff; but any one residing in a neighbourhood where Beans are grown, could easily procure it of the grower at about 2*l.* per bushel, and who would probably supply him with the cut chaff at the same price. This application may be thought rather expensive, but it must be remembered it is answering two purposes—doing away with the trouble and cost of repeated waterings, at the same time giving a coat of manure highly conducive to increased production of fruit. My attention was first drawn to the stimulating power of the bean chaff by having seen the effect of some I had directed to be thrown on a pasture, which was surprising, and which led me to direct its application to my Strawberry-beds.

I have now given you as concisely as in my power a method which I can practically recommend to your readers, and trust that many who, with myself, have received the most courteous and practical replies to their inquiries through your Journal, may in return give any information in their power which would assist the conductors, and at the same time afford acceptable information to the subscribers to THE JOURNAL OF HORTICULTURE.—A. GORDON, *Crystal Palace*.

GERANIUM CUTTINGS—VERBENA LAYERS.

Do Mr. Beaton's remarks on striking Geranium cuttings in September and October apply to striking under a hand-light in the open borders, or in a cold frame, or, at all events, without heat? I presume it can only be meant where heat can be given, and the late-rooted cuttings kept in a warm greenhouse through the winter, and not where they could only be kept just free from frost.

Will cuttings taken up from the borders now (just rooted) keep as well through the winter by putting eight or ten together in a large pot or deep pan, as separately in small pots—no warmth in either case?

And can well-rooted Verbena layers be kept through the winter in a cold frame or cold conservatory?—A LADY.

[After the middle of September, Geranium cuttings are not made by gardeners under hand-glasses in the open borders, because the frost would be upon them ere they rooted. Late autumn cuttings of Geraniums are always set in pots, middle-sized pots, or 4*s*'s and 3*2*'s; they are planted round the sides of the pots as thick as they will stand, and none in the middle of the pot. The pots are then put in a cold frame, or in a pit or house, as the case may be, but they never want bottom heat nor much watering. October cuttings should hardly make a new leaf till the new year, and that saves room wonderfully. But a warm greenhouse is a luxury, and the best of all places for Geranium cuttings to winter.

Rooted cuttings taken up now would do better in single pots; but for want of room we are compelled to cram ever so many of them into pots, and those not very large ones.

Well-rooted layers of Verbenas will keep far better in a cold pit than in the best conservatory. The fly takes to them so ravenously in houses that there is no keeping them alive; besides, they seem to like a cool, moist atmosphere.]

WATERING POTTED BULBS—CUTTINGS OF VARIEGATED ARABIS.

Will you be good enough to inform me, if bulbs (Hyacinths, Crocuses, Tulips, &c.), when potted in soil neither wet nor dry, and to be put in a dark, damp cellar where the mould will keep quite as moist as when potted, should be watered in before put away? or will they be sufficiently moist in the cellar without watering until rooted and brought out? If to be watered, should they stay in the air until a good deal of the moisture has evaporated, before being put in the cellar? and is plain garden mould better for Crocuses than a compost with leaf mould and sand added? Will cuttings of Variegated Arabis struck in September and October live out of doors and unprotected through the winter?—G. L.

[Hyacinths, Tulips, Crocuses, and all other bulbs without roots at the time of potting should be put in soil between wet and dry, and if the soil could be kept in that state as your damp cellar will do, the pots ought not to be watered till the leaves are seen; but you must take care that the dampness of the cellar does not cause the top part of the Hyacinths to mould.

Crocuses will do in any good garden soil just as well as in the best prepared compost. We believe cuttings of the Variegated Alyssum will root out of doors, if they are put in from the middle of September to the end of November. We have put some in last week, and we have many more to put in yet. The cuttings ought not to be put in close together, as the soil between them must be gently pressed down after frost. Put them in single rows 3 inches apart, and 1 inch clear from leaf to leaf in the row, and you will be on a footing with your instructors.]

CHOICE WILD FLOWERS.

We here and there meet with one who grows a few of our rare wild flowers, yet it is only in some secluded out-of-the-way spot where such a rarity can be found. Many of us tread under foot, without the least notice, plants which, if they were more rare, would be highly prized, and cultivated with care and delight.

Our beautiful winter greens, *Pyrola media* and *rotundifolia*, would be grown in our gardens if they were natives of some foreign clime, but being British wild flowers they are neglected, except by a very few who know and value them.

The blood-coloured Cranesbill (*Geranium sanguineum*) is a lovely plant for the cottage garden. Its purplish-red coloured flowers are very pretty; they are about the size of a shilling, and somewhat shaped like a Petunia, and I have known them called by that name. They may be found on the plants from May to the end of September, and in favourable seasons far into October. In a suitable situation the plants will grow a foot high, yet in many are trailing plants; but always form a pleasing object either in front of the mixed border or rockery. It is a plant which will grow in the same situation without any care or attention for a lifetime. I have a plant in my mind's eye which has experienced some rough treatment, yet is still healthy and growing in the same spot where it has grown for more than half a century. I have grown it in pots with protection from cold, but with me it always grows and flowers best in the open ground. It is easily increased by root division or by seed, of which there is abundance this season—my plants are loaded. We number *G. sanguineum* in our Yorkshire flora. Plants may be found sparingly in many places; but so far as I am aware it is never found growing truly wild, except on the limestone, and in our gardens seems to grow and flower best where there is a mixture of old lime in the soil.

Geranium lancastriense (Lancashire Cranesbill) is rather smaller in the foliage than the preceding; the flowers with me are about the same size, colour white, veined with red. It will grow and flower well in any good garden soil, and is easily increased by dividing the roots in the early part of the growing season. This Cranesbill is not often found in gardens, nurserymen too often sending out *G. sanguineum* in lieu of it. I have had it sent so from nurserymen. Not having it, and wishing to have it in my garden, a friend who got it in Lancashire kindly gave me a small plant. Those who do not grow these wild flowers in their gardens ought to try them, and I feel assured they will not be disappointed.—RUSTIC ROBIN.

THE VINES IN POTS AT WORKSOP.

It has been a question from the first whether, according to the wording of the schedule, I was not entitled to the prize. You have, I believe, now opened their eyes to the fact that the schedule was not worded in the proper sense—the thing, you are quite aware, that I always disputed, and which I fully consider entitles me to the prize. It is much to be regretted that the Judges did not turn the Vines out of the pots; they would have seen one Vine (only), had any roots more than 6 inches in length. One Vine only had got away; but not as your correspondents insinuate, from the bottom, for not one root came through the hole; but one pot having a hole in the side, the roots got through against the wall of the pit where the Vine was standing, and ran along by it some length. That is the dispute, and in order that I would not act dishonourably, I had every piece of root taken to the Show, well knowing it mattered but little according to the schedule whether it had roots outside the pot or not. As regards the second pot, it would not have been used at all, but it was feared the weight of the Grapes and the iron fork would burst the pot; so the roots of the Vine were brought to the top of the pot in some moss, and

the cavity was filled as I before stated with moss and water. The moss did not hide the second pot as stated, for one pot was 2 inches above the outside one. The Vines have been in perfect health, and have only been cut down the day before I got your paper—in fact, I have not quite finished one yet.

It is stated I was present last spring when the schedule was made. I well remember objecting to a prize being given at all for pot Vines in the month of September. I said such should be given in June, as any old woman could grow a Vine in September when Grapes were ripe against the open wall. I did not refuse, as stated, to have a fair statement placed before a competent authority; but as they proposed Dr. Lindley, I said, then I shall also refer to the Editors of THE JOURNAL OF HORTICULTURE, and after being nearly swallowed up by a whole host collected together for the purpose, without asking me to get a friend, although one or two were found amongst the number at last, and one the best plant grower in the county. The Meeting thus broke up.

Another correspondent states the Vines had other support than the soil contained in the pots: of course they had. Could a Vine grower be such a simpleton as to think such Vines, with thirteen bunches each, some weighing $1\frac{1}{2}$ lb., could be grown without artificial aid? No, they had soil, water, gas water, and manure water; but not one spoonful of soil beside what was in the pot: they stood only on an old spent tan-bed, containing about 8 inches of tan, and the moss was not put into the pot until the morning of the Exhibition, so that there could not be any benefit derived from that further than keeping them cool.—EDWARD BENNETT.

[Having now given Mr. Bennett space for his reply, this controversy must cease; for it can be carried no further, except to give vent to private feelings, and for such purpose our columns are not intended. Two things by the controversy have been brought to public notice, and, we hope, "settled"—1st, That however the words of a prize list may be worded, the roots of a Vine in a pot must be confined within the pot. Roots in 8 inches of spent tan outside the pot, and watered with liquid manures, would give more nourishment to a Vine than the roots inside the pot. 2nd, That the words of a schedule of prizes should be precise and fully explanatory. A Vine exhibited in a pot with all its roots outside would not have been in defiance of the words of the Worksop schedule. However, common sense should have pointed out the intention of the words. And now, let bygones be bygones—they shall be so far as our columns can render them so.—EDS. J. of H.]

POMOLOGICAL GLEANINGS.

PEARS FROM ORCHARD-HOUSES.—At the Crystal Palace Show, September 4th, in the first class of Pears for flavour were *Burré d'Ananias* and *Louise Bonne* of Jersey, both sorts understood to be orchard-house fruit. At the meeting of the Fruit Committee of the Royal Horticultural Society, September 10th, George F. Wilson, Esq., sent a dish of magnificent *Louise Bonne* of Jersey Pears, among the largest ever seen of that variety; they were grown in pots in an orchard-house, but moved out of doors during the summer months. The flesh was very tender, melting, and juicy, and the flavour delicious. The question agitated by some unskillful growers that Pears cannot be cultivated with success in orchard-houses seems disposed of.—AN AMATEUR.

MELON APPLE.—The largest specimen of this fine fruit we have ever seen has been sent to us by George Wilson, Esq., of Gishurst Cottage, Weybridge. It measured $14\frac{1}{2}$ inches in circumference, $\frac{3}{4}$ inches across, and was $4\frac{1}{2}$ inches high. The shape was more conical than we have been accustomed to see the fruit; but in regard of flavour there was not the slightest difference from what we have always found it. The flesh was quite tender, and the flavour delicate and excellent. The fruit is more remarkable from the fact that it was grown in a pot. The crop was set in an orchard-house, and ripened out of doors.

NEW LATE PEACH.—We have had submitted to us one of the largest and best late Peaches with which we are acquainted. It was received from Mr. Rivers, of Sawbridgeworth, and is called *Pêche du Teissier*. It measures $10\frac{1}{2}$ inches in circumference, is of a remarkable shape, being somewhat pinched in towards the stalk in the way of a Quince, and very much flattened laterally; the suture is very marked both on the crown and on the side. The skin is pale green, with dull red on one side, and with

black streaks of red somewhat resembling *Late Admirable*. The flesh is very melting and richly flavoured, with a deep dark stain of red round the stone.

KEEPING FILBERTS.—We have within these few days had a parcel of the *Kentish* or *Lambert Filberts* submitted to us, which have been preserved for four years, and which are now as fresh and fit for use as they were the first season they were gathered. They were grown by Mrs. Wilson, of The Grange, Worth, Sussex, and preserved simply in jars, in which they were packed close, and kept in the wine-cellar. The nuts were quite sound, and the kernels perfectly plump and sweet.

COMMON PLANTS WITH REMARKABLE OR ORNAMENTAL FOLIAGE.

(Continued from page 8.)

ALTHOUGH botany as a science, taken in its most comprehensive sense, has certainly been for some years on the decline, still sections of that science receive their due meed of attention in accordance with the taste public opinion takes in the matter. Some years ago Orchids were all the rage, and most of these were distinct species (not garden varieties) requiring a botanical nomenclature to a certain extent descriptive of the plant, and thereby conveying a little information on the science. Then, again, we have had the extensive *Pinus* family forming distinct genera and species, mostly all dignified with names expected to be persistent. These two sections of the vegetable family have been followed by a third, which promises by the long array of hard names by which it announces itself to be as extensive a group as either of the others, and still more a botanical class in the fullest sense of the words. It is needless to say the section now alluded to is Fern, which for the variety of forms it takes, as well as the extensive range of climate its members belong to, is certainly deserving the attention it receives at the hands of its most devoted admirers, and much more than it usually receives from the general mass of the public. But it is not for the peculiar merits of the Fern that I now call attention, graceful as all the family are, but merely to point out that there is in reality beauty in other plants as well, which the stirring impulses of poetry have not deigned to notice, and, consequently, their neglect. But as the fashion for fine-foliated plants will after awhile, doubtless, descend into humble, and what may, perhaps, now be regarded as vulgar matters, and as the foliage of plants suitable to embellish a nosegay, bouquet, wreath, or other fanciful decoration, or the plant itself may be useful in some other ornamental way as a whole, I will here mention a few merely as a nucleus for others to be added to; and if their extreme commonness gives offence to the fastidious flower-gardener or the ardent admirer of Ferns and exotics, I can only ask him to examine the plants I mention either closely, or notice them at the distances indicated, and he will see that true beauty is obtained in other forms than in the much-divided leaf of a *Lastræa* or an *Adiantum*, handsome as these plants doubtless are. But Nature presents her beauties in other and more varied forms as well as these; and I hope the short list I here give will receive augmentation from other quarters, as the subject is one well worth general attention.

CANNABIS GIGANTEA.—This is a large form of the common Hemp, and grows 6 feet or more high, with a beautifully pinnated leaf, clustered in a sort of fan-like form at the top of every branchlet, which are pretty numerous but not crowded. The whole aspect of the plant is oriental, reminding one of the Palms we are in the habit of associating with eastern scenery. As a plant nothing is more easily grown. Seed sown in March with other annuals in a gentle heat, and afterwards planted out in May, quickly shows the neatly furrowed character of the leaflets and the general outline of the plants. I believe there are some other varieties, and possibly some one will be presenting us with one by-and-by having the rich claret-coloured foliage of the purple spicant with its own inimitable graceful form. That such may be I have no doubt; only let public taste intimate its wants, and caterers for it will accomplish much at one time thought impossible.

INDIAN CORN OR MAIZE.—This, I believe, to be more generally known than the last named, and differs widely from it in all its features; and its appearance is more striking when viewed some 50 yards or more off than when examined close at hand. Nevertheless, its graceful foliage in a half-furrowed, half-

curved condition gives it a form at once pleasing and yet tropical, while the terminal spikes of male blossoms are in themselves interesting, though not possessing the high colouring required in flower gardening of the present day; but grown at the back of a mixed herbaceous border, or, what is better, at the opposite side of a piece of water or impassable gulf, it stands out in bold outline to the many plants with which it may be grouped. It is, however, advisable to say that it requires shelter, high winds breaking the foliage. A warm situation and warm summer are also wanting to bring it to perfection; but it will thrive and look well under ordinary treatment.—J. ROBSON.

(To be continued.)

SUCCESSFUL FLOWER-BEDS.

HAVING read the invitation in your Journal to send a description of our pet bed for the season, I send you the same of my pet which I leave to you to judge the worth of.

The bed is an oval, 18 feet by 9 feet, a two-year-old *Canna indica* in the centre, then six two-year-old Flower of the Day, three on each side the *Canna*, then a row of *Perilla*, then three rows of Flower of the Day, autumn struck, edged with *Lobelia speciosa* from seed. This is my pet, every plant having done its duty without an exception, and the bed graduates from the centre on all sides. The *Lobelia* I had about this time last year, but did not sow it till the spring, and first-rate it was; but I have seen some from the same seedman that was obtained in the spring that grew so straggling and coarse that it was pulled up, being more an eyesore than ornament. Is this caused by the soil?

Will you please say how an oval bed, 14 feet by 7 feet, will look with amplexicaulis *Caleolaria* in the centre, Purple King round that, and Mangles' Variegated for an edging? I have seen, too, the notes for and against the Variegated *Geraniums* out in beds. I do not pretend to judge them myself, but I have just seen a little part of a garden planted with them entirely, each kind in a bed by itself, such as Mountain of Light, Alma, Countess of Warwick, Mrs. Lennox, Golden Chain, Iry Cup Leaf, and Silver Queen, and they look as fresh as they did at Midsummer. Whilst *Caleolarias* and Scarlet *Geraniums* have been cut to pieces by the heavy rain, they look all the better for the washing. The same with my pet, the *Lobelia* not suffering from the rain like other things.—SCRIBBLER.

[You are quite right, Variegated *Geraniums* are invaluable in flower gardening. Your pet bed, for instance, is entirely of one kind of Variegated *Geraniums*, and two neutral plants—the *Canna* and *Perilla*.

Your proposed bed of amplexicaulis *Caleolaria*, kept in its proper place by the upright Purple King Verbena, and the edge of Mangles' will be charming to look at; but put two rows of Purple King close together to make the belt thicker and more strong; also, two rows of Mangles', but do not train it close so as to look like a steel chain round a bull dog's neck, as some do it. If you keep it even on the two sides, it is all the training that Mangles' ever should get. Did you never hear or notice that a whole bed of Mangles' Variegated makes the best telling bed of all the Variegated *Geraniums*? Such a bed needs only the longest and strongest points of the plants to be stopped and the sides kept cut to the shape of the bed.]

THE SUCCESS OF GARDENER SPRUCE.

THE key to his success is this: He makes gardening a science, reduces principle to practice, matures his plans beforehand, and carries through whatever he undertakes.

To aid him in his endeavours, Gardener Spruce in his earlier days adopted the following valuable maxims as his guide:—

1. I will perform every operation in the proper time.
2. I will perform every operation in the best manner.
3. I will finish every part of an operation as I proceed.
4. I will complete one undertaking before I begin another.
5. I will always leave my work and tools in an orderly manner.
6. I will clean every tool when I leave off work.
7. I will return every tool and implement to its proper place at night.
8. In general—I will have a place for everything, and everything in its place.

Gardener Spruce is emphatically a "law and order" man,

and in being such has acquired what every tiller of the soil has not—namely, the reputation of being a neat and successful gardener. Let others do likewise.—(Genesee Farmer).

ENTOMOLOGICAL SOCIETY'S MEETING.

THE September Meeting of the Entomological Society was well attended, and a number of interesting and new species of insects were exhibited by various members, notwithstanding the remarkable scarcity of insects in general during the present season.

Mr. Samuel Stevens exhibited two splendid specimens of a new Goliath Beetle, *Dicranorhina Layardi*, closely allied to *D. Derbyana*, taken on the borders of Lake N'gami, in Central Africa by Mr. Layard. Also a new species of *Paussida*, allied to *Platyrhopalus denticornis*, taken at Rangoon, in the East Indies. He also distributed among the members a number of specimens of the rare Beetle, *Triplax russica*, which he had reared from the larvæ found in a fungus upon an Ash tree.

Mr. Stainton exhibited a specimen of one of the Noctuidæ, *Nonagra Elymi*, recently described in this country for the first time, which had also been captured at Stettin, in Prussia.

The President, J. W. Douglas, Esq., exhibited a beautiful Moth, *Orodessa apicina*, which had been taken alive in the London Docks, having been imported from Porto Rico in a vessel.

Dr. Knaggs exhibited two species of Caddice Flies new to this country—*Agrypnia picta*, from Skiddaw, and *Leptocecus fulvus*, captured at Ruislip, Middlesex.

Mr. Scott also exhibited four species of Hæmiptera, new to this country.

The Rev. F. Orpen Morris exhibited a remarkable specimen of *Lasiocampa quereus*, having the antennæ much shorter than in the normal condition of the species.

Mr. Frederick Bond exhibited specimens of two very rare British Moths, *Lithosia canoala*, and *Dianthæcia capsophila*. And Dr. Knaggs a specimen of a species of Noctuidæ new to these islands from Ireland.

A case of beautiful insects, captured at Dacca, in the East Indies, containing many rare species, was exhibited by Mr. Brettingham.

The Secretary, Mr. Edwin Shepherd, read a second communication from Lord Dunsany on the ravages upon the foliage of Ash and Lime trees in Dunsany Park, Ireland, committed by myriads of the larvæ of one of the Geometridæ, *Biston hirtarius*. The trees were rendered completely leafless, after which vast numbers of the caterpillars were found crawling upon the adjacent walls.

Mr. Francis Walker read some notes on the habits of various insects, including *Chlorops tarsatus*, a little Fly found in vast numbers on the roofs of apartments exposed to gardens and fields at this season of the year; also on several species of parasitic Hymenoptera.

WORK FOR THE WEEK.

KITCHEN GARDEN.

TAKE advantage of favourable mornings for wheeling out old hotbeds and other manures on spare ground, and for getting the ground well trenched and roughly ridged to receive the beneficial influence of the atmosphere. *Asparagus*, when the tops are decayed cut them off close to the ground. The beds to be then cleaned, and afterwards covered with 3 inches of rotten dung or leaves. The alleys to remain as they are, not dug out, as by so doing many of the roots are injured. *Broccoli*, the Cape sorts and Cauliflowers now forming their heads to be protected from frost by covering them with a few of the under leaves, or by breaking down the heart leaves on the head which is forming. Where it is growing very strong it is advisable to dig it up and lay it in trenches in nearly a horizontal position, covering the roots and stems up to the leaves. This has the effect of checking luxuriant growth, and of protecting the hearts of the plants in severe weather. *Brussels Sprouts*, those who grow tall varieties should take off a few of the lower leaves as they become ripe, to encourage the sprouts. *Cabbage*, the quarters planted to be searched for slugs and grubs, and any blanks that occur to be filled up without delay. Those planted out in August for Coleworts to be earthed up. *Endive*, by placing 3 inches or 4 inches of sand on the floor of the fruit-room, vegetable-shed or cellar,

and taking up some plants with balls of earth about once a-week in succession and placing them in the sand, where it will blanch beautifully without further trouble. *Lettuce*, continue to plant the Cabbage varieties into frames for winter use. The *Cos* varieties for spring use should also be planted on a shallow border as soon as they are of sufficient size. *Sea-kale*, gather seed when ripe, and as soon as the leaves begin to decay clear them away. It is necessary to do this as early as possible where it is required for early forcing. *Turnips*, thin the late sowing; but it is not necessary to leave them to so great a distance apart as the spring and early summer sowings. Take every favourable opportunity of clearing the ground from weeds. In many of the best-kept gardens they are troublesome at this season when the ground is usually too wet for hoeing and raking; but these are more especially so where they have been allowed to seed during the summer.

FLOWER GARDEN.

Some spare beds should now be prepared for the reception of Hyacinths, Tulips, Crocuses, Narcissus, Snowdrops, and other such early-flowering bulbs. Crown Imperials, hardy Lilies, bulbous Irises, &c., should now be planted in the borders. Ornamental shrubs, whether evergreen or deciduous, may be removed with every chance of success. No hesitation need take place as to the kinds, provided the ground is properly prepared by trenching, and thoroughly devoid of stagnant water.

FRUIT GARDEN.

The principal operations in this department are the gathering in of the fruit as it becomes in proper condition; making preparations for filling up blank spaces, and trenching ground for orchards and fruit plantations, which should be well done to insure success. Continue to keep the runners removed from the Strawberry plantations; and those that have been some time potted for forcing to be placed in a comfortable situation that they may not get too much soddened with wet. Strong prickled plants may still be potted with good success if placed on a kindly bottom heat.

STOVE.

Forcing must be avoided as much as possible: nevertheless, the cold nights must not be allowed to reduce the temperature so as to check prematurely the declining growth.

FORCING-PIT.

Get in an ample supply of all kinds of shrubs fit for this purpose, pot them and plunge them in old tan. This will apply more especially to American plants. All kinds of Dutch bulbs, if not already done, to be immediately potted and plunged in a convenient situation ready to be removed when wanted to the forcing-pit. Lily of the Valley to be potted for the same purpose. Mignonette to be protected from rain and frost, and when advanced sufficiently they may be placed in the forcing-pit to bring them into bloom.

GREENHOUSE AND CONSERVATORY.

In these structures many summer-flowering plants must now be cleared out to make room for early-blooming Camellias, Scarlet and other Geraniums, Cinerarias, Gesnera zebrina, Primula sinensis, Neapolitan and Russian Violets. See that Epacris are placed in a light part of the house where they will be freely exposed to the sun so as to get the wood well ripened to insure their blooming freely. Examine Heaths or anything else subject to mildew frequently, and apply sulphur immediately the pest can be seen. Any of the late-growing sorts which may be in want of more pot room may still be shifted, but do not expose them to cold winds, and water them, as also the large plants, very carefully, for the roots cannot be expected to progress very rapidly at this season. Take care that the Chrysanthemums are placed near the glass and well supplied with manure water, air to be given to them freely, as anything like close confinement would seriously damage them.

PITS AND FRAMES.

Presuming that all the tender stock of plants is safely housed, and anxiety about the future considerably diminished, proceed with the arranging and removing into any spare cold pits the stock of Pentstemons, Antirrhinums, Linums, Phloxes, Brompton, Intermediate, and other Stocks, and all herbaceous plants in pots that require a little protection. The pots to be plunged in sand or coal ashes, which are both a protection and save much labour in watering during the spring months. If cuttings are now taken from Chrysanthemums showing bloom, put singly

into small pots, and placed in a gentle heat, they will soon root and bloom beautifully for decorating fronts of stages or any other place where dwarf specimens may be required. All cuttings that are now required must have more heat and air to prevent damping off.

W. KEANE.

DOINGS OF THE LAST WEEK.

GENERALITIES—CHARRING.

COLLECTED all the refuse, prunings, and topplings during the summer into one heap, to be covered with turf and earth and charred as soon as a chance offers, when the smoke will not be annoying. In large places this work can be done at any time, but in small places, and where the kitchen garden is near the mansion, fit times should be chosen for all such work, as nothing is more annoying than the smoke from a rubbish, smouldering, or charring-heap, when it is wafted against the windows of living-rooms. The direction of the wind, therefore, should be watched, and if the family should be absent for a day or two, then is the chance. Our next heap will be made up of mere prunings, Hollyhock-stalks, &c., and things of that kind. Dahlias and other herbaceous plants are generally more fitted for rotting into compost than charring. In charring such prunings, &c., the chief thing is to get them as closely packed as possible, and covered before setting fire to them. If the fire is lighted in the morning, and a few holes left near the top for the smoke, the heap will generally be brought down to manageable dimensions before night. But if the heap is large, it will be sound economy to employ a man to watch it for two or three nights, to prevent the flame finding a vent, for whenever that is the case you will be rewarded with white ashes instead of charred material, so useful for seed-sowing, cutting-striking, and all the rest of it. In managing such heaps, light where you will, the fire will take possession of the top of the heap, and, therefore, the air-holes, to keep up a smouldering, charring combustion, must be made round the top. As soon as you find, by inserting a crowbar, that the material at the top is charred, the holes there must be stopped securely, and a row made all round farther down, and so on, until the bottom of the heap is reached, which will be the last to be charred. We frequently mix sawdust with such heaps, and thus get it charred nicely; but we never attempted it by itself without finding that the trouble exceeded the profit.

RAKING.

But for the longer nights and the heavy dews, we should be obliged to sing out for the want of water. The fields are very dry, and the tanks low; but little watering is wanted now. No better chance could be had for giving the weeds a scuttling; but though the days are hot, the weeds do not flag up very quickly, owing to the heavy dews at night. We seldom allow rakes to be seen on our grounds, but we have scuffled some ground with them after hoeing. Except for the very outside of a flower-bed, and that for the sake of levelling with the head of the rake more than for using the teeth, I would as soon see a donkey in a flower-border as a rake. The one, in general, would do less damage than the other. There is no end to the injury which the teeth of a rake may do under such circumstances, especially when a man would rather play with such teeth round a plant instead of stooping and doing what was wanted with the best rake that ever was invented—his own good fingers. When we want plants to fill their allotted space, we have no notion of dressing the ground until the surface is as hard as a gridiron.

COLLECTING TURF AND EARTH.

We got a little from the sides of a road, but the supply was limited. A small group of trees having to be planted in the park, and to be filled up with under cover, it was found that the turf would be in the way, and we were glad to take a thin paring, though not of the colour nor the consistence we chiefly value. In these days we must often cut our garment according to our cloth, and any garment after all is better than none. This turf we build in narrow stacks $3\frac{1}{2}$ feet wide, and some 6 feet high to the ridge. The ridge may rise from the level about 2 $\frac{1}{2}$ feet on each side. Most likely we shall fasten some turf, grass upwards, on each side of the ridge, but we find if well beaten little water penetrates, even if the ridge has no covering whatever. Such narrow stacks built with turf containing some portion of rough grass, will allow the air to pass through them pretty freely, and thus become sweet and partly decomposed without

any undue waste of the fibre, so that when used the compost will be porous and open. It is easy to give it consistence enough by ramming when wanted. Such heaps thus get sweet without turning, and it is a great advantage every way when they can be piled up dry. I should have liked better if the grass, instead of being rather broad-leaved, had been small and sharp like so many needles and pins.

KITCHEN GARDEN.

Notwithstanding the dry weather the Cabbage plants that succeeded the Onions have grown amazingly—almost too much in fact, for the stronger they get the more apt will they be to suffer from frost. Another planting, therefore, will be advisable after the middle of the month, and if the first stand well there will be no necessity for keeping the second, if ground is valuable and scarce. Pricked out Brown Cos, Hammersmith, and brown Cabbage Lettuces, at the foot of walls, and will, ere long, put some thickly under protection, in case the weather should be severe. Hoed and stirred the earth about Lettuces and Endive in turf pits, where they will receive protection in winter. Turned out some hand-glasses on an open space of ground, so as to fill them partly with Cauliflowers sown at the beginning of September, and others sown after the second week, as sometimes the first are apt to blight prematurely. We generally put nine plants in a hand-light, and in March single them out to four to each light. We thus generally get them early by using a little protection in spring, and giving protection in winter only after the plants and ground are slightly frosted. We shall pot also some hundred plants of the last sowing, giving each a 60-sized pot, keeping them on the floor of a cold house in winter, giving them a five-inch pot in February, and turning out into fine, rich ground at the middle or end of March. These sometimes beat those under hand-lights, but in general there is little to choose between them; but it is as well to have two chances instead of one. Will prick out a lot a few inches apart under glass in a frame ere long, and a number more out of doors by the side of a wall. When planting under glasses and in a frame, we cover the ground with an inch or more of rough sand, which is not only a little protection against slugs, but keeps the stems free from rot and spots, because keeping them dry, and is also so far a protection against frost. I picked up this move from an old gardener in a small place, when I was a school-boy, and thinking nothing about Cauliflowers then. I recollect the old gentleman saying, "They may well let me have a few Cucumber and Melon plants, for they come to me every spring for Cauliflowers. It is no use telling them why their's fail, they would only laugh at me and my sand; but look there!" And sure enough not a plant was diseased, or a solitary instance of a failure.

MUSHROOM-BEDS.

Swept over and fresh covered Mushroom-beds. Wanting a quantity for a certain purpose, we covered the earliest bed in the house with wheat straw; and though we got plenty of Mushrooms, we found that the straw, as we had often found before, was apt to pull off and unsettle the little ones we wished to grow on; but we could not help ourselves at the time. Now a slight dusting with hay remedies all the inconveniences. When the beds are bearing in winter, and artificial heat used, the covering of the beds is of little consequence; but at this season it tends to keep the beds moist and cool on hot days, and close and warm on cold days. We find that the Mushrooms always come quicker with a little covering on the surface, provided the surface is kept firm, smooth, and clean. A good part of the new-spawned bricks have been removed, the making and management of which were previously described, and the autumn being so warm the heap required nothing more to cause the spawn to run freely than being surrounded by dry litter. Gathered a quantity of Chilis and Capsicums fully ripe, to be dried and ground for cayenne, as little dependance can be placed on the cayenne generally sold. The fruit on the plants will ripen all the better from being relieved of the fruit that was ripe.

PROPAGATING BEDDING PLANTS.

In the fruit garden, much the same routine as last week, with the exception of gathering some Apples and Pears, that are scanty indeed this season. In propagating, we have hitherto used no artificial heat. As we could not well get all we wanted without breaking in upon the symmetry of the beds, the most of what we take off now will be placed in small pots thickly—the base of the cutting close to the sides of the pot, and the

heads leaning inwards, and placing only one row all round the sides of the pot rather thickly; and these we will give a mild heat to by taking off the soil from Melon-beds, forking over the manure-beds, and placing a little fresh heating material in the bottom of the trench as we go along. The old manure will, therefore, be still at the surface, and be rather dry than otherwise. A few ashes will be placed on the top to plunge or half plunge the pots in, and air will be left on at night, and very often a little all day; a little shading being given in bright sunshine only. The air here, and merely a mild heat, are the valves of safety. We always recommend all such cuttings to be struck cool before the middle or end of September. After October has set in, however, we should sooner depend upon such a plan for general things than bother taking up and trying to keep old plants. In such a place Verbenas, washed well to clear off thrips, will be struck in ten days, and then should have more air. Scarlet Geraniums are almost the only things worth taking up, unless it be large plants of other things for standards. Even they will strike well in such a place during this month, and will require little room in winter. We should except Calceolarias, they will do better in the cool on a firm surface and a porous bottom. The middle of October is the best time for inserting the cuttings, provided frost does not come previously.—R. F.

TRADE LISTS RECEIVED.

A Descriptive Catalogue of Fruits, by Thomas Rivers, Sawbridgeworth.—Most of our readers are already familiar with this excellent catalogue, the new edition of which, this year, has undergone revision, and received several additions, particularly in the list of Grapes.

A Descriptive Catalogue of Selected Roses, by Thomas Rivers, Sawbridgeworth, is a very good and well-selected catalogue.

Charles Turner's Catalogue of Fruit Trees, Roses, Conifers, Hardy Trees and Shrubs, &c., Slovjgh and Silt Hill, near Windsor.—This is a very useful catalogue for those who wish to have the best kinds of the plants it contains, the selection being good and judicious.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications.

We cannot reply privately to any communication unless under very special circumstances.

WINTERING GERANIUMS (*J. L. M.*).—Drying bedding Geraniums, or keeping them in a dry state over the winter, is one of the oldest plans, and under some circumstances it is the best plan. Mr. Beaton has gone so fully into the subject of wintering Geraniums to-day, that we have nothing to add.

EVERGREEN ENGINES.—PLANTING OUT DABLIAS (*A Young Amateur*).—"Is there any evergreen suitable for a border in addition to Box?" On peaty soil, common Heath; on other soils Thrift, Saxifraga hypnoides, and turf. The Dablias you name are hardly enough to be planted out, not only by the 10th of May, but just one month sooner, the 10th of April, provided you have the tubers now, and can keep them over the winter. We always plant our Dahlia tubers just like Potatoes, and as soon as the Potato planting is finished in the spring we prepare for planting the Dablias before they begin to sprout, or very soon after, and that saves nine-tenths of the trouble which some people usually take with Dablias. Their tubers are quite as hardy as Potatoes, and they may be as safely trusted to the earth quite as early in the spring as Potatoes.

DODDER (*Old Bond Street*).—The plant which is infesting your Lucern is *Cuscuta Trifolii*, one of the Dodders, a parasite which will overrun the whole crop if it is not arrested. It comes from seed, but so soon as its stem has fixed itself to a plant of Lucern, the stem emits suckers, which rob the Lucern of its sap. It is said that the only remedy is to grub up the whole crop and burn it before the Dodder ripens its seed; but we should like as soon as the Dodder stem has decayed from its root, after establishing itself on the Lucern, to have the latter all mown and consumed in some way. The Dodder not having seeded we think the next cut of Lucern would be free from the parasite.

FRUIT-GATHERERS (*A Constant Subscriber, Worthing*).—Apply to Mr. Riddell Cross Hall Chambers, Bishopsgate Street, London, E.C.

PRIMULAS SHORT-STALKED (*Primula*).—We do not think there is anything the matter with your *Primula* plants. Plants *n* are apt to be short-stalked; but the reason of that is, obviously, enough in all plants not firmly established in their pots. If you nick off your pots at the bottom, use rather small pots instead of large one, so that the pots will be full of root; the flower-stems will then, we presume, get high enough to please you; therefore in this case the seed-men, we presume, are not to blame. As to the other case, you should have complained to the tradesman. It is not impossible that your tuber might have been tampered with. Certainly we should prefer a sound whole tuber, though smaller, to one cut about in the way you describe. But you should have complained to the party.

RAISING APPLE TREES FROM CUTTINGS (*A Subscriber*).—There is no doubt that not only the Ribston Pippin but all other Apple trees could be propagated by cuttings, if treated in the same way as are the cuttings of other hard-wooded plants. The Bur-knot, the Codlins, and the Joaze cutting are the most easily so propagated, so far as is known. See what is said in our paper to-day about propagating *Firm trees* by cuttings.

MAKING A VINE-FORMER—STOVE OR HEATING (*A Subscriber, Dublin*).—We think your border will be a great deal too rich, even without the sacks of superphosphate and the butcher's blood, especially for roses to be forced early. We should prefer giving the superphosphate a top-dressing if the Vines were not strong enough afterwards. We should say make your border three-quarters of good turfy soil, with fresh but sweet soil to plant in, half of a port lime rubbish, and the other half bones and dung, but chiefly bones. This, with good drainage, will grow fine-flavoured Grapes. You may add a little peat, but you prefer size to quality, but chiefly on the surface. The kinds mentioned are very good down to Black Fries. We do not know Gros Colman or Rue de Margenta. Gros Maroc, Muscat St. Laurent, and Chaptal, are said to be the new Vines of excellent quality; the Muscat growing like a Cascade, but with something of the flavour of a Frontignan. We have no doubt of your arrangements for a top-dressing, or a small lean-to vinery, 20 feet by 11 feet, an iron stove, or, better still, a small brick stove, will keep out frost; but until you are up to the management you must not attempt to force much. Cannot you detect why the rose will not heat properly, and thus account for all this bother. We have scarcely met with a time that we could not make work with a little alteration, if the alteration was possible. You would see this spring that Mr. Rivers forced a house of *Roses* double your size with an Arnot's brick stove. Really the Rue if you can. If the bars of the grate are 18 inches high, the bottom of the grate is 18 inches above the floor, from the furnace to the chimney, it can scarcely help itself—it must draw. We should have liked the ventilators in the back wall to be nearer the top than 2 feet from it; however, if you have plenty of them it may do without opening the top sashes. We can say nothing satisfactory, as we know neither the size of the house, or the size of the ventilators. In the common vinery you would need no ventilation low down. In orchard-houses sub-ventilation is desirable.

FLOWERS AT CHRISTMAS IN A GREENHOUSE (*Inquirer*).—Retarded *Chrysanthemums* and such plants as *Saxifraga*, *Scarlet Geraniums* of different colours, kept rather dry, *Chinese Prim-roses*, *Neapolitan* and other *Violets*, and *Camellia*, will do very well in a greenhouse, if you get full of roots, and also *Camellia* with forward buds will bloom in such a house; and *Eranthis*, *Cytisus*, and many other things could be brought in, if more heat was used.

VINES IN POTS (*Agona*).—We are complimented by you thinking that we have set at rest the question as to what is growing Grapes in pots? The subject need not be discussed further, and we must say to you, Mr. Bennett, like others before him, was quite entitled to plead that he acted up to the words of the Society's rule. As we said last week, the rule should be more unmistakably worded. In saying this, we do not differ from the Judges' decision. They decided quite correctly.

CRUCIFERUS TOMENTOSA AS AN FRUING (*E. P.*).—Last week, and the week previously, we gave directions for its propagation. It is quite hardy and only requires to be propagated every spring, planting the divided pieces where the edging is to be.

NAMES OF INSECTS (*P. A.*).—The maggots which infest the Mangold Wurtzel leaves, feeding upon the parenchyma or inner substance of the leaves, are the young of a fly scarcely distinguishable from the common house fly. They go into the ground to undergo their transformations, and those in the spinach leaves are the larvae of a closely allied species. Hand-picking is the only remedy.—W.

DISEASES IN FIRM TREES (*A Constant Reader*).—The young shoots are infested with the common *Hydium piniperda*, a Beetle allied to the family of the Weevils, and the shoots should be picked off as soon as they show the least sign of being injured, and be burnt immediately.

ASPHALTE (*M. A.*).—It would do very well for flooring a greenhouse. It is made of lime rubbish two parts, and coal ashes one part, both very dry and sifted fine. In a dry place and during dry weather, mix it with boiling-hot coal tar into a mass as thick as mortar, put it 3 inches thick to form the floor; sprinkle over it coarse, dry sand, and when cold pass a light roller over it.

SUPERPHOSPHATE OF LIME—SULPHATE OF AMMONIA (*W. Adams*).—About 5 cwt. of the first and 2 cwt. of the second per acre, is an average quantity to apply to your light land grass. Apply them in the spring. We should sow them broadcast over the surface during wet weather. Apply to the artificial manure companies for other information.

ORCHARD-HOUSE (*M.*).—The eastern aspect will do, as we presume the soil and wind would be exposed to the west. There is no paper devoted to market gardening. We gave up publishing the market prices as we found that they only misled. The retail prices afford no criterion whereby a seller can calculate what would be realised.

LILIUM GIGANTEUM NOT FLOWERING (*Kate*).—If kept dry all the winter, the *Lilium* in your greenhouse may do well enough next spring; but all things considered, unless this can be done, we would report it carefully, and keep it in a cold frame from frost, and in a warm one in a hot frame, and just seeing that the roots do not suffer from dryness. When it commenced growing next season, we would set the plant on moist kept moist, or in a saucer, with half an inch of water in it, in preference to watering much on the surface until growing freely.

EXCLUDING WASTES FROM GRATES (*A Constant Subscriber*).—The best plan is to use soft glazed thin muslin made into bags. The bags will stand

out from the bunch, and allow light and air to get to the berries. It must be tied tight at the stalk. If it will not go quite close, stick in some cotton wadding with the woolly part out. We have also used bags of fine silk paper, but that is not equal to the muslin. A dining fellow will make a way for himself, and then myriads will follow. The waste are getting thin now. If you could drive them all out of the house, you might cover the ventilators with gauze.

VINES AND FLOWERS (*S. L., Clarendon Villa*).—Prune your Vines as you propose, at the end of this month. Cut them back to 1 foot or 15 inches from the bottom of the vinery. The ensuing summer will pay you good interest afterwards. In winter you may have bulbs, elsewhere forced, brought into the vinery. *Eperis*, *Camellias*, *Coronillas*, *Primroses*, *Violets*, and *Cinerarias*, &c., without any forcing, in bloom most of the winter with a temperature never about 15° with fire heat. If you go above that you will start your Vines prematurely. With the exception of *Scarlet Geraniums*, hardly any bedding plants are worth taking up, as young plants will thrive better and take less room. *Geraniums* may be potted and kept growing in a cool, shady place. To merely keep old *Scarlets* take them up, shorten them, remove one leaf, and pack them closely in the pots or boxes. Keep your bedding plants in the coldest end of the house. Suppose you take up a *Calceolaria* or a *Verbenia*, you would need a four-inch or five-inch pot, and you might have a score of young ones in that space.

NAME OF FRUIT (*Fairfield*).—Your Apple is the summer Golden Pippin.

NAMES OF PLANTS (*W. Smith*).—1. *Podium vulgare*; 2. *Pteris longifolia*; 3. *Polypodium dryopteris*; 4. *Blechnum occidentale*, var. minor. (*Fanny*).—*Adiantum formosum*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

JUDGING POULTRY.

As a constant reader of your useful paper, I have been much interested in the published opinions on the subject of judging, which have appeared from time to time; and, especially so in your remarks in last week's Number on the suggestions of "T. B." for the establishment of a new system of awarding the prizes at exhibitions. You have gone so fully into the subject that there is but little left for myself or any one else to comment upon; but I trouble you with a few lines as you express the hope "that opinions may be elicited from your readers." From my experience of twenty years as a breeder and exhibitor, and lately as judge, I do not believe it possible to carry out into practice the suggestions of "T. B.;" the expense attending the engagement of "a number" of poultry amateurs would be an objection *in limine*. Every one knows how difficult it is to make both ends meet in the accounts of poultry exhibitions; and if committees are to undertake the "out of pocket" expenses of "a number" of gentlemen from various parts of the country, and pay the usual Judges as well as act as arbiters, I fear they will need in the first instance materially to increase their subscription list to enable them to meet this extra expense; and further, I very much doubt whether our best Judges would like to be tied down to a selection of pens from amongst those marked by these amateur gentlemen. Their experience and their judgment are necessarily so much more extended and perfect than can be the case with exhibitors who never act as judges, that I am persuaded, if a poll could be taken, at least nine exhibitors out of ten would vote for the engagement of two or three of the best judges who could be obtained, rather than adopt the intricate and expensive plan suggested by your correspondent. I entirely agree with you that as a rule "poultry shows are well and honourably conducted;" and that the exceptions are so rare (if exceptions there be), as should lead exhibitors to pause and reflect whether the mistake may not arise in their own opinions rather than be traceable to unfairness on the part of the Judges.

I do not like to trespass upon your space further, as doubtless others may have something to say; so I will conclude by remarking that it is in the interest of all parties that correct decisions should be arrived at in awarding the prizes, and my firm conviction that none but those who have had large experience as breeders and exhibitors of every variety are competent to award the prizes satisfactorily. The character and reputation of the Judges, the credit of the Committee, and the satisfaction of the exhibitors, alike combine their influence towards a right decision; and I believe in the great majority of instances this right decision is arrived at.—C. BALLANCE, *Taunton*.

If readers judge from some of the eulogiums which appear occasionally in the columns of THE JOURNAL OF HORTICULTURE and elsewhere, they would most certainly imagine that the office of judgeship of poultry shows is both lucrative and agreeable. The former is decidedly not, and the latter but seldom; as but few shows pass off at which there is not some disappointed and riled exhibitor more ready to attribute his want of success

to the ignorance or dishonesty of the unfortunate judge than to any fault of his birds or his own want of judgment in matching them. He therefore, in the first place, bursts forth into a torrent of rage; but fortunately he has not the power to vent it personally on the Judge, as he has left the show-room and leaves the town by next train. He therefore resolves to write, and does, and such a letter—one which would not convey a favourable impression either of his conduct or temper. And why is this? Simply because this gentleman, who is an acknowledged good judge, was of opinion that one exhibitor's birds were better than another, and therefore with all honourable intentions awards the prize accordingly; and for this he is to be abused worse than any swell-mobman! This is one of the pleasures of poultry judging. Another is having to travel perhaps two or three hundred miles to and from the show, work hard for a whole day, and afterwards perhaps not to get his expenses paid. How much better would it have been for this impatient exhibitor if he had written to the Judge in a gentlemanly and courteous manner, asked an explanation of his awards, which he no doubt would willingly have given him. He would then, probably, have been able to improve his pen, and the next show be a successful instead of a disappointed exhibitor.

I mention these particulars merely to show that it is a mistaken notion to suppose that poultry judging is such a sincere as some seem to imagine.

I am induced to intrude myself upon your columns, having seen a letter in your paper of last week signed "T. B.," containing a proposition next to impossible to be adopted, and which if adopted would, I believe, be most unsatisfactory and inconvenient, and I do not think he need hope for one minute that it will ever be adopted.

As at the present time I am an exhibitor of poultry, also am connected with a poultry show, and am occasionally a Judge of poultry, I have had ample opportunities of observing the absurdities which appear in the shape of complaints made by exhibitors against awards. I well remember once judging a class of Game cocks; and after the awards were made and the show opened, the owner of one of the birds came to me in a most courteous manner, and calling my attention to his bird, remarked that "he thought he would have won." I then told him that he had a crooked breast, which on handling he found to be correct, and was perfectly satisfied. I mention this incident to prove, first that exhibitors are liable to make mistakes as well as Judges; and next, how much better it is for disappointed exhibitors to go to Judges, as this gentleman came to me, and ask explanation, which no doubt will be willingly given them, than to pour forth torrents of abuse upon the poor Judge, the Secretary, Committee, and poultry shows generally—and it is but seldom but that they could have an explanation of their want of success, which would amply satisfy them that the Judge was right and they were wrong. They would not lose their character as gentlemen, the Judge would not be abused as a rogue; and they, knowing the faults of their birds which shut them out of the prize list, would probably be able to remedy them by changing the birds, and, as I before said, at the next show be a successful instead of a disappointed exhibitor.

As to the query as to one judge or more, I am of opinion, after consideration and some experience, that one is best, provided that one is to be depended upon as a first-rate judge of all classes—and there are several who may be; but I think the question which has been often discussed is still open to argument, as there are *pros* and *cons* on each side. "T. B." had better get up a show, and not have the labels numbered, and see the trouble and inconvenience it would put him to. He also says, he has no doubt you will have plenty of replies, and not much variation. I think he may be right in this first-named particular, and possibly in his latter, as I shall be much surprised if all do not condemn his proposition, as well as his anonymous attack upon the judges. As I make no attack upon any one, but wish to see all have their due, I think I am justified in not publishing my name, but simply sign myself—**USTITIA**.

BEDFORDSHIRE POULTRY SHOW.

THIS Show was held in connection with the agricultural meeting for the first time on Friday last. It was but small, but there was plenty of encouragement to persevere, and there was the proof that the nucleus exists for a much larger one. Poultry has been so long neglected in agricultural districts, that

it is seldom those who have the management of these meetings know anything of the subject, and zeal is a sorry substitute for knowledge or experience. The former believes it has foreseen and remedied everything; but the latter soon teaches the valuable lesson by upsetting all theory. It is, however, astonishing how much may be learned by managing one show, and we look for large competition next year at this Meeting. We are, however, bound to state it will be from gentry, townsmen, and professional men. The agriculturists will not attend to poultry; and were it not for the love of it that is born with some people, and which causes them to try experiments and to interest themselves in every phase of the question, we should be gradually giving up the supply of our own tables with part of its most delicious food. It is quite true that the poultry shows in connection with agricultural meetings increase in number, but it is not less so that few of the entries come from the class especially interested in these meetings; and although the poultry is the most crowded part of the Show, yet it is frequented principally by the gentry and the townspeople.

This Show lasts but a few hours. It opens to the public at eleven, and is over by four o'clock. Every exhibitor is bound to provide the baskets in which his poultry is shown, and they are made according to pattern. While this insures the uniformity which is absolutely necessary, it deters some exhibitors, because they think the basket will be afterwards useless. If these shows become general, we doubt not some one will be found to provide, and let them on hire. A large lofty shed capably placed, and commanding a view of the whole of the Show, was selected for the poultry, which were ranged around about 3 feet from the ground.

The *Dorkings* contributed nearly half the Show, and were excellent in quality. If proof were needed of our assertion, we would only say the Rev. F. Thursby took first prize for adults, and first and second for chickens. It was quite refreshing to see some good rose-combed chickens shown; they deservedly had the third prize. There were excellent White *Dorkings*.

The *Cochin-Chinas* were not good in quality. It seems a pity to keep birds that are neither commendable at a show nor saleable at a market, for want of merit, when such consume quite as much food as would serve an equal number of fowls of better quality, and, consequently, twice as valuable.

There were some good *Hamburghs*; and as we suppose some of those who exhibited may look for a record of their exploits in our columns, and as we are bound to notice anything that may be of use to them hereafter, we mention the little care that was taken in the selection of some of the pens; crooked backs and faulty plumage were there. The colours of these birds should not run into an indistinct and mossy shade, but the penning should be distinct. The various breeds brought *Brahma Pootras*, *Polands*, *Sebritight*, *Game*, and *Black Bantams*. We hope to see a class for *Brahma Pootras* at every agricultural meeting where interest is taken in poultry. We are satisfied they are among our most valuable fowls; and if these meetings are to carry out their professions of being schools, trials, and lectures, then small entries at first must not be discouraged, but if it is believed that which is proposed will eventually be a benefit, the motto must be "Persevere."

Before we conclude we must mention very favourably Mrs. Ames' *Dorkings*; also those belonging to the Rev. J. G. A. Baker, and the Rev. F. Thursby's *Spauish*.

Mrs. Ames' *Aylesbury* and Mr. Thursby's *Buenos Ayrean Ducks* were perfect. The *Turkeys* and *Geese* were very good, and Mr. Leno's *Bantams* would have graced any show in England.

Mr. Baily was the Judge.

PARALYSED GAME PULETS.

I HAVE several of my Game pullets drop down on their knees. They are four months old. Is there any remedy? They look well about head and eye, but are quite paralysed in the feet; they have a good run (14 acres), and a change of diet constantly.—**F. BAILY**.

[Your Game hens are suffering from weakness or cramp induced by improper flooring of their roosting-place, or from overgrowth. If the flooring be bricks, stone, or wood, that will be the cause; if, however, it is of earth or gravel, as it should be, then it will be weakness that must be met and remedied by good and regular feeding. The reason of their dropping on their knees is, their legs are too weak to support their bodies. Feed them well on ground oats, mixed with milk, three or four

times per day, each time as much as they will eat, but no more. They must not have food always by them. It is likely if they have grown fast, they will now gain strength, and the resting on their knees is only to be overgrown in the same light as the strange positions of a lanky, overgrown boy, who looks and feels as if he would fall to pieces.]

ROUP IN PIGEONS.

I HAVE a valuable large white Trumpeter cock seized with this disease. The scale has been removed from his tongue, his tail cut a little to induce bleeding, and butter administered to act as a purgative. Is there anything more effectual I could try? Is this disease infectious? if so, should I confine the bird by himself, the cot being a large room in the loft of an out-house?—A. SUBSCRIBER.

[Keep the Pigeon clean, and free from damp or cold winds; give a little substitute of iron in the water, or smiths' forge-water to drink. Let him have such condiments as grit and broken oyster-shells, and, if convenient, let him fly out. Good wholesome food, fresh air, and the bath will often cure the roup in Pigeons.—B. P. B.]

CANARY ASTHMATIC.

I HAVE a Canary which has entirely lost his voice ever since he moulted, twelve months ago; he has been ailing ever since, and has lately become much worse. He eats all day long, and sits panting, with his feathers all ruffled. He has been in this state for several weeks. Can you tell what is the matter with him, or suggest any remedy?—INQUIRER.

[Your Canary is suffering from asthma: most likely he caught cold during his last moult. If the disease has so far advanced as to seriously affect the lungs I fear there is no cure. In the earlier stages I have found the following treatment of much benefit:—Avoid all heating and pungent seeds, as rape; give bread and milk about a thimbleful fresh every day, and plenty of green meat, as chickweed, groundsel, and lettuce; put some Stockholm tar in his water, and keep him out of the draught.—B. P. BRENT.]

THE CANARY AND THE BRITISH FINCHES.

(Concluded from page 430.)

6.—THE ORTOLAN (*Emberiza hortulana*).

German, Der Gartenammer. French, Ortolan.

The Ortolan cannot be considered as an English bird; but as great numbers are imported into this country to satisfy the cravings of the epicure, a short notice of the bird may not be out of place in these papers.

It is believed that the fashion of eating Ortolans in this country became more common during the French Revolution on account of such dainties being then prohibited in Paris. The few individuals of this species that have been captured in this country are not unlikely escaped birds that have been imported, still, as they are said to migrate as far north in summer as Sweden, it seems strange that they are not more common in England.

The following description I have endeavoured to translate from Bechstein's "Natural History of the Birds of Germany," to which excellent work I have been much indebted in the study of seed birds.

"The Ortolan is nearly as large as the Yellowhammer, though stouter in breast and beak, which latter is not so much flattened at the sides, and yellowish flesh-coloured; the irides of the eye dark brown, the eyelids are edged with deep yellow; the feet flesh-coloured, and the nails brown; the head and neck are greyish-olive; the throat and a stripe from the corner of the beak running down the neck yellow; the back and shoulders red brown, spotted with black; the rump dingy greyish-brown; the breast, belly, and vent-feathers reddish-yellow, shaded with light brown, and lighter towards the rump; the wings blackish, the primary-feathers outwardly grey, the secondaries and the covert-feathers broadly edged with red brown, so that the closed wing appears reddish-brown, spotted with black; the tail-feathers are blackish, the two outer ones having a wedge-shaped white

spot on the inner side reaching to the middle, the remainder bordered with reddish-yellow.

"The hen is rather smaller. On her head and neck the ash-grey colour more predominates, with small, oblong, black specks along the shafts of the feathers, and her breast is less brown.

"The young have previous to the first moult an undefined yellow throat, mixed with grey; their breasts and bellies are reddish-yellow, speckled with grey."

Further, "the Ortolan is a restless bird, to which day and night are the same, and it calls and sings at either time. His song has much resemblance to the Yellowhammer's, except that the voice is fuller and clearer, and also the last tone falls deeper instead of rising as in that bird."

He gives the song as *Goh, goh! peck, peck, peck, peck, peck!* *tzwit! gye, gye!*

The Ortolan is a bird of passage.

To prepare them for the gourmand they are placed in a lighted room, and well fed on oats, hempseed, and bread and milk. In a short time they become so fat as to weigh 3 ozs. They must then be killed, or they would die of fatness. They are then considered a *bon bouche*.

All the different species of Buntings are equally good to eat, and if treated in the same manner would become equally fat.—B. P. BRENT.

AGE OF BEES.

THEY say bees live only six months. Last July I added to two swarms, or rather stock, Ligurian queens. One has swarmed thrice, the other twice, and now to-day there are a very large quantity of the English bees that must be more than twelve months old. Besides which, some of these bees have been twice fumigated, and they say bees do not live the winter after fumigation; but I think when properly done it does not seem to affect them—indeed, if I may judge of two wasps' nests that I fumigated with puff-ball nitre and sulphur, and closed them up, they seem to be more lively after it, as they were hard at work next morning, and had made two fresh holes out. Driving bees, no doubt, is a better way when you want to take the queen away; but, then, bees will not always drive, and it is not any one that is clever enough to do this, and find the queen; or, like M. Hermann, make the bees pass in review, and I wish any one would inform your readers how he does it: and, consequently, the only other way I know is to fumigate.

18th September (South Durham).—I, yesterday, saw drones going into two of my hives. One I have had at the moors, the other I have had to feed. I could hardly believe my eyes, and having my net in hand caught one, and so saw that it was right. One of my old Ligurian stocks from throwing off two good swarms has left herself weak in bees, and as it is a large hive, 20 inches square, I must add some more bees to it. Would you kindly say if I were to take the queen away from a this year's swarm, and then put the hive and bees on the top, there would be any chance of the Ligurian queen and bees going up into the hive, so that in the cold weather I should be able to take away the bottom hive, as I fancy a small hive swarms sooner than a large one, and I wish to increase my Ligurians? Would you also say if moist brown sugar answers for feeding bees? The poor people round here use it, as they cannot afford to buy the lump at 5½d. and 6d.; but I fancy unless it is good, and a light colour it does not answer well.—A. W.

[It is certain that working bees do not live much above six months. The common bees which you find in your Ligurian stocks and swarms have either strayed from other stocks or have been bred by the Ligurian queens. A little practice is all that is necessary to enable you to drive bees with ease and certainty. When this has been effected the cluster may be readily knocked out upon a cloth, and the bees passed in review as described by M. Hermann. The existence of drones at this season would lead to the suspicion that the hives in which they are found are either queenless or have drone-breeding queens. No time should be lost in ascertaining how far these suspicions are correct. If you place one live upon another after removing the queen of the upper one, the bees (after probably more or less fighting, in which we have known the only remaining queen to be sacrificed) will unite, and ultimately descend into the lower hive, first hatching out any brood there may happen to be in the other. Bees will sometimes do well on syrup formed of brown sugar, but lump sugar is decidedly better, and the difference in price inconsiderable.]

BEEES AT WOLVERHAMPTON IN 1861.

It is interesting to observe the different reports received from various parts of the country, relative to the success of apiaries in different localities.

A correspondent living about seven miles north of London tells me that the season there was uninterruptedly favourable till near the end of August, and that swarms lived quite in the latter end of June (the 25th) weighed upwards of 43 lbs., exclusive of the hive.

Here bees have fared worse than what they did last year, when early swarms (both first and second) which had time to lay in a sufficient stock of provisions to carry them on through June, were enabled to amass a considerable quantity of honey in July.

I weighed an old hive, and a first and second swarm in August 1860, with the following results:—Old hive 25 lbs.; first swarm, 40 lbs.; second swarm, 33 lbs.; exclusive of the hives. But I find on inquiry this season that a great number of swarms have died of starvation since the commencement of August, and I have found it requisite to feed my own bees (no honey has been taken from any of them), comprising two stocks and two swarms (one of the latter a very populous hive of Ligurians which I obtained from Exeter in the beginning of July) very liberally. They have already had 40 lbs. of lump sugar dissolved in 20 lbs. of water and boiled for a few minutes, and are still scarcely up to weight, and I expect the mortality this winter will far exceed that of last.

I administered the syrup in bottle-feeders made according to my own directions, with very short necks and wide mouths like glass ink-stands, containing 4½ lbs. of syrup when filled. The neck is 1½ inch wide inside, and not more than half an inch long, so that when inverted over the circular hole in the top of the hive, there is still plenty of room for the bees to pass freely over the comb-bars underneath, whilst the square shoulder of the feeder resting flat on the crown-board closes the circular aperture against all intruders. If a piece of perforated zinc is put over the bung-hole a short time before applying the feeder, the free admission of cold air will induce the bees to retire from the aperture, and allow the feeder to be inverted over them without risk of annoyance to the operator, or danger of crushing the bees. A puff or two of tobacco smoke will make them retire at once, if the delay involved in the first method is objected to. Tiffany, such as is employed for protecting fruit trees, tied tightly over the mouth of the feeder seems to answer very well, and the same piece may be employed several times; but muslin is generally soon eaten into holes when the feeder has been emptied. The ½ lbs. are generally taken in a little over twenty-four hours.—J. E. B.

DRONE INFLUENCE.

TO WHAT DISTANCE DOES IT EXTEND?

SOME time last year "A RENFREWISH BEE-KEEPER" inquired as to the probable effect of Ligurian drone influence upon neighbouring apiaries. Whilst replying that this influence must at all events prove beneficial, by introducing new and superior blood into any apiary which might be affected by it, I had no idea that it would make itself felt, except in cases where bees were kept by tolerably near neighbours. A circumstance has, however, recently come under my observation which proves that the flight of either queens or drones must extend much farther than is generally imagined, and that drone influence may extend over a greater area than I had previously deemed possible.

About the second week in August I drove a stock of condemned bees, which was fully two miles distant from my own apiary. During the operation I was much surprised at finding a portion of them distinctly marked Ligurians. Although the bees which bore the distinctive mark were in a decided minority (probably not more than one-tenth) as compared with the common inhabitants of the hive, they were sufficiently numerous to negative the idea which first occurred to me—that they might possibly be the remains of a band of foragers from my own apiary which had thrown off their allegiance to their sovereign, and had cast in their fortunes with a native colony. The next hypothesis was that the queen (which was a young one, the stock having thrown two swarms during the summer) might have been impregnated by one of my Ligurian drones, which would, of course, at once explain the whole affair; but looking

at the distance which separated the two apiaries, and having regard to the fact that there were probably some thousands of drones in the four or five colonies which formed the apiary at the time the last swarm issued, of which some hundreds still survived in two adjoining stocks, this hypothesis appeared almost as improbable as the one which had first occurred to me. Being extremely unwilling to leave this mystery unsolved, I took especial care of the queen, and presented her with a few workers to my friend Mr. Fox, who succeeded in placing her at the head of one of his stocks. On the 16th ult., I received a note from him, in which he tells me that Ligurians have made their appearance in the hive to which he had introduced her. This appears to settle the point, and proves beyond question that drone influence may make itself felt at a distance of fully two miles.—A DEVONSHIRE BEE-KEEPER.

AGE OF THE QUEEN BEE.

EVERY apiarian should know, as far as is practicable at least, the age of every queen in his apiary.

Those who depend upon natural swarming may save themselves much trouble, and frequently the loss of a swarm, by knowing the age of their queens; or, from which stock to expect a queen that will not fly, which she seldom fails to do, except when enfeebled by age.

When a swarm issues, if the queen is too old to fly, she drops to the ground, and, if not picked up and put with the swarm, is usually lost, and the swarm returns to the hive, and must wait the same length of time that would be requisite to bring out a second swarm; and sometimes will not come out at all.

If the apiarian does not expect a feeble queen, the swarm will generally return to the old hive before he is aware that she cannot fly. Then his only alternative is, if he finds her, to return her to the hive, and she will generally come out again the next day, if the weather is fair.

The queen will fly until she is four years old. At four she is too much enfeebled, and will generally, perhaps always, fail to fly, though her wings may appear to be whole. There may be instances when a queen will fail to fly from some other cause; but such very seldom occurs in natural swarming. The old queen is sometimes destroyed and a young one substituted. In such a case the queen might fly when she is supposed to be too old to do so. When such an instance occurs, I call her one-year-old, presuming that the old queen has been changed off the preceding year.

I will give my method of knowing the age of the queen.

An old stock that cast a swarm last year, or an after-swarm last year, will have a queen one-year old.

I mark my hives thus: if a first swarm, on the 15th day of June,—

1st. June 15th, 1861—1. If an after-swarm, thus: 2nd, June 15th, 1861.

The first figure 1 denotes a first swarm, then the date, the last figure denotes the age of the queen.

A figure 2 denotes a second swarm, of course a young queen.

The hive from which this swarm came, I mark thus:—

1, June 15th, 1861, in another or different place on the hive, so that I can readily distinguish this from the mark at flying.

By referring to this simple record on my hive, I am not at a loss to know when to expect a queen that will not fly.—C. COE, Union Springs, N.Y.—(*American Bee Journal*.)

[The foregoing suggestions are of value. The age of queens is, without doubt, a very important point in bee-keeping, and should be noted wherever practicable. Independent of this, there is a very great variation in the breeding powers of different queen bees, and every endeavour should therefore be made to furnish stocks with queens of the greatest degree of fecundity. It is in this respect that I have found Ligurian queens excel all others.—A DEVONSHIRE BEE-KEEPER.]

APIARIAN NOTES.

IN answer to your excellent correspondent, "A DEVONSHIRE BEE-KEEPER," I have grave doubts that a virgin queen lays drone eggs. From analogy take the wild bees, or bumble bees as they are vulgarly called. The queen mother of all the genus of Bombi, at least to the number of fifteen species—all social bees, which live in more or less numbers in communities—the queen

mother of the whole of these is impregnated between the middle of July and the end of August, in England, and she remains in a dormant state in the earth after impregnation until the following March or April. She commences nidification generally from the beginning or middle of April to the end of May. In most seasons the first workers appear about twenty-five days after the comb is made, generally only one or two at first. Towards the last week in June, and sometimes a fortnight later, the males appear, and immediately after the young females, which are the founders of the colonies of the following year. These latter are impregnated by the drones, and only one impregnation ever takes place, the effects of which last until the whole of the bees are hatched in the succeeding summer. The workers and males of all these species perish before winter commences.

As the "DEVONSHIRE BEE-KEEPER" is one of the new school, I strongly recommend him to get a bee-book published by the ingenious Mr. Huish about fifty years ago, in which that gentleman throws overboard all the theory of the immortal Huber by a stroke of his pen. Mr. Huish insists that there is no connection between the queen mother and the drone, "that the aura" of the drone fecundates the eggs, but that the queen has the power of laying all the eggs both of drones and workers, and, of course, queens (which in precedence I ought to have mentioned first). He then, I am sorry to say (*de mortuis nil nisi veritas*), enters into a long tirade against poor Mr. Huber for many pages, condemning the whole of his work as an imposition on the gullibility of the public. Mr. Huish's work is a very comprehensive one, and, I think, contains more matter of one sort and another than almost any of the sort extant.

Should a hive lose its queen and no confusion take place in consequence, depend upon it there is another young queen in embryo, or one ready to take her place. This must have been the case in the account given by the "DEVONSHIRE BEE-KEEPER" in a late Number of THE JOURNAL OF HORTICULTURE.

Water ought to be given to bees from the middle of March until the end of the swarming season, as they require water only during the great breeding season. I have found the easiest method is to use a moderate stone trough filled with pebbles to the brim, or pieces of wood floating at the top of the water. The wood should cover nearly the whole surface. I have noticed frequently that fresh rain water is preferred to pure spring water, by the eagerness with which the bees settle on the leaves of plants or trees after rain, even near the usual place—the trough intended for them. Where there are nice, gravelly, shallow, running brooks, there is no occasion to offer water.

One of your correspondents is puzzled at Mr. Taylor's description of a good bee country. There is little obscurity in the statement. What Mr. Taylor means is, I think, quite true—that a rather poor country, such as is found in parts of Dorsetshire and Hampshire, where there is abundance of heath, is better adapted for bees than a highly cultivated country without heath, although the land may be let for double the sum or more. Parts of Hampshire near the New Forest will support many more bees than the richest tracts which can be found. There are heath and white clover in abundance, and numerous wild flowers, trees of all sorts, and honeydew, &c.

The honey of the past summer is of excellent quality; I do not remember to have tasted better.

The finest honey I ever met with was in the north of Devon, and it was at the end of a showery summer—1840.

I hope soon to read a favourable report of the Ligurian bees from some correspondent, and detailed particulars as to the quality and quantity of honey taken from some of the most flourishing stocks. From the appearances and the southerly and westerly winds continuing over the equinox, we may expect a mild winter very unlike the last.—H. W. NEWMAN, *Hillside, Cheltenham.*

VARIETIES.

APPLE DUMPLINGS.—In every paper you will see some time or other the query, How can I make light pot-pie? How can I make light apple dumplings? And certainly I had rather go hungry a little while than eat the slices of "specific gravity." I have before now nattered for politeness sake. Some time since I promised to give our way of making apple dumplings which is as follows:—Having pared and thinly sliced the apple, I rub butter in the flour nearly enough for an ordinary pie-crust; mix a little soda in some water, and pour enough in some butter-

milk to make it foam—any more than this is injurious; now moisten the crust about as soft as ordinary biscuit, roll out and butter it over lightly, then double it over once and repeat. Put in no more apples than the crust will easily lap over on, and two small dumplings are better than one large one, as they are more easily got into a bag, and take less time in cooking. When the fruit is cooked the pastry is done, and the time of cooking must be regulated accordingly. If we cook the fruit before putting it in, half an hour is sufficient to boil an ordinary-sized dumpling made in this way—though in roll-form two hours are necessary. Pudding-bags must be kept sweet and clean, dipped in boiling water and well floured on the inside before using. A good sauce to be eaten with apple dumplings is as follows:—To a pint of boiling water add a good slice of butter, half a nutmeg grated, two table-spoonsful of flour, previously mixed in cold water, and half a tea-spoonful extract of lemon, with a coffee-cup full of white sugar; boil one minute. As far as my experience has gone, heavy apple dumplings are owing to too much cooking, or want of enough shortening, or perhaps a poor fire, and water not boiling to start with.—M. J. STEPHENSON.—(*Practical Farmer.*)

WHITEWASH.—Whitewash is one of the most valuable articles in the world when properly applied. It prevents not only the decay of wood, but endures greatly to the healthiness of all buildings, whether of wood or stone. Outbuildings and fences when not painted should be supplied once or twice every year with a good coat of whitewash, which should be prepared in the following way:—Take a clean, water-tight barrel or other suitable cask, and put into it half a bushel of lime. Slake it by pouring water over it boiling hot, and in sufficient quantity to cover it 5 inches deep, and stir it briskly till thoroughly slaked. When the slaking has been effected, dissolve it in water, and add 2 lbs. of sulphate of zinc, and 1 lb. of common salt. These will cause the wash to harden, and prevent its cracking, which gives an unseemly appearance to the work. If desirable, a beautiful cream colour may be communicated to the above wash by adding 3 lbs. of yellow ochre; or a good pearl or lead colour by the addition of lamp, vine, or ivory black. For fawn colour, add 4 lbs. of amber, Turkish or American (the latter is the cheapest), 1 lb. of Indian red and 1 lb. of common lampblack. For a common stone colour, add 4 lbs. of raw amber and 2 lbs. of lampblack. This wash may be applied with a common whitewash-brush, and will be found much superior both in appearance and durability to common whitewash.—(*Chem. Gazette.*)

BUTTERMILK FOR GAPES IN CHICKENS.—A correspondent says, "Feed chickens with plenty of Indian meal made into a dough with sour buttermilk, and they will not be troubled with the gapes."—(*Genesee Farmer.*)

OUR LETTER BOX.

GET IN A DRAKE'S FOOT (Poultry Fancier).—Wash the cut of the drake's foot thoroughly, and be sure you leave no stone or pebble, not the smallest, in it; if you do it will fester. If there is inflammation poultice it; if there is not, tie it up in leather, and let the bird walk only on the grass. It will soon be well.

COCHIN-CHINA HAN SOT LAYING (Cochin).—No one who wishes for a good supply of eggs keeps a Cochin-China hen after she is one year old. Your hen is three years and a half, and is becoming worthless. You might get the Indian corn from your poultry diet. Barley, oats, and potatoes would be better.

PATENT CATTLE FOOD (A Subscriber).—If you give your cattle the best meal, and the best oil cake, you will fatten quite as fast, and very much cheaper, as you could with any patent food.

YOUNG MULE BIRDS DYING (L. B.).—It is a common occurrence for young birds to die about the moulting time. I think it often arises from feeding them on too heating or exciting food, such as rape, &c. and bread. It is like pampering the appetite of a child on hot and highly-spiced food and brandy, &c. Plain, nutritious, unstimulating diet will produce a strong, healthy constitution, and enable the birds to moult without difficulty.—B. P. E.

FEEDING BEES—MOISTURE IN BEE-HIVES (A. W.).—My bees did quite at well last winter on sugar and water as they could possibly have done on honey. I gave no specific quantity to each hive, but fed until they were heavy or ought to stand the winter. I was certainly much annoyed by the presence of internal moisture, but do not believe the quality of the food had any influence upon this evil. I am quite undecided as to the best plan of getting rid of it, but object to ventilation during winter. At present I avoid lateral windows, and allow only one in each box. I also intend trying unpartitioned boxes not exceeding seven-eighths of an inch thick, and with efficient external protection. I fully agree with you as to the superiority of Ligurian bees.—A DEVONSHIRE BEE-KEEPER.

SILKWOORM'S EGGS (F. W. Torte).—These (the common) may be bought at some of the shops in Covent Garden Market. We do not know where those of the Atlantic silkworm are to be bought. Seeds are best sent to Australia in separate small cypress bags (no paper) each suspended by itself from the ceiling of a cabin.

WEEKLY CALENDAR.

OCTOBER 15—21, 1861.			WEATHER NEAR LONDON IN 1860.

METEOROLOGY OF THE WEEK.—A. Chickwick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 53.7 and 19° respectively. The greatest heat, 76°, occurred on the 11th in 1843; and the lowest cold, 22°, on the 19th in 1843. During the period 130 days were fine, and on 108 rain fell.

VARIATION, CROSS-BREEDING, AND MULING OF PLANTS.

It is only recently that my attention was directed to your magazine for animadversions on an article I had written in a contemporary, on the variation in the leaves of plants; and having now possessed myself of the whole Numbers of your current volume, I have read with interest the very ably written articles of those who have so animadverted on the remarks I made, and also with still higher interest the doctrines of Mr. Beaton on the same subject. However much I lament to stand opposed to so eminent an authority as Mr. Beaton, whose vast experience and great powers of observation entitle his opinions to much respect; yet as he, and he only so far as I can see, maintains the belief and asserts it as doctrine not to be gaisayed that variation is not disease, I do humbly demur to that assertion, and adhere to the views I adopted—that it is.

I cannot appeal like Mr. Beaton to the experience of forty years, but I can do so to at least half that term, during which time I have made no end of experiments which, if one-tenth of them had succeeded, would have gone far to establish the Lamarckian doctrine so recently revived by Mr. Darwin—that all plants now so diversified had their beginnings in a few original forms. How impressed with this belief I laboured to establish it, by trying to unite races and genera very distantly allied. I would now be ashamed to acknowledge in detail. But of this again.

How stands the question, and how stand opinions for variation being health or disease?

The opinions of an "OLD SHOWMAN," which I generally endorsed by my own views, have been animadverted on as I have observed, not controverted by the other writers who give evidence, or offer remarks on the question.

"NICKERBOR" (why should men who write so well as "NICKERBOR," an "OLD SHOWMAN," or "G.," not give their names in full?) no doubt sets out holding with deference "that variation is not disease;" and he cites the case of "the variegated Pelargonium Flower of the Day" not being a seedling, as an "OLD SHOWMAN" believed, but a sport, or if he will have it so, a diseased branch of a Scarlet Geranium whose history was known, and from which he, "NICKERBOR," once raised a batch of seedlings, every one of which "was variegated or diseased from the seed-lobes." This I can perfectly well understand. It is the common case of a diseased parent transmitting its taint to the progeny, of which we have instances every day as well in the animal as in the vegetable world. He next notices my own experiment of seedlings raised between the white-flowered and the

scarlet-flowered Geraniums as adverse to my own views, and as tending to show that variegation is not disease. But may not disease be in the root as well as in the branch, in the seed as well as in the leaf? That is what I contend for, and I do think my experiment repeated, be it remembered, and with like results both times, proves it, and Mr. Beaton to this extent confirms the fact, that the disease or affection, for he disputes disease, is in the pollen. My white-flowered Pelargonium was the first of all its race I ever saw or heard of. It was given to me as a white-flowered variety of the common Scarlet Geranium, and I believed it to have been accidentally raised from seed, just as the Venus viciatrix, or first white-flowered Fuchsia was obtained; no one could tell how. But I do not know, and cannot vouch for its origin. If it was in itself, by whatever law, a departure from its kindred in the flower, might not a like departure be transmitted to the foliage of its progeny? Be this as it may, it certainly originated in the pollen—i.e., in the male, and not in the female parent; for when the cross was inverted, and the white-flowered kind made the seed-bearer, the healthy pollen of Tom Thumb was attested in the unbroken verdure of the seedlings, no malaffection ensuing from the taint or disease (supposing it present) in the seed-bearer. This is a fact, if it be not a law, worthy of being recorded, and I rejoice to be at one with Mr. Beaton upon it. But to proceed.

In this experiment "NICKERBOR" can maintain nothing against disease being the cause of variegation. I agree with him the result is remarkable.

I am not to dispute the indelible nature of variegation in some plants, though it is far from permanent in all, and I know of none where it is more fixed than in the Arundo donax, var. versicolor, or common Gardener's Graters, a plant whose variegation, I believe, no cultivation will eradicate. But it will be observed that this is set down by London, I presume correctly, as a sport of 3 feet in height of the true Arundo donax, which he sets down as 10 feet high. Now, if this do not instruct disease in the striped variety, it establishes a great shortcoming in the vigour which accompanies the non-variegated original species.

This brings me to notice the very candid, and I think just comments offered by your other correspondent "G.," who, though following suit to "NICKERBOR," frankly admits "one thing which may go far to support Mr. Anderson's views, and that is—that variegation is, I believe, invariably accompanied with a considerable diminution in vigour of growth." I do hold with "G." that this fact is invariable. Let any one look at a variegated plant, and compare it with its non-variegated congener, or with the leaves of a stray shoot (which may often be found on a variegated plant) having leaves of unvariegated green, and compare their separate aspects, he will find the green tree or shoot possessed of a vigour and full development of leaf which are not in the variegated one. On going round our Botanic Garden here lately, with Mr. McNab, the curator, I observed a striking instance of this in a variegated Oak, a tree of some 10 feet or

12 feet high, and well spread on the top, no great dimensions for an Oak certainly, the leaves of which were all less or more attenuated, and as if nipped round the edges, the true outline being deficient in all of them. But amid the variegation, there arose a shoot or two of deep verdure, and here the leaves were entire, and about twice the size of the variegated ones. The case is common over all or most variegated plants, inasmuch so, that but for the high authority arrayed against my views, or the views which I endorsed, I would have left the question to its fate, or its own solution.

But I must cite the testimony of no less a witness than Mr. Beaton himself to support my views. He tells us (page 312) what Mr. Standish has done, and can do among Rhododendrons in this way, that he can cross these, great and small, "down or up to the verge of variegation, and until there is not a particle of colour in the leaves, and no art of man can grow the seedlings; yet every one of them is in perfect health, according to its own degree of existence." Now this is just what I contend for. If Mr. Standish cannot get these blanched shoots to grow, it is just what I learned from his own lips not long since when he visited me here, and what my own experience taught me more than ten years ago, when I got some shoots entirely blanched among the variegated batch of crossed seedling Pelargoniums referred to, which, as they made no progress on the plant, I tried, but tried in vain, to strike as cuttings. Truly this looks very like disease. It is a pure albino, whose unhappy state in the human family, few, I presume, regard as anything but as diseased.

But I will not fall out with Mr. Beaton, "NICKEBOB," or "G." about names. We are all at one as to the main thing—that if it is not disease it is an affection of the plant entailing impaired vigour, and, I hold, diminished growth, whose true cause, whether originating in the seed or occurring in the branch, it is alike desirable to have ascertained; for there is at present a rage for these variegated things, and if the laws which produce or affect them can be clearly shown, then it will be profitable to some and instructive to all to know them.

I had gone on thus far when your new Part for August reached me, and there I found a much higher and more reliable evidence given to the same effect with my own in the excellent article by Dr. Morren, whose very searching investigations must settle the question thus far—that variegation is disease; for, after going over M. Sageret's conclusions, some of which may be exceptional, he sums up by observing, "After this exposition of facts variegation may be regarded as a malady." The various causes assigned by M. Sageret—such as the seed being too old, imperfectly ripe, or defective in conformation, or that impregnation was imperfect by immature pollen, &c.—all necessarily infer that variegation is the result of disease, or imperfection of some sort in the seed, where it originates in the seedling. This very scientific paper must be held to close all further debate; yet the causes which produce such results are still a mystery, whose solution the practical physiologist has still to make out, the way to which certainly has been made less difficult by the facts and experiments communicated in the papers referred to.

I had intended, ere I concluded this paper, to have gone a little into the subject of all-engrossing interest of hybridising and cross-breeding of plants, upon which Mr. Beaton in his recent papers has thrown much light and communicated many facts known to few if any before. But though I cannot now go into the subject, I may take it up at a future time, and state some results of my own manifold experiences in this way: by many of which I will corroborate Mr. Beaton, though, on the whole, what I have made out warrant me in expecting much stranger things to be accomplished "than have been dreamt of in his philosophy." Few take into account the possibility of doing at one time what they have failed to do at another, and so abound in disgust experiments which may have oft before led only to disappointment. The patient experimentalist must wait weeks and months for a favourable time. In my article in Mr. McIntosh's "Book of the Garden,"* I insisted upon this being studiously watched for and improved. All my subsequent experience confirms me more and more in that view. Few such days as I considered fit for hybridising (not merely crossing), occurred in this bygone summer, and scarcely any in the summer of last year. Many things all but given up as hopeless I would

resume on an auspicious day (which in this climate are truly like angels' visits)—a day not of strong but of subdued sunlight, with a sky so charged with electricity as to give a buoyancy to the spirits and elasticity to the limbs—a day when man, and bird, and beast are in their most joyous mood—seize such a day and shun "the short anthers;" and Darwin himself might yet take heart of grace and do something to sustain his own doctrines. These doctrines I long clung to, and gave up only after hundreds of failures. But I gave expression to one view in the paper above referred to—in the "Book of the Garden," vol. ii., page 320, which I think has not been fully if at all regarded by Mr. Darwin or any other naturalist bearing closely on the subject of these inquiries—namely, the gaps, some greater and some smaller, which occur between various orders of plants. May there not have been, ere this globe suffered from so many disruptions, an affinity between plant and plant, which, by the losses these convulsions occasioned, is now also broken up and so creating these gulfs between which have given rise to races, genera, and species of all the various dissimilar forms we see around us? May there not, too, have been, in the early stages of this world's history, a very different state of atmospheric properties from what now obtains more favourable to the ends in question?†

Having already trespassed on your space so far, I must now draw to a close. Ere I do so, however, I must congratulate and compliment Mr. Beaton on his discovery about the "short anthers." At page 312 of your last volume he observes, "In the great bulb of Scarlet and Horseshoe Geraniums there are but seven stamens, four long ones, one of medium length, but which is often wanting, and two almost sessile like the anthers of Wheat—that is, very short indeed, and opening at the bottom face to face. These two are they which reduce a whole family to beggary—first to dwarfs or Tom Thumbs, or, better still, to Minims," &c. I cannot express how much I was taken by surprise by this remarkable enunciation; for I had from time to time, for ten years past or more, been drawn to consider the purposes of these short stamens in the races of the Rhododendron, and wrought with them till I produced the very results Mr. Beaton has observed.

The Rhododendron Edgeworthi had no sooner delighted cultivators with its lovely, large, sweet-scented flowers, than the desire became general to transfer its rare properties into a dwarf progeny. And many, unhappily, for this purpose began their operations by attempting crosses on this species. The results were a disappointment; for where seeds were produced the progeny were found, I believe in some cases only after many years, to be pure Edgeworthi, native pollen having, perhaps, by means of insects superseded the foreign application. I fortunately started on the proper track, and made the crosses with its pollen on the other species. But it may be proper and interesting in passing here to mention, that though I have often subsequently tried to make the cross upon Edgeworthi, I never

* I took this view in the article referred to ("Book of the Garden," vol. ii., page 319). Nature, as conjectured by Linnæus, was occupied by but a few and simple types of the generally vegetable forms which have been transmitted to us. How these few first types, if that great authority was right in that belief, have become varied and multiplied from classes to tribes, from tribes to genera, and from genera to species and endless varieties, belongs to those mysteries of Divine agency which set all inquiry at naught, and upon which it were equally unprofitable and presumptuous at the present time to speculate. For who, entreating of such a science, dare invade a field where the Omnipotent evoked no aid from man, ere yet, indeed, man was—while the sun, and skies influence, and the whole host of insect races now extinct, were perhaps but parts of the agencies and instrumentalities by which

"With herbs, and plants, and fruitful trees,
The new-formed globe He crowned,"

and made it fit for man's use and habitation? Who can speculate now on these, or those atmospheric properties, which, in contact with life, under whose influence man grew and increased in strength till the span of man's existence extended to near a thousand years—when there were giants on the earth—

"When man was in stature as towers in our time,
The firstborn of Nature, and, like her, sublime,"

—a life-giving and a life-sustaining Spirit breather the will and effected the purposes of the Creator? Perchance a larger portion and a more genial form of electricity than now obtains may have imparted a principle of higher vitality to the air, and through that medium have communicated a stronger impulse and more enduring energies to both animal and vegetable life. This may or may not have been; certain it is that a change has taken place. Since the Deluge the vital forces have been greatly weakened. Man since then has scarce lived a tithe of his former term; and the vast extirpation of fossil flora bespeak an exuberance and variety of vegetation in temperate zones that have no parallel at the present day even in tropical regions.

* This paper will be found in the "Book of the Garden," pp. 319, 320, 321, 322; and the practical portion of it has been honoured with a place in Professor Lindley's last edition of the "Theory of Horticulture," pp. 490-494.

succeeded in getting seeds from any cross so attempted upon that most untractable species.

I began my operations on another pure species of Dr. Hooker's introduction—viz., *R. ciliatum*, both being from the Sikkim ranges of the Himalaya, the latter having all the fine dwarf habit, the absence of which is the great fault of Edgworthi, a straggling, ungainly thing. Well, to work I went, and as my great aim was to make the progeny as puny as possible, I purposely used the two short anthers which Mr. Beaton refers to. But I used long as well as short stamens. These crosses, which were effected in the spring of 1855, took, and I sowed the seeds in September and October of that year. There were five separate batches, marked A, B, C, &c. Now, of the taller-growing kinds, I have two plants set with flower-buds. But these were a set of dwarfs, which, with all my care never raised their heads above the pots, and these, so far as they are now living, creep along with small tufts of foliage on the surface of the pots, pretty enough in their way, but without showing the least appearance of bud or blossom. Through the six years of their existence the tallest have got shifted; but I have no doubt they are the pigmy progeny of the short stamens.

Mr. Beaton as the first, perhaps, to find out, and certainly the first so far as I know, to announce this strange discovery, is entitled to its full merit. Its full value has not yet been sufficiently tested. For although I have produced the tiny things in the Rhododendron family which he has done with *Pelargonium*, inquiry should not stop here. And for my part I did not limit my aim merely to produce by them more dwarfish plants than the parents. Regarding as I did, the pollen of these small anthers as of finer particles than the pollen of the longer and larger ones, I used it as a provision of Nature's own suggesting, in preference to the latter in crossing the smaller species whose pollen-tubes I feared might not admit the grosser globules of these larger anthers. And when the two dwarf stamens failed, I still cling to the belief that in this way I effected crosses in which with larger anthers I should have failed. I look on them as affording the chance of effecting unions with remote species or genera—as the links, in short, by which large and family groups might be united. These were in the days of my Lamarckian notions; and the recoil consequent on the failure of the fanciful theories I then indulged, discouraged me from pursuing or even recording the results of my experiments with them. I did wrong in this, and fresh trials ought yet to be made; and though these odd pair of tiny stamens are peculiar, perhaps, to the *Pelargonium* and *Rhododendron*, yet stamens analogous whose pollen possesses like properties, may be found in other races. The experimenter should go bit by bit, and never despise the day of small things, and if he cannot produce a mule between a Raspberry and a Strawberry, or a Currant and a Gooseberry (I never tried the latter), let him try the muling of more nearly allied things. I do not despair yet of producing a mule between the Blackberry and Raspberry. I made the effort this past summer, but my experiment was marred by an accident. I certainly did try for a mule between the *Rubus idaeus* and the Strawberry, and the latter with *Rubus glabratus*, an Andean species which I alone possess, from both of which crosses I have young plants, the Strawberry being the seed-bearer in both. Though the seedlings are dissimilar to look at, I cannot touch as yet for the crosses being true. I have a plant of the former cross, now three years old, which has never yet fruited. The leaves often divide into four instead of three lobes, and the footstalks are much more wiry or shrubby than the Strawberry. Here Myatt's Pine was the seed-bearer. There seems evidently a variation from the female parent, and though, certainly, it is most like the Strawberry, there is little disposition to throw off runners. My other crosses in these tribes being of this summer, the seedlings are too young to hazard any opinion about them.

These trials may suggest similar experiments to others. This is not a field where any one can assign a definite limit beyond which, in some favourable season, another may not go, and none should be discouraged by another's failure. Neither should the bold experimentalist follow suit to the most enlightened. As the most valuable discoveries in medicine have been made by those whom the faculty call quacks, so may like success await those who here adventure somewhat on their own inventions. Yet let them not go to far extremes, else failure and vexation will inevitably be the fruit of their labours.—ISAAC ANDERSON HENRY, *Hay Lodge, Trinity, Edinburgh.*

ANNE BOLEYN AND OTHER HIGHLY PERFUMED PINKS.

As recently as 1840, which seems but as yesterday, the best of all the spicy-scented flowers, the most wholesome of all the scents of flowers that one could get for love or money for Christmas-ree, was one sort of *Dianthus*, a cross-bred Pink between a common rose Pink and a deeper-coloured single seedling of a Carnation, and that sort was called Anne Boleyn. If any one would give me now a pair of plants of that Anne Boleyn I should feel very much obliged. The reason I want it is this: it was the very best cross that ever was raised between a garden Pink and a half-wild Carnation, as ninety-nine seedlings out of every hundred of all the Carnation seedlings I ever saw might be called. I want to cross with it again among the new races of English, Chinese, and Japanese *Dianthus*es, unless some one with more leisure should volunteer to do the thing for me.

We English florists are certainly the most extravagant class of men under the sun. We spend no end of time and money to get new plants from the ends of the earth. We increase and multiply them with an astonishing rapidity, and we cross as many of them as will submit to the process; and the moment we get hold of a seedling out of a hundred which is inclined to some strain or other, which some one or other of us has a fancy for, away go the ninety-nine to the rubbish-heap, and the pet seedling has more indulgence than would suffice to prove that ten or twenty of the seedlings which were cast out in the hurry had better properties in bud, so to speak, than the one which was made choice of, because its properties were one or two years sooner out of bud, and fit to be seen.

It is not money or skill we want at all—in deed, we have too much of both for our good; what we want is patience and industry in the prosecution of races of garden plants for improvement. There is not one class of plants that we prosecute for improvement, of which we might not have had double the number of sections, or strains, or class, or whatever we may call them, and of some of them from six to a dozen sections, and the plants in each of these sections might just be as good as those we now possess or have possessed in a single strain. These multiplied sources of enjoyment have been lost to us for our want of patience, and through a vitiated taste, which expelled every seedling of the ninety and nine because they did not seem to us to be so quick in showing of what properties and proportions they were made of.

Dianthus is one of the happy families to which we lend a helping hand; but like all the rest of the families which enjoy our support and patronage, ninety-nine out of every hundred of the seedlings are sent to destruction for not being what we, or some of us, pride ourselves in rearing.

Now, be it known to all whom it may concern, that of all the properties of which flowers can be possessed, the best property that any of the race of *Dianthus* can ever be gifted for my own eye and for my nose, is to be of the most grateful, spicy, or aromatic fragrance; and the next property to that is a most pleasing colour; and the third and only other point I would insist on, or be thankful to obtain, would be a habit of perpetual blooming, or what you might call an evergreen clumping Moss Rose with yellow flowers. Be it known, also, to all those who do not happen to know it already, that Anne Boleyn Pink is the most true sweet of all the garden Pink races, that its fragrance is a compound of that of the Clove Carnation and the wild mountain Pink, called plumosus, which wild Pink has the most genuine Pink scent of all the family, as the Clove is certainly and better known to be the most gratefully sweet of all the Carnation tribe. And, moreover, Anne Boleyn is the strongest constitution of all the seedlings we yet know of as crosses between some Pigk and some Carnation, and yet retaining the full character and looks of a garden Pink at the same time: therefore, if Anne Boleyn produces pollen, or if it will take to the pollen of others, it would not be going back a step of twenty years to bring it up now for cross-breeding, but the very reverse.

Scent is fast falling out of *Dianthus*, or out of the Clove-works, through injudicious crossing—I mean injudicious in the sense of scenting a flower. The Rose is in peril of the same overwhelming misfortune. A Rose without a thorn and without scent might do very well for a fashionable flower-gardener, but it would not do for a Rose to a lady or to a laundress. Just so with a Pink or Carnation, or anything that might come from the union of the two, and that is my sole reason for wishing a cross bout

with Anne Boleyn. But some long-headed fellow on the continent has been two or three years before me in the race—I do not mean the race of *Dianthus*, but the run to get the cream off the top of *Dianthus*, before it is mixed tops and bottoms.

The Pink called *Dianthus hybridus multiflorus* in the "Illustrated Bouquet," and which was exhibited for the first time before the Floral Committee this time last year by the Wellington Road Nursery, is undoubtedly a cross between the Anne Boleyn Pink and some pale variety of the perpetual tree Carnations. The paleness of the tree Carnation has taken the deep pink out of the Anne Boleyn side of the cross, and my new multiflorous is of a rose pink hue. But I shall get in my best plant of it from the window-sill and examine it again; and so I did, and find I have been mistaken in referring one side of the cross to Anne Boleyn. The other parent must have been much less sweet than Anne Boleyn, or else the fragrance of the particular kind of hybrid perpetual Carnation. The other side of the cross happens to be of very weak scent, as some seedlings do turn out often. At all events here is a key to the greatest want, and the most difficult want to supply twenty years back when I first undertook to have Miss Roses and Anne Boleyn Pinks in the drawing-room at Christmas, as I certainly did the next year after I went to Shrubland Park—that is, in 1841, and what a tremendous hard winter it was. How wonderful has been the progress we have made in gardening since that day; but none of the wonders are more wonderful than that the same parties can now have all but true Anne Boleyn Pinks at Christmas, without the least forcing at all. *Dianthus hybridus multiflorus* can be had by the score, or by the gross, or thousand, to come naturally into first bloom from the end of September to the middle of November, in mild autumns in the open ground, and they can be lifted, potted, staked, and put by for a week or ten days in a shaded place, and after that have the pots on the outside of the window-sill, just as I have them now, or inside where you please, or out in the conservatory—I mean out of pots along the front borders. Nothing can be more sweet than the old Cloves, if we could have them so. But when we come to cross for sweetness we shall use the pollen of all the Cloves, and of all the Pinks and common border Carnations, with the perpetual tree Carnations; and before the end of all our Sweet Williams may be as fragrant as the name is.

Let us go at the object, however, like people of common sense and patience. The result itself, you must keep in mind, is to be the sweetest we can make of all our Cloves and Pinks, to supply rooms and glasses the whole winter through with cut flowers of that stamp, with symmetrical plants of them in bloom from the size of a No. 60-pot, to a pot of No. 16, as full as it will hold of no end of flowering-stems rising from quite a tossack of leaves, Clove fashion. Then by having so many different sizes of plants, as the difference is in pots from 60's to 16's, there will be no bother about being not able to fit the pots with what they have in the rooms to put the pots in. Some have one thing, some another, some are almost too small to hold a 60-pot, and some are not small enough. Then the way to effect the object is, to order as many packets of seeds of all the Clove and Carnation tribes as one can afford; from among the seedlings choose the colours you like best. They will be all but single flowers, but singles are the best for this kind of work. We want all colours for all tastes, and to be able to get them we must use every one of the crosses which we have already, including those from the Indian Pinks, as well as all that have been got from our own garden plants. Some of these have pollen and some have no pollen; some will seed by cross pollen, and some will not seed by any pollen; but which is which, and which will do, no mortal can tell just yet, the fact has to be proved in every way you take it. All we know is, that the garden races of Pinks, Picotees, Carnations, &c., will cross with Indian and Japan *Dianthus*, and with our own Sweet Williams. The aim being to keep the old aromatic scent of the Pink and Clove in the seedlings, and to get as many of them as we can on the model of the hybrid perpetuals in other classes, and in this class of plants also, as is instanced in *Dianthus hybridus multiflorus*, which is a true hybrid perpetual between a Pink and a perpetual-flowering Carnation.

Seeing the ice is broken in that plain case, do you not see the water already clear as crystal to the very bottom of the stream, and all kinds of fishes sporting between you and the bottom? Each one of them, take my word for it, might be made the parent of a new race; therefore, in the name of all that is sweet in the Clove and Pink, do not let the biggest of them absorb all your attention, but let each as it is caught up in your cross-line

have as much of your care and patience as if it of itself would be the father or mother of many natures; and, with all you do, lose not sight of the sweetness of the family.

It has not yet been clearly proved when sweet-scented plants like these are raised by cross-breeding if the scent follows the pollen more than the pistil in the seedlings. We must, therefore, cross both ways, but in every instance let one of the perpetual tree Carnations be one of the parents.

To obtain very healthy free-growing plants, the very sweetest of the single half-wild-looking seedlings of the Carnation seed-packets should be made choice of for mothers; and as frills and fringes are just as likely to be sweet-scented and retain it as quakers' collars, take no thought of how the old florists banded together for obtaining "rose edges" to their seedlings of these races. Your aim and theirs ought to be as wide apart as the poles. They look to the eye, and we must look to the nose and nosegay. They exhibit in summer tints on the edge of a wilderness; but we will present our sweet offerings in the first floor drawing-rooms on Christmas-eve. So there is little danger in our coming in contact or in opposition with better people than our own.

Talk about forcing Pinks after that, and I could tell you at this moment how many kinds of Pinks have been forced during this century, and how many of these I had forced myself between the Paddington Pink and the mountain Pink, and on to deltoides Pink, and the Pink plumosus, for all the old gardeners had years and years at that sort of uphill work; but the next generation will have Pinks, Cloves, and Carnations which will come to bloom when you want them, be it in summer or winter, and that without more forcing than to lift them from the borders and put them in pots. Capt. T. Clarke's mule Pinks, single and double, are the only two kinds I ever attempted to cross. I never saw finer kinds or plants better to grow. The single kind seemed to have some few good anthers full of light blue pollen; but I could no more hit a cross or get a seedling from any of them than if it was with the pollen of the Oak, yet I had a thousand blooms open many days during the six or seven weeks they were in bloom. D. BEATON.

FLORA OF THE ROMAN CLASSICS;

OR, CATALOGUE OF PLANTS MENTIONED BY LATIN AUTHORS, WITH AN ATTEMPT TO IDENTIFY THEM.

(Continued from page 2.)

ACANTHUS.

THERE were two very different plants known to the Romans by this name. One was herbaceous, and, contrary to the received opinion, we believe that this was scarcely, if at all, mentioned by the poets.

The only passage in Virgil that can be applied to it is this:—

*Errantes Hederas passim cum Bacare tellus,
Mistaque ridenti Colocasia fundet Acantho.*

(The earth everywhere yields the vagrant Ivies, together with Bacca, and Colocasia mingled with the shining Acanthus).—*Ecolog.*, iv., 19-20.

Whether these lines apply to the herbaceous *Acanthus* or not, we have very little doubt that it is synonymous with the *Acanthus mollis* of modern botanists, and which was used in medicine by old pharmacists under the name of *Branca ursina*, or Bear's Breech. This is a native of Italy and Spain, and is thus described by Parkinson in his "Paradisus":—

"The leaves of this kind of smooth Thistle (as it is accounted) are almost as large as the leaves of the Artichoke, but not so sharp-pointed, very deeply cut in and gashed on both edges, of a sad green and shining colour on the upper side, and of a yellowish-green underneath, with a great thick rib in the middle, which spread themselves about the root, taking up a great deal of ground. After this plant hath stood long in one place, and well defended from the injury of the cold, it sendeth forth from among the leaves one or more great and strong stalks, three or four foot high, without any branch at all, bearing from the middle to the top many flowers one above another, spike-fashion round about the stalk, with smaller but not divided green leaves at every flower, which is white, and fashioned somewhat like unto a gaping mouth; after which come broad, flat, thick, round, brownish-yellow seeds (as I have well observed by them) have been sent me out of Spain, and which have sprung up, and do grow with me; for in our country I could never

observe any seeds to have grown ripe) the roots are composed of many great and thick long strings, which spread farre in and under the ground, somewhat darkish on the outside, and whitish within, full of a clammy moisture (whereby it sheweth to have much life) and doe endure our winters, if they be not too much exposed to the sharpe violence thereof, which then it will not endure, as I have often found by experience."

How closely this description agrees with one *Acanthus* of the classics we may easily appreciate by comparing it with the following extract from Dioscorides. The herb *Acanthus*, he says, has leaves much longer and broader than those of the Lettuce, divided, dark-coloured, thick, and smooth. The stem is 2 cubits high, of a finger's thickness, smooth, encompassed near the top at certain distances with long, prickly leaves, out of which come white flowers. The seed is yellow and broad. The roots are long, gummy, red, and glutinous.

Pliny the elder (*Nat. Hist.*, l. xxii., c. 22) in describing this *Acanthus*, says—"Acanthus est topiaria et urbana herba, clato longoque folio; cerpidines marginum, adargentumque pulvinorum toros vestiens. Duo genera sunt, aculeatum et crispum, quod brevis: alterum leve, quod aliqui pederota vocant, alii melampyllum." (*Acanthus* is a city and topiary (formable into figures) plant, with an outspread, long leaf, used for clothing the margins of water, and growing against banks. There are two kinds; the thorny and crisped, which is the shorter; the other smooth, which is so called pæderos, and by others melampyllum [dark-leaved].)

Columnella (*De Re Rustica*, l. x., 241) confirms the opinion that this *Acanthus* of the Romans was our *Acanthus mollis* by saying, when describing the Artichoke, "Pallida, nonnunquam, tortos imitatur *Acanthos*." (Sometimes, being pale, it resembles the crisped *Acanthus*) for the entire plant of *Acanthus mollis* very much resembles the Artichoke.

The leaves of this *Acanthus* were adopted as a model by artists in ornamental work. They are peculiarly suited to this by their form, and bold varied outlines; and Vitruvius thus relates how they were first selected to adorn the capital of what is now called the Corinthian pillar. A basket closed by a tile was left with its bottom upon the soil, beneath which was a root of *Acanthus*. In the spring the stems and leaves of this plant grew up around the basket, and were bent back by the projecting tile. Callimachus, a famous architect, saw the elegance of the form and combination thus accidentally produced, and in designing some pillars destined for Corinth, he adopted for their capitals this *Acanthus*-embraced basket.

The other, or tree *Acanthus*, known to the Romans was much more frequently mentioned by their poets and other writers. Virgil speaks of it in the five passages following:—

"Alcimedon duo pecula fecit,
Et molli circum est ansas amplexus *Acantho*."

(Alcimedon made two vases and entwined their handles with the plant *Acanthus*).—*Virgil's Ecl.*, iii., 44-5.

"aut flexi tacuissent vimen *Acanthi*."

(Nor had I been silent concerning the rods of the plant *Acanthus*).—*Ibid.*, *Georg.*, iv., 123.

"Et cum tristis hyems etiam nunc frigore saxa
Rumpet,
Ille coman molis jam tum tondebat *Acanthi*."

(Even when cheerless winter rent with its frost the rocks, he was clipping the leafy twigs of the plant *Acanthus*).—*Ib.*, *Georg.*, iv., 135-7.

"et pictum croceo velamen *Acantho*."

(And a veil embroidered with yellow *Acanthus*).—*Ib.*, *Æneid*, i., 715 and 653.

"Quid tibi odorato referam sudantia ligno,
Balsamaque, et buccas semper frondentis *Acanthi*?"

(Why should I describe to you the balsams exuding from the fragrant wood, and the berries or fruit of the evergreen *Acanthus*?)—*Georg.*, ii., 117-19.

This "evergreen *Acanthus*" was a tree, for Virgil begins this portion of his subject by saying, "Divisæ arboribus patriæ" (countries are distinguished by their trees), and then, after particularising the Ebony of India, and the Frankincense tree of Sabea, he adds the two lines we have quoted.

That this *Acanthus* was valued by the Romans for its pliability is evident from the employment of the epithet "*mollis*;" for though this is Englished by the word soft, it is equally so by the word bending. Pliny the younger ("Epistles," l. v., Ep., 6) in describing his garden, says—"Acanthus in plano

mollis, et, pene diximus, liquidus." (Upon a level surface, is a plant, and, I had almost said, a liquid *Acanthus*). It was evidently a single tree, for there was a walk around it, "ambit hunc ambulatio." In a following passage, after mentioning some Plane trees, he adds, "Post has *Acanthus* hinc inde lubricus et flexuosus." (After these an *Acanthus* waving and bending here and there).

Now, what tree not indigenous to Italy, yet known to the Romans, is evergreen, with waving pliant branches, has yellow flowers, exudes a balsam or gum, has fragrant wood, and berries highly esteemed?

Theophrastus gives us some further indications, for he says that this tree-*Acanthus* was so called because, with the exception of the trunk, it was covered with prickles; even the shoots and leaves were so. The tree was large, yielding timber 12 cubits long. The fruit grew in pods, after the manner of pulse, and was used by the Egyptians instead of galls in dressing leather. The flowers were used in garlands; a gum flowed from its trunk, and a large wood of it was near Thebais.

The *Acacia arabica* agrees with this description most remarkably. It attains the height of 40 feet in Egypt and Arabia, its native country; it is very spiny; its branches are long and pliant; its pods are neck-lace-shaped, like a row of berries; the wood is tough and durable; the skin of the pods as well as the bark of the tree is used in drying and tanning; the flowers are yellow, so as to be suited for garlands and copying in embroidery; and Hasselquist says not only is gum arabic but a frankincense obtained from it.—G.

TREATMENT OF OLD AGERATUM MEXICANUM —LILY OF THE NILE.

In reply to a query in a late Number of your paper you said that "old *Ageratum* keep well in a greenhouse during winter." Am I to understand by this that *Ageratum* grown from seed sown in the spring of 1861, if kept during the winter from frost, will answer for bedding plants in the summer of 1862? and if so, Why are *Ageratum* called "half-hardy annuals" in seed catalogues?

What is the best culture for the Lily of the Nile? Should it be kept in a pan filled with water?—B., *A Subscriber*.

[The answers to correspondents do not always apply to more than the persons answered. There is something peculiar in the case which is told to us in the letter, and we answer according to "something peculiar." Old *Ageratum*—that is, the plain and variegated kinds of *Ageratum mexicanum*, are the easiest of all plants to keep over the winter, and the most easy to make cuttings of early or any time in the spring. *Ageratum* raised from seeds in 1860 will do very well to plant out as bedders for the next threescore years and ten, if they are taken up before they are frosted, and are made into cuttings next spring. After that keep the very same plants from cuttings in the autumn, and do away with the rest of the plants, or keep the old plants and make cuttings of them in the spring. But, of course, the green-leaved *Ageratum* may be sown every year, and then it would be equivalent to an annual, and would need the treatment of half-hardy annuals just as the catalogues say.]

If you have the Lily of the Nile the sooner you get rid of it the more to your comfort. In the first place, it wants a house as hot as that of the Victoria regia at Kew, and in the next place, it would need one of the best gardeners at Kew to look after it, and after all he might look foolish at last for not being able to bloom it. It is the *Nelumbium speciosum*, or Sacred Lily of the Nile.]

SKELTONISING LEAVES.

I HAVE read with pleasure in THE JOURNAL OF HORTICULTURE for September 24th, page 503, an excellent article on the pretty art of skeltonising leaves, &c., taken from the *Friend's Intelligencer*. I approve of it all according to the plan of maceration; but sometimes if the leaves are too long in water the fibre will rot. The only thing I disapprove of in the article is that it takes two or three months for most leaves, and that it would require eight to twelve months' maceration for the Oak, as I assure you, by a plan of mine I can skeltonise any leaf in ten minutes—the Oak being the easiest. I once had a prize and

certificate of merit for fifty varieties of British fruit and forest tree leaves.

Any one wishing to know the secret may have it—I refer them to my advertisement in the present Number.—E. PERSAC, *St. Mary Clist, near Exeter.*

A WEDDING BOUQUET.

In the papers that recently appeared in this Journal on arranging flowers there was a striking omission, and one the more inexcusable, because, in point of fact, the writer had seen and dissected some very first-rate specimens of a wedding bouquet.

This postscript comes, then, to supply that grave neglect, and I hope no lady reader will be wicked enough to call it the most important part of these little hints.

As a general rule in a bride's bouquet, as well as in the general arrangement of wedding flowers, white is certainly the colour to predominate.

It is, however, far more difficult to arrange white flowers well than to do those which give the help of colour, and some of the difficulties are even difficult to describe; though, as I have myself made up a great many of these white designs, I will do my best to describe the principal things that are essential in them. While, as to the mechanical part of the work, I must refer my readers to a former chapter.

Every one knows that there are shades of white, we may call them three—the yellow, blue, and pink tinge; and there is, also, the perfectly snow white, which is of all the loveliest.

The grand thing is to get plenty of this snow white, and then to add whichever one of the other colours may be preferred. The pink tinge, if not more than that of a blush rose, is much the most effective; but it must not be allowed to be deeper than the rosy tint of a pale pink shell.

I do not think any other colour is really good for bridal flowers. Other colours require a more fancied shade; and even the beautiful blue quite alone with white would look rather poor. The only way I think, at least, in which it comes in well, is as a fringe of blue encroaching here and there on the perfect white, and running all round it in little sprays of blue. I once saw a very pretty white bouquet thus edged round with blue. I am not certain now what the flowers were, but they had exactly the effect of pale *Nemophilas*, or *Forget-me-not*; and I think the latter would be, at least, *ben trovato*. These blue flowers peeped out like little stars amidst a shower of the lightest Ferns.

The mention of the Ferns brings to mind one of the greatest objects in introducing colour. Unless this is done the green itself is hard to keep sufficiently in the background. My readers will see at once that an ordinary bouquet deprived of its gayer flowers would be at once green and white, and this we have to guard against. At the same time, to have green is essential—no bouquet can do without it; and, I think, the way of best avoiding this serious objection is to have flowers to which green belongs so naturally that they can scarcely be deprived of it. White Clematis, Snowdrops, Banksian Roses, Flowering Myrtle, strike me at once to mention as amongst this number, and even here I prefer naming the common flowers—unsurpassable, indeed, in loveliness, but such as all must know. All flowers almost, however, have some green of their own, which cannot be unconnected mentally from the flowers when they are seen together.

The white Rose, for instance, with the spray peeping up beside it; the white Camellia, with its large shiny leaf; the Lily of the Valley with its snowy bells lying in their cool sheath, if we want green—and we must have green—it must be brought in thus.

Perhaps this is one reason why it is often well to make up such bouquets piece by piece on the smallest and lightest sticks, adding to each flower its peculiar green, and then grouping them together with a filling-up of Clematis, or of white Heath, or of something similar. White Jasmine is not amongst the most desirable, as the flowers drop so readily. A ground of Lilies of the Valley would, I think, look extremely lovely. White Violets would do tolerably, though a little too broken. White Lilac does very well; and double Chinese Primroses are only so far objectionable that they are a little stiff, and perhaps somewhat solid. I have seen white Azaleas, also, answer very beautifully. Perhaps Camellias, Azaleas, Lilies, and Orange blossom are of all the very best things to have; but it does not do to use Azaleas for the filling-up, or ground, unless they are smaller than the principal flowers used.

I will now proceed to give three or four separate designs, which may be done very shortly, taking for granted the explanations above.

1st. A perfectly white design. Centre Camellia, Azaleas gathered round it, but, yet put in lightly, and without trying to force a quite level surface, which is nearly impossible, and quite undesirable. Five more Camellias at intervals, mixed again with a few of the largest Azaleas standing lightly. A few Orange flowers may be interspersed, and then Lilies of the Valley, or white Heath, or Clematis. If the former, a few leaves of their own may be used, but they should be of the youngest and palest kind, belonging to roots which have not flowered, and should only just show their heads between the Lilies and their frame or case. If Clematis or Heath is used, the Orange flowers and some Lilies may be mingled with it; but in these snow white groups a very little green tells quite sufficiently, and no separate foliage need be used at all. The small pale green fronds of the Maiden-hairs could hardly, however, fail to add some grace and lightness whatever may be the centre.

In arranging all these flowers it is very essential not to cut off the leaves a little below the flower as far as they are good; they tend to keep the arrangement lighter, and also to obviate the appearance of unnaturalness in removing green.

2nd. White edged with blue. In this arrangement a little more green is to be admitted in the central part; it, also, will bear somewhat heavier flowers, such as the Double Primrose; and Banksian Roses look very well in this case. They ought, however, to be mingled with larger flowers—Roses or Camellias. The half-opened Gardenias and the delightful thick-petalled *Stephanotis* are amongst the most charming flowers that can be employed, either in this or any other case.

The last line should be of small broken sprays mingling with blue. *Lobelia*, *Forget-me-not*, small *Campanula*, and prettiest almost of all blue *Harebells*, may make this border, and break into a waving fringe of Fern. Where Fern is used the beautiful little *Harebells* seem to be quite at home, shaded by it and peeping out amongst it.

For a blush bouquet the smaller flowers should be quite white, and only a few half-open Roses tinted; or the flowers should be white with a very delicate mixture of the palest pink-tinted Rose buds. The *Multifloras* Roses are amongst the very best to use in this way, their long tapering buds having such a waxy look.

Many Camellias and Azaleas have the faint stripe or shade of rose I speak of. In these cases, of course, care must be taken to have a sufficiency of real snowy white, and so to arrange it as to make it harmonious.

In any case where flowering Myrtle is used it should be continued, or at least repeated several times. It is, however, rather too dark a green for a quite white bouquet, though, sometimes, the fresh shoots do well to mount other flowers upon.—E. A. M.

ARRANGEMENT OF CROCUSES.

Our garden lies behind the house, is of square form. As a relief, the wall has been built with a semicircular curve in the central portion at the back of the house, with curves at every corner, but there of greater depth. In the first, described as No. 1, east exposure, as well as in No. 2, south, I have placed three hives of bees. Observing the large quantities of pollen carried in by my winged favourites from a row of large Dutch Yellows, planted from corner to corner of No. 1, and that the ground around the hives is all the better to lie vacant during the summer, so that no shelter may be afforded to toads, snails, &c., besides affording free footing for inspection, under which pressure the roots do not seem to suffer after their withered straw has been removed. I have, therefore, determined to plant both hives entirely with these beautiful bulbs, excepting the shaded portions beneath the boards, and as they are to stand permanently, would like to arrange them so effectively that they may come up to that standard of perfection so requisite to please the critical Beatonian eye.

Having had the ground dug and prepared, I presume I must first and foremost start out the yellow row, and am then all ready to begin *de novo*. If I recollect, Mr. Beaton's idea was to plant in stripes or bands, decidedly superior in effect to the hotch-potch system. Now, in such spaces as I have described, whether it would be better to plant the band all of one colour from end to end—say yellow being strongest outermost, next

entire band white, and so on; or each band of mixed colours beginning—say with white, yellow next, white next, and purple next, &c. What length in that case of each colour, if I plant every band with the same colour opposite in its neighbour, would have the effect of throwing the whole into stripes of the different colours up and down, the bands or at right angles to the eye and walk. How would this look? or should I study to lay down the ribbons so that there may be always a different colour opposite in the row above? or what other mode could you suggest as an improvement? As they thicken quickly, I presume 4 inches close enough from bulb to bulb, and row to row. How broad should I make the bands, or rather how many rows of same colour? perhaps I might leave 2 inches more from band to band, than from row to row? I meant to plant with three colours only—large yellow, large purple, and white, eschewing Cloth of Gold stripes, and such early varieties so as to have them all in bloom at one time. Would the old pure white be better for effect than the large lights, such as Sir Walter Scott and Queen Victoria? Perhaps having all large they would bloom more evenly. If you recommended planting bands with broken colour, then, perhaps, I might put in for variety, different light ones as they came round, as Mammoth, Majestuse, &c.—SCOTTS.

[Your idea of a Crocus garden for the bees is capital, and that of planting them still better. Your plan No. 1, a half-moon, a little over 10 yards along the straight edge, and about 2 yards through the middle of the half-moon. On that, the centre axis, you have a hire, and there is one hire at the roots of the two horns of the moon. You look across the half-moon, not along from horn to horn, and the man in the moon himself could hardly err in planting such a space seen in such a way, with the only three colours in Crocus—white, dark, and yellow. The back and the two horns, or two angles, to be yellow—large Dutch, four rows in the widest part, then three rows as the space narrows, and two rows at the points and turn, the two in a volute of yellow back as far as the inner side of each live. Then your purple in the centre and white next the walk will be more on the square and look exceedingly well.

We would plant three kinds of white for the front, and three kinds of purple for the centre—say one Queen Victoria, two Sir Walter Scott, and three Mary Queen of Scots, which Mr. Paul exhibited last spring before the Floral Committee—that is, shaded white. The first row of purple to be the lightest—say Ne Plus Ultra; the second row Prince Albert; and the third row the darkest purple, which we forget just now, on purpose to allow yourself a choice, or take only one kind of white and one kind of purple. Your plan No. 2 will only be the same arrangement on a larger scale.]

PROTECTING PLANTS IN A GARDEN NEAR LONDON.

My garden lies east and west, having a wall on either side. I wish to know, if I have some wire netting hung from hooks on the wall facing the south, and covered with some kind of matting, whether that will be sufficient protection throughout the winter for such cuttings and plants as Geraniums, Fuchsias, Calceolarias, Verbenas, Lobelias, Pentstemons, and Antirrhinums? Also will the roots of *Lilium lancifolium* and *Amaryllis* keep securely in silver sand, or what is the best method of keeping them?

I have two Fuchsias in the drawing-room window facing the west, or perhaps more correctly S.W. by W. I was rather proud of them, they looked so healthy and robust. I have kept them in the same place all through the last winter (there is a fire in the room every day throughout the winter), and expected a good show of flower this season. But alas! I have been disappointed. One of them has had only about six blossoms on, and all on one side of the plant: the other not one or any sign of one. Can you tell me the cause of this and remedy?—G. S. N.

[We do not think your proposed plan would enable you to keep such plants as you specify, unless the weather in winter were to be unusually mild. Then you might save some things plunged in sawdust, if covered with waterproofed glazed calico to let in light, and with a stout woollen or padded cloth, waterproofed outside, to put on at night and on cold frosty days. We think all this would involve more trouble than a glass case, which you might cover in a similar way, and either help in

extreme cases by borrowing some heat from the house, or supplying with large earthenware bottles filled with hot water. Failing such means, we would advise keeping such plants in a room in which a small stove could be placed, or a fire be made in the fireplace with a damper in the chimney. The plants should stand on tables near the window on fine days and air be given to them; but in cold days and nights the shutters should be shut, and the tables be moved to the middle of the room, giving all the light possible when the temperature was a few degrees above freezing.

If the *Lilium*s and *Amaryllis*s are in pots, you could not do better than allow them to remain in them; and if the pots were set on the floor of a cellar at all dampish, the earth will need no water, and the bulbs may remain as they are until they begin to push, when they should be taken into the light, top-dressed and watered, and the best treatment that your rooms can afford given to them. If the bulbs are out of pots now and the roots mostly gone, you may keep them in sand as you propose in any cool place of the kitchen where they will not be too hot nor yet likely to be frosted; and as soon as they show signs of growth put them into pure loamy soil with a little leaf mould, using the pots small at first rather than large. Water sparingly until you see that growth is freely proceeding, and then continue watering until the leaves begin to change; then refrain, and winter in the pots as above.

The *Fuchsia* plants were growing too much and too long in winter, when there was not enough sun to ripen the wood. Unless there is the assistance of a hothouse to grow on young plants in winter to bloom in summer, older plants of *Fuchsias* do best when treated as deciduous plants that need a rest in winter. When we have tried to save large *Fuchsias* out of doors in winter we were always disappointed the following summer—they never bloomed so fine as those had pruned in or cut down the previous autumn. Keep your *Fuchsia* plants full in the sun now; give hardly any water, unless the soil is very dry and the leaves flag. When the leaves begin to turn yellow prune off part of the young shoots, and place your pots on the damp floor of a cellar, where they will need no water; or if in a garret, place damp moss or damp hay all round the pots, and in severe weather cover the tops with a little hay to keep the frost from them. In spring, as soon as the buds begin to break, examine the plants, prune back to the desired shape, place the plants in the light; and when the young shoots are a quarter of an inch long, shake away most of the old soil, repot in fresh, and give water in proportion to growth, and we feel assured you will have plenty of bloom in summer on your pet *Fuchsias*. If before fresh potting you were to dip the roots for a couple of minutes in clean water at 70°, you would not need to give water at the roots for some days; but if the days were sunny a sprinkle of clean water over the heads of the plants, such as you might shake from a dusting-brush, will do them more good. Do not over-pot or use too rich soil. It is better in your case to add a little rotten dung every fortnight or so to the surface of the soil, or just as much as you can hold between the thumb and finger of superphosphate of lime.]

LOBELIA SPECIOSA.

IN REFERENCE to an article that appeared in THE JOURNAL OF HORTICULTURE, of October 1st, page 6, we must take the liberty of correcting you respecting *Lobelia speciosa* being unknown to the seed trade. Of course, you are aware that the greater part that was sold last year was imported seed, as but little was saved in England, owing to the wet autumn; and we beg leave to state that we have just harvested two large beds of the true Crystal Palace variety of *Lobelia speciosa* at our seed farm, at St. Osyth, and we have now orders for the same from most of the principal seed-houses in the trade.—JAMES CARTER & Co., 237, High Holborn.

A NEW USE FOR APPLES.—We are threatened with a cider famine, not from the failure of the Apples, although a partial crop, but because they are likely to be applied to a more profitable purpose (so far as the growers are concerned) than in making a household beverage. It seems that the Manchester calico dyers and printers have discovered that Apple juices supply a desideratum long wanted in making fast colours for their printed cottons, and numbers of them have been into

Devonshire and the lower parts of Somersetshire buying up all the Apples they can get, and giving such a price for them as in the dearest years hitherto known has not been offered. We know of one farmer in Devonshire who has a large orchard, for the produce of which he never before received more than £250, and yet he has sold it this year to a Manchester man for £360. There can be no doubt that the discovery will create quite a revolution in the Apple trade.—(*Times*.)

NECTARINES SHRIVELLING, AND PEACHES FALLING OFF.

THE last two seasons—the first wet, cold, and ungenial, this present one altogether the reverse in this part of the country (Bideford), the Nectarines and Peaches on a south wall (stone) have not ripened; the Nectarines some two or three hundred as fine as could be seen coming to their full size, instead of maturing began to split and shrivel up, but not to fall off; and not one this year or last came to perfection. The Peaches, equally large and splendid in appearance, instead of ripening, one by one fell off; no trees can or could look more healthy, or fruit more beautifully; hence my surprise. The subsoil is clay. But, if it be the soil, why should the trees grow and prosper, always in vigour, full leaf, and plenty of new wood? The drainage is good, the soil they are planted in is 3 feet or 4 feet from the foundation in height, and the water infiltrates through, yet not a single Peach or Nectarine came to perfection, or catable either this or the past season; yet the weather each year could not be more different. Can any of your readers intimate a probable cause, and suggest a remedy?—J. C. H.

[It is difficult to assign a reason for such an extraordinary result, as we suppose everything necessary had been attended to. We should not have been surprised if such a thing had happened last season, as the fruit might be more glutted with moisture than they could well throw off by evaporation; and, therefore, splitting, and rotting, and falling off would be almost a natural consequence. If you have had as much dryness as we have had, such a result might have taken place from dryness at the roots. A similar result might also take place if the ground was thoroughly soaked, and a few very dull days succeeding after such a soaking. We noticed both cases in our experience. When the ground was soaked about the roots, and the weather dull and cold, the juices absorbed, did not find the fruit expanding to receive them; and the cracking of the skin was the result to give vent in the one case, and falling off in the other. Other trees similarly placed, only with a little heat applied to cause the fruit to expand with the absorption of the moisture, swelled off beautifully. On another occasion in a fine season like this, we found some cracking and falling as you represent; but on examining the soil down to the roots, we found it too dry; and, hence, there was not a sufficiency of moisture to meet the demands of the sun on the fruit. Some trees that were well watered escaped the evil. We have no reason to suppose that these were causes in your case, but we merely mention them as facts; and would be glad if some condutor or correspondent would try and throw more light upon the subject, as the fruit that did stand this season did, we believe, on the whole ripen well. There were few crops so good as yours. Even the blossom that appeared on our trees dropped to a great extent from the unripeness of the wood.]

FLOWERING DIELYTRA SPECTABILIS AND DEUTZIA GRACILIS IN JANUARY.

I HAVE some plants of *Dielytia spectabilis* growing in the borders which I intend to force, and would like to have them in flower by the new year. A hint how to manage them would oblige.

Can I have *Deutzia gracilis* in flower at the same time? and will the same treatment do for both?—BR.

[We presume the *Deutzia* is in pots; if so, keep them full in the sun, and give them a little water. About the first week in November top-dress them, and place them in a mild heat in November; if a little sweet bottom heat all the better—say top heat 50°, and bottom heat 70°. Increase the top heat gradually, so that at the third week it will be from 60° to 63°, and as soon as the flower-buds appear lessen the heat with more air, to make

the flowers robust and strong. You will have plenty of flowers if the wood is well ripened this autumn.

Take up the *Dielytia* out of the borders directly, save the ball if possible; but ball or no ball, use no bigger pot than you can get the roots in nicely, and pack sandy loam and a little leaf mould firmly round them. Then plunge the pots in a slight hotbed out of doors—say in a temperature of from 70° to 75°, leaving the tops exposed, but protecting from frost; and then in the second week of November treat much the same as the *Deutzia*, giving if anything more heat to encourage the flower-stems to rise.]

JOTTINGS IN NORTH DERBYSHIRE.

CLAY CROSS AND NEIGHBOURHOOD.

IN the last Volume of *THE COTTAGE GARDENER* appeared an article by "BEN BOLT," on Eecleston's Conqueror Cucumber, which, I believe, induced many to try that useful variety. Having lately been in that district and jotted down a few observations, they may not be unacceptable to your readers.

Clay Cross is chiefly known from its extensive coal mines and iron works belonging to Sir S. M. Peto, and others. There is also the Wingerworth Company, who have extensive works on the estates of the late Sir H. Hanley, and other pits of minor importance, yet employing many men. There is a building here in which are held the schools under an efficient master, and supported by the Clay Cross Company. Here are the Mechanics' Institute and Public Library, the latter containing, I believe, nearly 3000 volumes. Indeed, C. Binn, Esq., the manager, with liberality of spirit does all in his power to raise the intellectual and moral habits of the people, by supporting and sanctioning any scheme having for its object the permanent improvement of the working classes. With this end in view, there is held annually, the second Tuesday in August (the Wakes week), a horticultural and floral exhibition, in the grounds of the manager, when prizes are given, I understand, amounting to £200 or more. This season it has been decided by the Committee not to hold one out of respect to the feelings of the bereaved families of twenty-three poor fellows who lost their lives through the late melancholy inundation of one of the pits. The classes are as follows:—1st, For the men in the employ of the Clay Cross Company, vegetables, florists' flowers, window plants, and last, but not least, a prize of 10s. for the garden best cultivated and in the neatest condition. 2nd, Prizes varying from 8s. to 10s., for cottagers within six miles round on paying a small subscription similar to the above. 3rd, For amateurs paying a subscription, for vegetables, plants, &c. This is open to all England. 4th, For gentlemen's gardeners, with the usual class of prizes, open to all England. 5th, Nurserymen and market-gardeners, open to all. 6th, For farmers; 1st, for the best cultivated farm in the occupation of a widow farming a certain number of acres, a silver cup; 2nd, for tenant farmers, a cup. Then prizes for various cereals, roots, &c.

This has given a great impetus to the love of gardening. One is famous for his Pansies, another for his Fuchsias; one for *Dallias*, another for *Celery*; one for *Rhubarb*, another for Cucumbers; and it is a pleasing trait in the character of this Society, that the working men, many of whom are working down the pits and for months do not see daylight only on "pay Saturdays" (once a fortnight), and Sundays—yet these men and others who are occupied in various ways in the iron works and other departments, lead the tradesmen in horticultural matters. And to show still more the kindly sympathising feeling of the noble, large-hearted manager, with the well-known philanthropic spirit of the proprietors, a second exhibition is held in the autumn for men in the employ of the Company, when prizes are offered for the best autumnal garden productions. It is held in the school-room, and I am pleased to say the Exhibition held there last September would have put to the blush many of the "blue flag practicals." So are the concurrent opinions of censors and gardeners themselves who were there, some of whom were Southerners. Such is the enthusiasm with which they take up these matters, that frequently other Shows are held at the Gardeners' Arms Inn, for teapots, tenpots, &c. Another pleasing trait in connection with this affair, and at the same time showing the provident habits engendered by the introduction of horticulture, is seen in the number of Cucumber-houses, pits, and frames, which are increasing every year, and still may they increase.

While speaking of Cucumber-houses, I may as well here say,

that there are, perhaps, some of the best growers of Cucumbers in this district I have ever seen—far surpassing any I have seen among the professionals this season south of London. Some grow for sale and make a good profit on their outlay. Mr. Eccleston, gardener to C. Binns, Esq., is a sort of father among them, being held in great respect by all classes; if information or instruction is required, he is always applied to. I shall not attempt to describe the whole of the garden, but note his Cucumber and Celery. The latter was very fine when I saw it in July, nearly 37 inches high and 14 inches round. I did not see it surpassed among the growers even at Sheffield, and only equalled by one—viz., Mr. J. Limbs, of Sheffield Road, Chesterfield. The kind grown was chiefly Laing's Mammoth.

Here I saw and tasted the Conqueror Cucumber, which, in my opinion, has a fault or two. I certainly do not like the colour—it is too pale, and the shoulder is too long and small in proportion to the circumference of the other parts of the fruit; but for flavour and general cropping it is unequalled. Mr. Eccleston informed me, that by some means he found the fruit which he saved for seed had been impregnated by some other kind, as was proved by a plant growing by the side of another—one was true, the other had degenerated. He was very anxious lest some parties who purchased seed of him should have been disappointed or dissatisfied. If any should have had cause of complaint, I would advise them to communicate with Mr. Eccleston, as he has taken every precaution to save seed from a true stock and no others are growing near. He has a magnificent kind in bearing this season for the first time, which he calls Phenomenon. This will become a favourite with all growers, being free from ribs, a short square shoulder, beautifully spined. There is no coarseness about it; and the colour is good dark green, carrying a fine bloom. It is suitable for table, and is a good bearing kind. The fruit I saw was 24 inches long and still growing. I understood he purposed to send a brace of each to the Fruit Committee of the Horticultural Society this autumn.

The following notes of other kinds may be useful:—Mr. W. Walters had Hamilton's Black Spine, a coarse, deep-ribbed variety. Epps' Garibaldi, received direct from Maidstone. It is the most worthless thing ever sent out by the trade; it is no better than the Stockwood Ridge. Indeed, this season I have seen better fruit growing in the open air. Dreadnought carries a good bloom, is a good bearer, but a bad setter, has the longest foot-stalk, perhaps, of any grown kind. It is a strong, coarse grower, about 18 inches to 24 inches long. Eugenie is a kind, useful variety, and deserving of extensive culture. Webb's Improved Black and White Spines, received from an eminent firm in London, are condemned. Ewings' Waterwirth, a local variety from Godfrey's Black Spine, is a good, square-shouldered kind, very prolific, and requires a strong bottom heat to grow it well. It will be a good kind for market purposes. Barlow's Prolific still holds its place among the good ones.

Here I saw a useful kind of house lately built by Mr. Joseph Holland, a blacksmith, fitted with hot-water pipes for bottom and top heat, and heated with a small boiler, which must be called, I think, "Holland's Cottager's Boiler," a description and cost of which I will forward to you on receiving permission from him to do so. It is simple in its construction, effective in its work, moderate in price, and does not require much attention, and to judge by the look of the plants growing there it was all that could be required.

The effect of the late winter was very plainly seen. Oaks, Common Hollies, Aucubas, Laurels, and even Portugal Laurels killed to the ground in many places. Some of the latter at the residence of the late G. Stephenson, Esq., Tipton House, of, perhaps, forty years' growth, had their south sides killed; while at Hardwick Hall (the Duke of Devonshire's), the only plant hurt appeared to be Pinus insignis. There is scarcely a standard Rose to be found alive. One of the most notable places is, perhaps, Kingwood, at Stavely, the residence of R. Barrow, Esq. The gardens lie on the south side of a bill. Advantage has been taken of this to form a series of terraces. There are some excellent houses here for Peaches, Vines, and plants; two conservatories, in one of which are some excellent Acaecias, particularly *A. grandis* and *A. pubescens*. There are also six new vines being erected here at a cost of £3000. The borders are covered with glass and heated with hot-water pipes. They are erected by Meredith, of Liverpool, I believe, and are of a substantial character.

I have not time to touch on Chatsworth, the "Palace of the

Peak," or some other places. Fruit is exceedingly scarce in the district. One other note I find—viz., the Potato called Chatsworth, a second early kind and very productive. Mr. S. Low, of Tipton, is growing this season a large breadth of them. It is a fine, dry kind, and not so liable to disease as some others, generally ripening ere the electric storms come on.—NICKERBOB.

POTATO CROP IN IRELAND.

It appears from the tables published annually by the Registrar-General that the yield of the Potato crop last year was smaller than in any year since the famine, though, with the exception of 1859, the quantity of land devoted to the crop was greatest of all. In 1847 it was, in round numbers, 28,000 acres; in 1850 it was 117,000. Yet, strange to say, the produce was nearly as great in the former year as in the latter, it being per statute acre fifty-seven barrels in 1847, and only eighteen barrels in 1850. This shows that the impression that the Potato was gradually recovering its former healthy condition is a mistaken one—in fact, it has been rather degenerating since 1847, the year after the general failure. This does not prove that the crop cannot be restored; it only proves that the means employed to restore it while the panic lasted have been unaccountably neglected. Potatoes got into a state of decay from causes that produce the decay of any other crop, and these causes are preventible. The farmers reverted to the use of worn-out degenerate seed, which they committed to worn-out soil. A proper selection of foreign seed and of fresh ground for the crop, due care in draining, cultivation, and weeding, all of which were anxiously attended to with the best results in 1847, would have produced similar results ever since, had not the farmers relapsed into their old lazy feeling of security, for which they are now again likely to be severely punished.—(Times' Correspondent.)

WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from page 30.)

CRUSTACEA—(continued).

THE COMMON SPINY LOBSTER (*Palaemon vulgaris*).—On the western and southern coasts of England this strange specimen may be found in considerable quantities, and large numbers are despatched to the London markets. Its flavour is not considered equal to that of the common Lobster; still it has its admirers, by whom it is held in high esteem. This creature derives its name from the fact of its shell being covered with spines of various sizes. It is ten-footed, like others of this class; the first pair of feet in the male strong and robust, in the female smaller and weaker, but in either sex shorter than the rest, and having but one claw or finger furnished with tufts of hair. The remaining pairs of feet are all one-fingered also, and likewise tufted with hair. The eyes are large and globose, the external antennae are extremely long, and have a strong, thick, spinous peduncle.

The length of the Spiny Lobster is about eighteen inches, measuring from the front of the shell to the extremity of the tail, and its colour is usually a purplish-brown, spotted with a dull white. The legs are a reddish-white, having longitudinal bands of reddish-brown.

THE NORWAY LOBSTER (*Nephrops norvegicus*) may be passed over with but slight mention; for although it is occasionally met with on the coasts of Scotland, it must be looked upon as a still more northern species, the largest quantities being sent, as its name implies, from Norway. It is a very beautiful creature, measuring about seven or eight inches in length, of a pale flesh colour, rather darker in some parts than others. The segments of the abdomen are highly sculptured; the raised portions being smooth and polished, the depressions covered with thick, short, downy hair.

It is said that the Norway Lobster has been taken off the Irish coast, as well as the Scotch; but its appearance is comparatively rare, and it is very unlikely to come under the notice of the ordinary tourist.

THE COMMON RIVER CRAWFISH (*Astacus fluviatilis*) has strictly speaking no claim to our notice at all, inasmuch as it is an inhabitant of our rivers and large streams, and, therefore, no resident on the seashore. It has a rough, scabrous shell. Its anterior pair of legs are thick and rounded, slightly spinous. Its colour is a dull greenish-grey.

We now proceed to an examination of the Crab tribes, distinguished from the Lobsters by being short, instead of long-tailed; both species, however, are ten-footed.

THE LONG-LEGGED SPIDER-CRAB (*Stenorhynchus phalangium*).—This is one of the commonest of the small Crabs, and is found on nearly all parts of the coast. Professor Bell states that he has obtained it from Wales, the coast of Cornwall, Devonshire, Dorsetshire, and Sussex, from Scarborough, and from Orkney. He also states, on the authority of Mr. Hailstone, that "it is very common at Hastings, both among the rocks on the shore, and in deep water, and is occasionally caught in the trawl-net in vast numbers. Of sixty-eight specimens brought up at once, the proportion of males to females was as two to one."

The shape of the shell is triangular, the posterior angles being rounded, and the anterior surface furnished with a few spines. The first pair of legs are strong and hairy, and about twice the length of the body. Each hand has two fingers, one of which is moveable. These feet are smaller in the female than in the male; the remaining pairs of feet are very slender. The Spider-Crab is sluggish and timid; moves with very little animation, and dies very quickly on being removed from the water.

THE SCORPION SPIDER-CRAB (*Inachus dorsetensis*).—So called from its being found in the greatest numbers on the Dorsetshire coast, particularly at Weymouth. The shell of this specimen is also triangular and swelling; the angles rounded posteriorly, the anterior pair of legs strong and thick, and of some length; the others considerably longer, and very slender; the second pair is the longest, being more than three times the length of the body. This species is very widely distributed. Professor Bell says:—"I obtained it in Studland Bay, Dorsetshire, and at Hastings. Mr. Couch states that in Cornwall it is commonly taken in crab-pots, within a few miles of the shore at all depths. And Mr. Eytton informs me that it is found on the oyster-beds at Rhoscolyn, near Holyhead. In Ireland it has been found in many places in the harbour of Cove, in the loughs of Strangford and Belfast, and in Dublin Bay. It is also recorded that Captain Beechy, R.N., brought up a specimen of this species alive in the dredge, from the depth of one hundred and forty fathoms, in the mull of Galloway."

THE FOUR-HORNED SPIDER-CRAB (*Pisa tetraodon*).—These

Female.

creatures may be met with in considerable quantities among the rocks at Bagnor, and other places, concealed under the hanging vegetation; the shell is triangular, posteriorly round, and entirely covered, as well as the limbs, with close shaggy hair—the first pair of feet is extremely strong and thick, the hands nearly as broad as they are long, and two-fingered, the fingers meeting at the points; the remaining feet are only of moderate size and length, the second pair being about as long as the creature's shell, and the fifth not so long as the shell is broad. Beneath the hairy covering the shell is polished; the colour is a dull reddish-brown, which, on becoming subject to the action of spirit or boiling water, turns to a bright red; its usual length is a little more than two inches in length and one in breadth. There are several tubercles on the surface of the shell, and the beak is formed of two strong horns. This creature, like the rest of its species, is timid, lazy, and slow-moving, from which latter cause it is frequently covered with minute marine plants, which flourish among the roots of its shaggy coat.

HYAS ARANEUS.—This is a species of Spider-Crab, which, according to Dr. Leach, "very common on the coasts of Scotland

and Kent; on the shores of Devonshire it is of rare occurrence." Professor Bell says:—"I have received it from Worthing, in Sussex, and from the coast of North Wales. I have obtained it at Hastings where it occurs in considerable abundance, and dredged it on oyster-beds at Sandgate of large size, at from ten to twelve fathoms."

The Hyas araneus is almost the largest of the Spider-Crabs, measuring somewhat over three inches in length, and two in breadth; whilst the anterior legs are upwards of five inches long. The shell is of a triangular shape, rather elongated; the posterior portion being rounded, it is covered with small tubercles; but both shell and limbs are entirely destitute of spines. The creature, however, is covered with a thick, shaggy coat.

THE SPINOUS SPIDER-CRAB (*Mais squinado*).—This Crab

is found in considerable quantities on nearly all parts of our southern and western coasts, and is the largest of the species, measuring sometimes eight inches in length, and six in breadth, the foremost pair of legs reaching a length of fifteen inches. The shell is convex and somewhat oval, getting, however, more triangular in shape as it increases in size. The shell is covered with countless tubercles and sharp spines. The anterior pair of legs much longer and larger than the rest. A quotation from Professor Bell, with regard to this and other Spider-Crabs, may be entertaining:—"Like all other triangular Crustacea, the fishermen inveterately term it 'Spider,' and they appear to have very little idea of any affinity between these forms and the Crabs properly so called. I remember some years since seeing in one of the back streets of Poole, near the water side, a little girl standing by a small table, on which was a plate containing two of these Crabs of moderate size, cooked, and for sale. On my accosting her with 'Pray do they eat these Crabs here?' she replied with a look of great surprise at my ignorance, 'They be't Crabs, sir, them's Spiders!'" As an astonishing announcement with regard to the fecundity of the Spiny Spider-Crab, we may also quote the Professor, who states on the authority of Mr. Couch, that a specimen of ordinary size will bear at one time upwards of seventy-six thousand eggs.—W.

(To be continued.)

CULTURE OF THE BANANA.

I HAVE a young plant (arrived a few weeks ago from Egypt) about 3 feet in height, and with two leaves each about 18 inches long. Will it require heat through the winter, or will it do in a greenhouse heated just sufficient to keep the frost out? I can put it in ainery during summer. Please also state what sized pot, what sort of soil, and what quantity of water it requires.—J. D.

[If your Banana is one of the strong-growing and lofty kinds you will do little good with it either in a greenhouse orinery. If a dwarf sort like *Musa Cavendishi* you might grow it in theinery, if thatinery was rarely below 45° in winter. You can only succeed with your young plant by placing it in the warmest corner near the heating apparatus either in the greenhouse orinery, and surrounding the pot with moss or tan, so as to keep the roots warm. At present it will be best to put the plant in a pot rather small than otherwise, using fresh fibry loam and a little

and to encourage rooting. As the heat in your vinery gets up the plant will then need another pot, and you may add some wet rotten dung or leaf mould to the compost. These, properly speaking, are all tropical plants, and though they may live they will not thrive under common greenhouse treatment: hence the recommendation as to the warm place in winter. In the first winter, if the pot is plunged, little water will be wanted. As the leaves grow in summer, and plenty of heat can be given, water will be needed liberally.]

PROPAGATION OF A STRAWBERRY BY ITS FRUIT STEM.

I HAVE a Sir Harry Strawberry plant in a pot which I rooted late last summer, by way of experiment, from a fruit-stalk. I just cut off after the fruit had been gathered, and pegged it into a

pot the same as a runner. The little plant has fruited the whole of this summer. I picked off the last ripe Strawberry this morning, and cut off another truss of blossom for fear the plant should be exhausted. It has been kept in the sitting-room, and placed outside the window when the weather was fine. Would you advise me to re-pot this plant? the pot it is now in measures inside 5 inches diameter at the top. Only two runners have made their appearance in June, which I cut off.

[Did you really root the stalk which carried the flowers and fruit in 1860? If so, did it make leaves? and, if it did make leaves, which part of the stalk did they come from, and what part of the rooted stalk did the two runners come from? We have no doubt about advising you to keep the pot just as it is till the fine weather in the spring causes the plant to make a fresh push: at that time we would shake off all the old soil, and replant it in fresh soil in the same pot. The fungus you enclosed is *Geoglossum glutinosum*.]

SEDUM CARNEUM VARIEGATUM (SIEBOLD).

THIS is a new Japanese plant; highly interesting and beautiful, of a succulent suffruticose dwarf habit, with compact branching

growth, the first radical shoots sub-erect; afterwards decumbent, and drooping. The numerous slender round stems are of a light pink, or a flesh-colour, clothed with numerous lance-shaped green leaves, edged with white on the parallel margins, and by full exposure to light the plant assumes a beautifully variegated silvery tint. Its close growth adapts it for either conservatory, or open-air summer culture. By its very free habit and ready increase, it will be found an admirable plant for front row effect in ribbon lines and flower-beds, or for decorating the summits of small fancy stone-mounds, diversifying the effect on larger masses of rock-work during the

summer months, and equally suitable for covering the surface of dry, warm, gravelly banks around terrace slopes, or pillar

bases. It is also a valuable plant for marginal effect around large vases and rural baskets; whilst in greenhouse-conservatories it appears to great advantage for permanent effect in baskets, vases, &c., suspended by brackets from the side walls.

For pot culture it thrives in all ordinary light sandy loam soils, and for open-air beds or borders it luxuriates in a mixture of one-fourth finely broken or sifted gravelly sand or brick-compost.

In autumn it should be re-potted in masses for house-decoration throughout the winter.

It is introduced by Messrs. Henderson, of the Wellington Road Nursery, St. John's Wood, London.

GROUND VINERIES.

I MUST decline the honour of having invented the "ground vineries;" my idea was merely to cover a space with slates, and place over this a Cucumber-light. My gardener suggested the frame and the furrow. The original idea, if it was an original one, I never carried out, as I heard of a person who covered a part of the wall of his house with slates, and trained Vines against them, which did not ripen their fruit so well as against the natural wall.

To Mr. Rivers is due the credit of ripening Grapes on slates placed on the ground under glass, taking advantage of the

earth's heat to assist the ripening. This answers thoroughly, as I saw the Grapes last week at Sawbridgeworth well ripened, and perfectly black. I would suggest an alteration to this plan, embracing all the advantages with some little improvements. I would measure out plots of ground—say 100 feet long by 6 feet 6 inches wide. I would take a spit of earth out on each side sufficient to raise the plot into a slight ridge. This is to answer three purposes. First, the trench would keep the plot high and dry; second, it would bring the ridge nearer to the hands in thinning, &c.; third, it would cause the distance between the

lights and the earth to be even. In the centre of the ridge I should drive in small charred posts every 3 feet, leaving them out of the earth say 15 inches. On each side of the ridge I should place the largest slates, side to side, leaving a space of 1 foot between the rows of slates in the centre of the ridge, and a space of about 10 inches on the outside. On these slates I should place the canes, arranging each plant so as to be able to add to the case as required. On the top of each post I would fix a staple, so arranged as to be able to fit a hook into it, by which the lights are to hang. These lights should be about 4 feet by 3 feet, and placed on each side of the ridge, suspended in the centre by the staples. On the outside they may be raised by stumps, and let down at night if required. (This case I think might do for forwarding Strawberries, &c.) Any gardener could make these lights. I should think that the top and bottom might be made of flat pieces of wood, to which the bars might be nailed; a little marine glue, probably, might here be useful; the bars might be grooved to admit of small squares of 16-cz. glass, 1½d. per foot, being slipped down without laps. The frame might be saturated with boiling coal tar six months before wanted, and if the glass be slipped into the grooves before dry there would be no occasion for putty. The lights might rest, probably, on bricks, and the ends be stopped with the same. I think these plots should run north and south. The Vines grow very luxuriantly in these cases, so that all superfluous shoots should be kept under to assist the effects of sun and air.

I have given rather a rough sketch of my plan, I hope it may be understood. Professional duties do not now admit of my paying much attention to these matters.

I am not quite certain that we could not cause plants to grow all the winter by taking advantage of the earth's heat—a plan successfully adopted by Mr. Rivers during the severe frost of last winter, when, by merely laying the pots with plants on one side and covering them with mats, he prevented the confined air cooling down to the freezing-point. I think that if a case were constructed somewhat like the one I endeavoured to describe above, with the addition of double glazing—i.e., with a space of a quarter of an inch between the two glasses to contain motionless air, which is about the best nonconductor, the heat radiating from the earth would not only prevent the air cooling down to 32°, but would keep the temperature considerably above this; it would be interesting to test the temperature under different degrees of external temperature. During the day, particularly in sunlight, the plants would no doubt grow, even if sufficient air be admitted, and at night, if shut up early and closely, the temperature, excepting in severe weather, would not, probably, be below the growing-point. A cheap porous material would answer very well for the frame of the lights and also the sides where the lights would rest on, this being saturated in a mixture of boiling coal tar and linseed oil, or creosote (6d. per gallon), the preparation used for steeping the ends of hop-poles, would act as a good nonconductor. The bars of the lights could be double grooved, and each bar being under-notched could be nailed to the cross-bars, forming the top and bottom of the light. These cross-bars should be 3 inches wide by 1 inch thick, the double-grooved bars being 1 inch wide and 1½ inch deep. Each pane of glass should be 15½ inches long by about 10 inches wide. The joint between the upper panes might be secured to prevent drip: probably this might be effected with liquid glass, a receipt for making which appeared in the *Field* newspaper a short time since, which might prove a useful article in all cases of fractures. How would Chaumont Pears, on the spur system, do in these cases, each case holding five rods? If extra heat were required, as there would be no radiation, I should say that one pipe 1 inch in diameter would be sufficient.

—SCRIBATOR.

ROYAL HORTICULTURAL SOCIETY.

FRUIT COMMITTEE.—The Committee met on Tuesday, October 8th. Mr. Edmonds in the chair.

A report of the Oxfordshire Committee was received from Mr. Bailey, the Chairman, which was read and highly approved for the interesting information it communicated.

Mr. Whiting, of the Deepdene, was the only competitor for the prizes offered for Pears and Plums. In the former class he exhibited *Bourré d'Amanlis*, *Jersey Gratioli*, and *Brown Bourré*, to which a Second Prize was awarded. In Plums he exhibited *Ickworth Imperatrice*, *Coe's Late Red*, and *Coe's Golden Drop*, to which a First Prize was awarded.

A very interesting collection of Grapes was received from Mr. Thomson, gardener to Mrs. Dixon, Stanstead Park, near Emsworth, Hants. The object of this exhibition was to show how the different varieties succeeded in an orchard-house and in other houses without fire heat, and how superior the Black Hamburgh is for this purpose over all the other varieties. The bunch of Black Hamburgh was large, well set with large, well-coloured berries, which were excellent in flavour. *Grove End Sweetwater*, well ripened, and small bunch. *Muscot of Alexandria*, acid. *Espérone*, a long, loose bunch, small round berries with squally flesh. *Golden Hamburgh*, a small bunch badly set with small berries, which were rather sweet. *Muscot Hamburgh*, bunch well set, berries small, with only a trace of muscat aroma, and rather acid. *Royal Muscadine*, large bunch, loosely set with small berries of good flavour.

Mr. Whiting, of the Deepdene, exhibited a bunch of a black Grape, name unknown. It was densely set with jet black, oval berries of good size, and a very tough, thick skin, but the flavour was rather watery and not remarkable.

Mr. David Thomson, gardener at Archerfield, near Drem, N.B., sent a bunch of a white Grape of high character. It was well set, the berries of a fine amber tinge, oval, and of good size, and with somewhat of a muscat aroma in the rich sugary and sprightly-flavoured flesh.

Mr. Thompson, of Stanstead Park, also exhibited a dish of very fine specimens of *Salway Peach*, finely grown and beautifully coloured. In flavour they were infinitely superior to those exhibited by Mr. Durrillhouse at the last meeting of the Committee.

A seedling Pear was received from Mr. Ingram, gardener to Her Majesty, at Frogmore. We believe it was raised from seed of *Marie Louise*. It is called *British Queen*, and is most appropriately and worthily named. The fruit is large and pyramidal, of a fine golden yellow colour on the shaded side, and covered with a crust of fine cinnamon-coloured russet next the sun, and with a blush of rosy crimson. The flesh is firm and not crisp, very juicy and melting, sugary, and with rich brisk flavour, and a fine aroma. This was awarded a First-class Certificate.

An Apple, supposed to be a seedling, was received from Mr. Davis, of Colechester, which proved to be *Hollandbury*.

Three extraordinary specimens of Northern Spy Apple, were sent by George F. Wilson, Esq., Gishurst, near Weybridge. They measured 14 inches in circumference, and their aggregate weight was 36 ozs. They were grown in pots; the fruit set in an orchard-house and ripened out of doors in the open air. They were not quite ripe, and, therefore, the flavour could not at present be determined.

Mr. John Spencer, of Bowood, Chairman of the Wiltshire Committee, sent an interesting collection of Apples from the valley of the Severn. They were principally cider varieties, but some were very large, fine culinary Apples.

Mr. Newton, gardener to J. G. Graham, Esq., East Lodge, Enfield Chase, exhibited excellent specimens of Apples—*Ribston Pippin*, *Margil*, and *King of the Pippins*.

Mr. Turner, of Slough, exhibited very long pods of *Dolichos sirenais*.

Mr. Edmonds, of Chiswick House, sent two roots of an immensely large Turnip Radish, as large as a field Turnip. It was a new kind introduced from Madagascar, by Dr. Erasmus Wilson.

Mr. Cook, of Chiswick, sent plants of *Brussels Sprouts* grown from home-saved seeds, and they were quite equal in quality to any raised from seed of foreign growth.

FLOREL COMMITTEE.—A Special Certificate was awarded to Mr. Rogers, gardener to S. Noble, Esq., Berry Hill, Taplow, for some very splendid specimens of the flowers of *Bignonia venusta*, so superior as a stove climber. Messrs. Veitch & Son had a similar award for that exquisite little variegated plant *Eriocnema marmorata*; Messrs. Henderson & Sons, Wellington Road, for *Pompeia Dahlias*; and Mr. Ivory, of Dorking, for Ferns.

First-class Certificates were awarded to the following:—Messrs. Veitch for the very ornamental variegated *Cyperus alternifolius*, the elegant *Palm Calamus australis*, and the handsome *Aloecia macrocarpa variegata*; Mr. Bull also for *Cyperus alternifolius*; to Messrs. Osborn & Son, Fullam, for some silvery-marked *Arctostichilus* and some *Oreolids* from South America; to Mr. Daniels, gardener to the Rev. C. E. R. Keene, of Swyncombe House, for *Bougainvillea glabra*, not so handsome but more easily grown than *B. speciosa*.

There were many other interesting plants exhibited, but none which received a Commendation except Miss Henshaw, a creamy white *Dahlia* from Mr. Henshaw, of Handforth.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Carrots, tie up for blanching when the leaves are quite dry; twist haybands round to prevent the earth from coming in contact with the leaves when earthed up. *Cabbages*, continue to plant out strong plants for Coleworts, and a succession of the best plant for standing as spring Cabbages. Prick out a quantity on a border or other convenient situation as a reserve for filling blanks that may occur through the winter, and for planting successions in spring. *Cauliflowers*, continue to prick them out under hand-glasses and in frames as they become fit to land. Any that are now fit for use to be preserved in a cool place. *Celery*, take advantage of favourable opportunities for earthing it up, see that it is quite dry; the leaves to be kept together, and the earth to be applied in a pulverised state. If attacked by the fly, dredge it with soot and charcoal dust. *Herb-beds*, fill up and dress them for the winter. *Onions*, those that are stored to be looked over occasionally, and the defective ones removed. *Potatoes*, continue to take up the main crops, the weather at present being exceedingly favourable for the purpose. As it is but rarely that we have such a favourable season as the present for digging and trenching ground, and as there are but very few gardens but would be benefited by trenching, we hope the fine weather will not be allowed to pass over without attention to this beneficial operation.

FLOWER GARDEN.

Scarlet Geraniums, *Fuchsias*, &c., which it is intended to winter for use next season, to be taken up immediately and placed in a gentle bottom heat for a short time, to excite the roots to establish themselves in their pots; they should not be cut back, but should be kept over the winter just as they are lifted from the beds, and cut back only in the spring after starting them into growth, when the cuttings will root very freely in heat, and will make good-sized plants by turning-out time.

FRUIT GARDEN.

Continue to collect and store away the late varieties of Pears and Apples carefully, and see that those already stored are in good condition. When Walnuts have been collected and sweated for a week or ten days in a heap, then cleared of their outward covering and shaken in a sack, should be placed in earthen pans that are quite dry and not glazed, and to be covered with a piece of canvass or thick brown paper, and about an inch of dry sand over them; to be stored away in any moderately dry place; and when required for use, in succession, to be placed for eight or ten days in a damper situation, which will freshen them and cause the inner skin to peel off freely. Run a soft broom over the Peach and Nectarine trees with great care, to take off just the very ripest of the leaves. The present is the most favourable time for lifting and transplanting very vigorous unfruitful trees on walls. Apricots, Peaches, and Nectarines may be so treated with great advantage, and after the operation is performed they should be well mulched with short litter to protect the roots from severe frosts. Fill up all vacancies on the walls with young trees; never let this be left until the spring if it can possibly be avoided.

STOVE.

A temperature of 65° to 70° by day, and 60° by night, will suffice, still using a somewhat moist atmosphere in the afternoon and during the night, with a free circulation of air, keeping also a little ventilation on at night. As some of the Orchids become ripe, such as the *Catasetum* family, the *Cycnoches*, *Lycastes*, &c., they may be removed to a drier and somewhat cooler atmosphere. Pursue a kindly course of treatment with the *Euphorbias*, *Gesneras*, and such things for winter blooming; these will soon be of great service. The *Platys grandiflorus* with the *Stenorrhynchus speciosus* will soon begin to bloom; also the *Cypripedium insigne* and *venustum*. Let them have plenty of heat and moisture.

FORCING PLANTS.

All plants for this purpose to be got under cover if possible, placing them either in cold pits or making some temporary protection for them. Roses may be pruned and regulated, and the same of Lilacs. *Rhododendrons*, *Azaleas*, and other American plants to be potted without delay. Plunge all the pots in tan, or some other light material, and that before the frost has destroyed the outer roots.

GREENHOUSE AND CONSERVATORY.

Water, when necessary, to be given early in the day, so as to

allow the superfluous moisture to be dried up before night; for damp among flowers at this season is more injurious than a moderately low temperature. On cold, dull, foggy days it will be advisable to use a little fire heat, with air during the day, so as to secure a moderately dry state of the atmosphere before night. The early-flowering *Chrysanthemums* that have for some time been staked and placed inside some structure will now be showing their bloom-buds, take care that they are thinned in due time, as a few well-formed blooms are to be preferred to many inferior and defective ones. By this time most of the specimen plants will have been securely housed. The conservatory will now become the principal feature of attraction for the winter, and to this house every plant which has a bloom upon it must be removed. Look the *Camellias* over, and thin out the flower-buds where necessary. The leaves also, if dirty, to be washed perfectly clean, and the same of Orange trees. Above all things keep a sharp look out for insects. If worms are observed in any of the large pots water them with clear lime water. The specimens on the walls and in the borders to be examined at the roots, and, if necessary, to receive a gentle soaking of weak, clear, liquid manure.

PITS AND FRAMES.

The rooted stock of *Verbenas*, *Heliotropes*, &c., to be well attended to, keeping them clear of green fly, and exposing them freely to the air on every favourable opportunity, so as to prevent growth as much as possible after this time, and to keep the plants hardy, in which state they will be much less liable to fog off under a week or two's confinement in winter.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

CLEARED away all decayed leaves from Cabbages, grub-infested leaves from Celery, running heads of Lettuces; and hoed and watered Endive, Lettuces, and a late crop of Dwarf Kidney Beans just setting and swelling nicely, which will have the protection of sashes placed over them, and a little straw over the sashes if a frosty night should come. These Beans come in very useful after those in the open ground are destroyed. Watered Scarlet Runners well, as the pods seemed to refuse to swell owing to being so dry at the bottom. Frequently run a rough straw band through the stakes, longitudinally in the row and near the top of the stakes, which often saves this valuable vegetable from the first frost. Late Peas are often prolonged by the same means. Find they are very good as yet. Thinned the last sowing of Turnips. Made another sowing of Radishes on a sloping bank, on which a two-light box can be placed by-and-by, and ere long will sow in a slight heat in a frame. Lifted the earliest Carrots, as, if longer in the ground, they are apt to be affected with the worm, and it is a good thing to have several successions, the young Carrots eating so much more sweet and crisp than older ones. Finished large brick tank, cemented to catch the water from orchard-house, as water is a matter of great importance with us. Strung and hung up Onions on every favourable opportunity, when from heavy fogs or drizzling rain the ground was too greasy to be comfortably worked upon.

FRUIT GARDEN.

Kept moving off every vestige of a runner in the *Strawberry pots*; and whenever rain threatens to be continuous will move them under protection from wet at least. Glass is best for this purpose when it can be spared, with plenty of air back and front, such as the floors of common orchard-houses; and in default of these the pots might be built in stacks to throw the water past them, or plunged in beds, and any simple means adopted for throwing past them the heaviest rains, and saving them from the severest frost. A little frost at the end of October, or about the third week, does good rather than otherwise, as it arrests all growth; and if any little sun reaches them after that it helps to more thoroughly ripen the buds. We frequently see *Strawberry-pots* standing out at Christmas exposed without the least protection, and soil and pot frozen as hard as a cannon ball. Need we wonder that fibres are snapped, and that pots are broken by such exposure, and that the best-looking plants disappoint the grower in the little fruit they render afterwards? The least such plants deserve is to be plunged, and the surface covered with some non-conducting substance, such as straw, to keep out severe frost. If in addition to this they

be protected from rains and snows from November to March, the early forcing part will pay for all the trouble in more plentiful productions. Watered the plants pricked out in the border to be raised in March and April if wanted for forcing. They will do well at that time. For early forcing two things are essential—firm potting, and the pots full of roots and the buds getting ripe before the middle of October. For expediting that ripening we do not like our pots to be plunged when growing; but we would resort to plunging or any other means to keep severe frosts and heavy rains from the plants and pots, after the middle of October.

Some Figs in pots, not likely to ripen their fruit in a cold house, have been removed to a pit, where fire heat can be given to perfect them. Unless the autumn should be fine, it is rare that Figs are worth eating after the third week in October. The same may be said of Melons. Have cleared most of ours out, and placed fruit worth keeping in a warm place in a vinery. Have smoked the vinery with a little tobacco, bruised Laurel leaves and a few Capsicums cut into pieces, as the thrips was making its appearance—a nuisance we got some years ago, by placing some Azaleas there to help them to make their wood more freely and early. Removed all plants from the late vinery, and raked the floor that all might soon be in a dry condition; and looked over the bunches, to see that no diseased or rotting berries were present to affect their neighbours. A little fire will be taken on most days and air given freely, the air never being put all away at the back except during a frosty night. Peach trees and Apricot trees have been gone over and every lateral removed, the longest shoots shortened, the ripest leaves brushed off, and those yet quite green shortened in their length, that the sun might have more free access to the wood and buds. Some Vines in pots, put in too late to fruit much next year, have been put into a pit, where they may have a little fire heat to ripen them at the base.

ORNAMENTAL GARDEN.

Means will be taken soon to remove all Fuchsias and things of that kind from the conservatory, and to fill with Azaleas, Camellias, Epacris, Citisus, Cinerarias, Primulas, &c., and by-and-by with Chrysanthemums. Chrysanthemums should now receive what tying and regulating they require, and be watered with manure water; and where very large flowers are desired have some of the buds thinned out, and be protected from sudden frost, or any lashing, heavy, cold rains. *Salvia fulgens* and splendens will also come in well as contrasts; and if the conservatory ranges at night from 45° to 50°, *Gesnera zebrina*, *Euphorbia jacquiniiflora*, and *Poinsettia pulcherrima* brought on elsewhere will bloom well in the warmest end of the house. A few late Fuchsias may also still be retained; and the *Fuchsia serratifolia* is a fine winter-flowering kind, and contrasts well with such plants as *Justicia carnea*, *faricoma*, &c.

Neapolitan and other *Violets* should now be potted or planted in beds under glass for the winter. If the situation is warm and the ground light and sandy, the *Neapolitan* does well planted out in sandy loam and leaf mould. In cold places, where early and continuous gathering is desirable, it is best to build a bed of dryish litter and a few leaves, just to be raised 2 feet or so from the ground, and to yield the mildest possible bottom heat. The use of the bed being more to enable linings to be applied to throw in a little heat in cold weather than for the purpose of getting much heat now. Every runner should be carefully removed, every leaf at all withered or showing signs of mildew; and if traces of mildew or red spider should appear, every plant whilst held in the hand should be dusted under the leaves with a mixture of sulphur and bruised charcoal. In planting, water as you go, so that the dry soil may be on the surface of the bed; and this end also painting the back and ends of the frame with sulphur will generally set the last vestige of red spider adrift. In potting, put the fresh loamy soil firmly round the plants, and do not use pots larger than will let the balls conveniently in.

BULBS.

We have not done much with bulbs of late; but the sooner those who intend growing them obtain them the better it will be; and if not convenient to pot them or plant them, the bulbs may be placed anywhere under protection in sweet, kind soil, covered over, and neither potted nor planted out until they begin to grow. This is the best plan for those contemplating beds of Tulips, Crocuses, Hyacinths, &c., in the flower garden. The beds may remain a little longer in their summer garb, and when the bedding plants are removed the beds may be properly

digged, and every attention paid to get the ground in the kindest possible condition for the reception of the bulbs, whilst the bulbs are all the time making progress in your reserve garden. A little good rough leaf mould should be mixed with the soil in which bulbs are placed for this temporary purpose, as then they will lift with little balls, and never feel the removal, but will strike away into the nicely-plastered soil at once. This is better, much better every way, than making holes in a hard bed in which to insert the bulbs before it is possible even to dig the bed on account of the crop it now contains.

BEDDING PLANTS.

We can add little to what was said last week. With a little mild bottom heat, and air left on, almost everything may be struck between this and the end of October, and will stand in little room in winter. For this we chiefly use what are called 60-pots, a third filled with drainage, and the rest with sandy loam, and for small things a little white sand on the surface, with one row of cuttings close to the edge all round, and the points of the cuttings pointing inwards, so that the pots may stand close to each other. We have just been putting in some good Rose cuttings in this way, bedding *Pelargoniums*, *Variiegated-leaved Geraniums*, and generally these turn out fine plants in the spring. We have also found *Anagallis* and *Verbenas* do well; but care must be taken that the latter have no thrips on them, so see they are all washed away. Even at this late period we would prefer such cuttings to securing old plants; but all who have old *Geraniums* that are pats, had better adopt some of the plans proposed by Mr. Beaton last week.

In the case of *Calceolarias* we have been a little nonplussed, as we like to strike them cool on a porous bottom. Well, the only place we could command, was some six lights of a brick-pit, emptied of boxes of *Geraniums*, just making roots nicely, and which were at such a distance from the glass as never to need shading. But the very depth was against our *Calceolarias*, which we did not wish to be more than 15 inches from the glass. So, we took some littery dung that had been thrown together until it had caked and heated itself white, and was not, therefore, likely to heat again, unless some damp and water was getting to it, which it was not likely to do except slowly during the winter. We put, therefore, about 15 inches of this litter in the bottom of the pit, well shaken, and well trod. Then above that 3 inches of rough leaf mould, well trod again, and then a sprinkling all over with lime, which was incorporated with the leaf mould to destroy any worms. Then 2 inches of sweet brown loam, and all well trod again. Then 2½ inches of loam and sand well mixed and sifted together, and a sprinkling of sand on the top, and all well beat level with the back of the spade. Here we will commence to-morrow to fill these six lights, and shall most likely find more room afterwards, using the short, stubby side shoots as cuttings about 1½ inch to 2 inches long, and from these we will remove a good portion of leaves, leaving the points and the buds on the sides, and inserting them in rows a little more than 1 inch apart, and 2 inches from row to row. They they will remain until planted out thinner under calico in March. *Ampelxianis* we will place in pots, and try to get where fire heat can be used, by November, as it is so much more tender than the rest. By a similar plan last season we hardly lost one per cent.—R. F.

TRADE LISTS RECEIVED.

A Catalogue of Plants Cultivated by George Jackman & Son, Woking, is an excellent general catalogue; and to the Fruit Trees and Roses are appended useful descriptive notes.

William Chater's List of Superb Double Hollyhocks and Pansies, Suffron Walden, will be found useful to those who take an interest in these flowers.

Supplément au Catalogue de l'hiver 1860, des Pépinières André Leroy, à Angers, consists principally of Ornamental Trees and Conifers.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E. C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

ALTERING FLOWER GARDEN (*Young Gardener*).—We never give plans, we only criticise those proposed. Cut down your Sea-kale just before you wish to commence forcing it.

HYACINTHS AND TULIPS IN SAND (*M. C.*).—You must add water as often as the sand appears dryish, but not otherwise. Late-flowering Tulips could be grown in the same way.

MUSCAT GRAPES SHRIVELLED (*A Subscriber*).—The shrivelling, in all probability, arises from the roots being too cold in proportion to the temperature in which the Grapes are growing. If the roots are outside, cover the border every night, but uncover it during sunny days. We should remove the soil until we came to the first roots, and then return over these not more than 6 inches deep of fresh, rich, light, warm soil; covering and uncovering as we have said. If the roots have descended deep, or are in a wet or heavy subsoil, they should be lifted to nearer the surface in the mode we have often directed.

WINTERING SCARLET GERANIUMS (*Rector*).—You will have seen full directions in our pages last week. Buckwheat, or Brank, should be sown in May.

INDIAN CORN (*A Devonshire Ticker*).—In your climate Indian Corn would probably ripen annually; but in less temperate districts of England it has been proved to be too uncertain a crop. It requires a very long and hot summer there to ripen. It is propagated by setting the seed in equidistant rows, from 2 to 3 feet apart. The proper season for planting it is from the middle of April to the beginning of May. For this purpose the earth is opened with a hoe to the depth of 3 inches or 4 inches, and in each hole are deposited four or five grains at a little distance from each other. As soon as the young plants appear, the weeds are carefully eradicated, and the earth gradually heaped around them, till the ears appear; after which they are left till the harvest arrives. The ears are then gathered and dried in an open situation; or if this corn be heaped together, it is apt to ferment and putrefy, or to sprout and grow. The best method of preserving it is to husk, or to thrash it out, as soon as the harvest is completed, to dry it perfectly in the sun, and deposit it in cool, dry, and airy situations. Maize, in countries where it is extensively grown, is subservient to a variety of purposes: is bulky stalks afford an excellent winter food for cattle, provided they have not been eaten in too dry a state. The American Indians parch the corn, and stuff it over a fire, without burning it, after which they pound it, mix the meal, and preserve the latter for their constant provision. In the United States excellent bread is prepared from Indian Corn by kneading the boiled flour into a stiff paste, either alone or mixed with that of rye or wheat, which is fermented with leaven or yeast, and then regularly baked. This bread is called Johnny-cake. It is sometimes made from the porridge of ground Maize, called homony, and is extremely palatable and nutritive. The America also converted the Maize into a species of malt, from which, as well as from the bread itself, they brew a wholesome beverage. The many purposes to which this grain may be applied, will be found well set forth in Cobbett's work.

REMOVING JASMINE NUDIFLORUM (*Rector*).—October and November would be a good time to remove *Jasminum nudiflorum*; but as that is its natural time of flowering it should not be removed then, except in a case of necessity. The end of February is the next best time to remove it.

BARENTON BEAUTY GERANIUM (*J. M. B.*).—Cotton wadding is the very worst thing to pack flowers in. We could not disentangle the flowers, or see what your seedling is likely to be. The petals were mashed into the wadding.

WORK ON SOLE (*A Constant Reader*).—Morton's "On Soles" will suit your requirements.

SEEDLING CARNACTIONS (*G. H.*).—Damp is the great enemy of Carnations. Pot off your seedlings into single pots about 3 inches across; keep them in a cold frame, and cover up when frost makes its appearance. In spring, plant them out, or better still grow them in pots. The soil to winter in had better be nearly all loam. Drain the pots well.

DAVILLA TERRENS (*A Young Amateur*).—The circumstance you mention would make no difference whatever.

GROUND VISBET (*F. G. S.*).—This useful structure, described at page 30, is 30 inches wide at the bottom, and 15 inches high from the ground to the top of the roof.

MELONS (*A Young Melon Grower*).—None will suit you for exhibition in June, July, and September, and to be grown on a dun-bed, so well as either the Beechwood, or Trenton Hybrid.

CATALOGUE OF STOCK PLANTS (*J. Finden*).—Write to some of the leading nurserymen; they will send you a catalogue gratis. We do not publish such.

CROCIUS-GLASSES (*Edith*).—None but the finest bulbs of Crocuses should be employed for growing in water, and such bulbs we have never found so small for the cup of those glasses. However, if you determine to use small bulbs, though it would be cheaper to buy finer, you may have small circular plates of zinc cut at any druggist's, just to fit the cups of the glasses, and have a small hole cut out of the centre of each zinc plate.

TENANT REMOVING GREENHOUSE (*W. P. T.*).—Have a wall-plate fixed to the leads on the roof of your house, and then fix the greenhouse to that with screws, you may then uncover and cover it at any time, and use the wall-plate. If we can we tell you how to stock a greenhouse in London without knowing what kind of plants you prefer; when you wish them to bloom; what its size is; or whether it is heatable in winter?

SOIL FOR CAMELLIAS AND AZALEAS (*An Old Subscriber*).—The sample enclosed to us is of the right sort, and should be mixed with a little leaf mould.

VERBENA AND PANSY SEEDLINGS (*G. Boothby*).—The Verberna was so valuable that nothing can be said about it. The Pansies are inferior to many varieties of the same class now in cultivation; and very much so to some of the newer ones coming out this season.

RAINFALL (*C. Fullbrook*).—The meteorological calendar is quite correct. The agreements are recorded as we have printed them.

WINTERING YOUNG PLANTS—STAGES—CELERY (*J. Wilson*).—We have no doubt the STOVES will answer the desired purpose. It will be as well to have them flat on the top to receive a vessel of water. In such a glazed house, if the plants are covered for a snow storm, you may pick off a six-inch deep round the front and end, and back again below the tiles of the floor if they could be raised without trouble, and that would disperse with all the both of the stoves. The floor of the house will hold a great many pots without a stage. However, you might fill the stage, and a good portion of the floor with straw. There is no reason why the Celery now but picking off the attacked leaves and burning them. When such an attack is dreaded a little lime and soot thrown over the plants will prevent the fly depositing the eggs. Nothing will reach the grub that is securely defended by the two skins of the leaves whilst he feels away inside. We have a little of it, and have not been troubled previously for twenty years, and hence our carelessness in not preventing the eggs being deposited. We should have expected myriads of caterpillars on our Cabbages if we had not sent a boy to beat down the butterflies.

BEDS UNDER TREES (*A Novice, &c.*).—The bare space under your group of Cedars would make the best and earliest flower-bed in the spring if you planted it with Winter Aconite, Snowdrops, and a succession crop of Crocus, to come in February, and go off in April; and the mice must be trapped. In April sow the space with common hay seeds from the stable-loom, and some of the grasses will be sure to do.

COARSE GRASS ON LAWS (*H.*).—The grass on your lawn is not one-half so coarse as that on the turf with which the new garden of the Horticultural Society was fenced; but by sowing plenty of white Clover seeds in February, you will get rid of the coarse grass, and the mowing you may, in two or three seasons, have a lawn soft as Enson down. Coarse lawns require to be very closely mowed once a week all the summer, and as late and as early as the blades can get a bite at it; that is the only secret.

VARIOUS (*A Novice and Old Subscriber*).—Nothing whatever could be made of the flowers and leaves; they were as much dried up as if they had been in it for weeks. If not securely shut, any neighbouring gardener or nurseryman would not hesitate to give you the information. The mode of sending such things to us has often been mentioned. In such circumstances the best mode to heat such a house would be by a small iron stove, with the funnel passing through a square of your glass window. In winter the rest of the square might be iron, with the hole left for the size of the funnel; you could remove that in summer, and substitute the glass square if they thought proper. In a fine season the Chasselas de Fontainebleau, in other words the Royal Mascadine, will bear and ripen on a west wall; but it would do better on a south wall. Plans for well-springs, &c. Reine Claude de la Vay, Jefferson's, Coe's Golden Drop. For bushes—Greengage, Orleans, Victoria, Washington. The New Hawthornden is a fine Apple for jelly. The Kilbston is much esteemed for preserves.

MANY QUESTIONS ABOUT GERANIUMS (*E. Mahy*).—Apologies will never excuse too many questions in one letter. I, some plants do and some do not show signs of being crossed in the seedling state. You did not say what plants you were sown with—Fuchsias for well-springs, Reine Claude de la Vay, Jefferson's, Coe's Golden Drop. For bushes—Greengage, Orleans, Victoria, Washington. The New Hawthornden is a fine Apple for jelly. The Kilbston is much esteemed for preserves.

FUCHSIA MANY-SEALED (*G. K.*).—We cannot tell why your Queen Elizabeth Fuchsia has so many sepals; but this transformation of stamens into petals and sepals is not uncommon.

STRAWBERRIES (*C. B. S. D.*).—If you cannot get the Strawberry under the name of Duchesse de Treviso, try for it as Vicomtesse Hericart de Thury. It is the same thing. Why do not nurserymen advertise these things? Nelson's Glory Apple must be the Nelson Codium; and Omar Pachá is not yet sufficiently known to have a reputation.

DISTANCE OF VINES FROM GLASS (*Nottinghamensis*).—About 1 foot is a good distance from the glass for the wires to be placed. We answer only one question out of five, as we must put an end to the practice of sending so many questions at once.

NAME OF GRAPE (*C. P. G.*).—It is a Black Hamburg, but the berries are small.

NAMES OF PLANTS (*H. B.*).—1, *Argemone mexicana*; 2, *Hydrangea quercifolia*; 3, *Clematis tubulosa*; 4, *Polygonum orientale album*. (*A Subscriber*)—1, *Asplenium bulbiferum*; 2, *Agathache cretensis*; 3, not sent; 4, *Linum grandiflorum*; 5, *Pilea sparganifolia*; 6, *Adiantum trapeziforme*; 7, *Sclagimella cressa*; 8, *Rhodnthe Maughlyana*; 9, *Portulaca*, no flowers; 10, *Portulaca*, no flowers; 11, *Portulaca officinalis*. It is a seaside plant. A pinch of fresh seed of it, if you have any, would be accepted by us with thanks. (*I. O. G.*)—1, very imperfect. An *Eryngium*, probably *oculeum*; 3, *Astragalus maxima*; 2, *Spiraea barbata*, sometimes called *japonica* in gardens.

FLOWER SHOWS FOR 1861.

- NOVEMBER 6th and 7th. ROYAL HORTICULTURAL SOCIETY. (Fruit and Chrysanthemum.) *Garden Superintendent*, G. Eyles.
- NOVEMBER 12th and 13th. STONE NEWINGTON CHRYSANTHEMUM SOCIETY. *Sec.*, W. T. HOWE.
- NOVEMBER 14th and 15th. CRYSTAL PALACE. (Chrysanthemum Show.) *Sec.*, W. HOUGHTON.
- N.B.—*Secretaries of Societies intending to advertise in our columns will oblige us by sending an early intimation of their exhibition days.*

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

JUDGING POULTRY.

It was not my intention to have trespassed again on your valuable space, but for the remarks which appear in your last Journal I trust you will grant me another portion of your columns.

The object I have in view in proposing a plan is, not to attack the honour or known integrity of our several respected poultry Judges; and under any plan however good, for my own part, I should be sorry to see them retire in favour of any young men, for more competent we are aware cannot be found, for their great experience must have given wisdom.

My idea is entirely for the benefit of the useful institution of poultry exhibitions. As far as they concern me, I have reason to be satisfied and have expressed myself to that effect before, and, therefore, consider myself not of the number of "riled or disappointed exhibitors."

It is my intention to show the necessity for amateurs, breeders, &c., to co-operate without expenses of any kind on the committees. This, I believe, I mentioned in my former letter, but which did not appear; also, they should even pay the ordinary charge to the exhibition for the benefit of the general funds.

In reply to Mr. Ballance's letter, I do not believe any of the exhibitors think of any incompetency of the present Judges, and, as a rule, believe, of course, the majority to be honestly and fairly judged; but, as it is clear from the letters published that there is dissatisfaction, not only in poultry judging but in judging Pigeons, Dogs, and Rabbits, it must be evident my desire is *pro bono publico*.

As regards the other letter in the same Journal, I feel rather astonished at the temper there shown by one who adopts the cognomen of "JUSTITIA."

I never heard a person consider poultry judging a sineure, however great the number of presents he may receive from breeders, &c.; but I have been told that it is frequently attended with much personal pleasure.

For the plain plan I propose, I desire nothing but what should be approved by all concerned. If "JUSTITIA" will assert that all are satisfied, I will send the names of some who have cause to contradict.

My motion is not an anonymous attack upon our respected Judges, as he says, my name and address being known to the Editors. To refresh the memories of your readers, the following appeared in your Journal:—

"Correspondent 'BANKER,' complains of the system of judging."
 "September 3rd.—Editors notice the imperfect judgment at the Crystal Palace, as well as the chance of falsity."

"September 17th.—Editors state 'it is understood, Mr. Challoner knows the marks of every breeder of Game fowls.' (Is not this the notion of unfairness?)

"September 24th.—Captain Hornby sees the necessity of more judges at shows generally. Exhibitors see the same."

"October 1st.—Editors notice the fallibility of judges at a rabbit show."

"October 1st.—'FIDELIS' complains of judgment, and Editors back the opinion."

With regard to my plan of the printed form for placing judgment, I cannot at present see the extra expense. Prepaid letters, and stamps enclosed for all reply, would more than pay for this printing.

There would be a little extra trouble to Secretaries in summing up the state of the poll, &c.; but for penning there could be no waste of time. If cards were printed with any two numbers, viz.:—(The Secretary under present plan registers the number he sends I presume.) Take down a register of the same, out the card through the centre; keep one for the exhibitor which he sends to him, the other for the show he keeps, register the cards thus:—No. 9 sent to exhibitor, No. 14 for the pen, or *vice versa*. When the basket comes with the fowls, &c., he turns to his register and finds No. 9 card is sent to the exhibitor, and is returned with the basket, and finds corresponding No. 14 is on the pen. This, surely, is not much trouble.

Emoluments I will not now dwell upon. Suffice it to say I think the Birmingham plan should, if there is anything like management, pay its judges (arbitrators only), secretary, and servants in a proper manner—in fact, I think the 21s. a shade too high, when one could only send a single pen. In conclusion, allow me again to impress upon all connected, or to whom my letters may apply, that my intention is not to be disrespectful in my writings; nor to thrust my notions down peoples' throats as infallible, being open to conviction if in error.—T. E.

WORCESTERSHIRE POULTRY AND PIGEON SHOW.—OCTOBER 8th, 9th, AND 10th.

There are, indeed, but few towns in the kingdom that possess so suitable a building for the purposes of holding a poultry exhibition as Worcester, the Corn Exchange being not only very roomy but one of the most equally-lighted buildings in which we have as yet seen a show of this description placed before the public. The Committee, too, are very ind-fatigable; and it is, therefore, a natural result that this Meeting is commonly admitted as being one of the most interesting to poultry breeders of any of our autumnal gatherings; a feature greatly strengthened by the fact that the successes gained at the Worcester Show are generally considered as affording a pretty conclusive idea of the relative strength of most of our principal poultry-yards in the fast approaching competitions of Bingley Hall and the Crystal Palace. For these particular reasons it is always regarded with both special interest and enthusiasm by those who wish to obtain the earliest information as to the probable competition at these our two largest poultry exhibitions. We will add no more than that the arrangements throughout did every credit to the Committee.

In the first-class, Black-breasted Red Game, the display was a good one; Mr. Horton, of Worcester, after a close competition, holding good the credit of the aloity with a very superior pen. The Hon. W. W. Vernon's birds are also well deserving of especial mention. In class 2, Brown-breasted Reds, Mr. J. B. Chune, of Coalbrookdale, took precedence with a capital pen; and one that, if we are not much mistaken, will show to even greater advantage when they become adult. Mr. Edwards, of Nantwich, was an exhibitor, who here ran in easily for the second prize. Mr. Corles, of Worcester, and Mr. Fletcher, of Manchester, stood very closely for the Duckwinged Game prizes. In the class for any other colour in Game fowls, Mr. Fletcher again took even a higher position with a pen of Blacks, Mr. Chune showing some excellent Red Pies for the second premium. In Spanish, Mr. Roddard took the premiums without any competition, but with capital birds. The Grey Dorking class was undoubtedly one of the most excellent in the Show. In this variety the Hon. W. Vernon exhibited a pen difficult to surpass anywhere, whilst the birds shown by H. Garrard, Esq., were but triflingly inferior; Mrs. Pettat's third-price birds were also very good. In the *Cochin* classes, the best represented of any variety was undoubtedly the Partridge-coloured ones; the White ones were also most commendable. The *Hamburghs* of all varieties were capital, except the Golden-pangled ones, of which breed only a single pen was entered, and that but barely good enough to take a second premium. All the winning pens of *Polands* were very superior—indeed, much better than commonly met with; two or more pens, however, were completely thrown out by the folly of their owners showing a humped-back bird. In every such case defeat is certain.

The *Geese*, and still more especially the *Turkey poults*, were first-rate.

In *Sebright Bantams*, this season, the Worcester Show has far exceeded any we have attended. Messrs. Leno, Bayly, Cruwys, Peters, Hodson, and Everett all showed capital pens; and, possibly, even yet the *Sebrights* may assume as important a position as they were accustomed to do in past years, when they were the most attractive feature to general visitors on account of their peculiar beauty of plumage and general character.

The weather was most auspicious, and the attendance highly respectable.

(From another Reporter.)

The "faithful city" always supplies a treat to amateurs, and the present Exhibition was no exception to the rule. The locality has been and remains celebrated in poultry annals. In the earliest days of the pursuit there were celebrated breeders of Game—Messrs. France and Hutton. Mrs. Herbert connected it with White Cochins; Mr. Archer first with Silver-pencilled *Hamburghs*, then with Game; Mr. Wakefield with Dorkings, and Col. Clowes with *Polands*. There are thus all the outlines of the classes on the spot, and faglemen of no mean order. They have not remained at home, but they are heard of at Birmingham, Liverpool, the Crystal Palace, and other places where the *elite* must do congregate. Worcester also possesses one thing, the want of which has hindered many shows and discouraged others. Some of us who saw the beginning of the movement can recollect the difficulties of the pioneers of it.

Lofts and yards were set round with pens; while the stalls of stables, where once coach horses were located, now received coverings of wire, and accepted pens of Turkeys and Geese as tenants. Nothing of the kind is necessary at Worcester. The Corn Exchange supplies all that can be wished for. It is roomy, lofty, light, and well ventilated.

We have seldom seen a prettier *comp d'all* than met us on entering the Exchange Tuesday last. Turner's pens were used, and the different shades visible to the eye, as if took in the five or six rows that filled the place, each surmounted by the varied hues of the Pigeons made a sort of miniature kaleidoscope. We noticed the condition of the birds left nothing to desire; and we did not observe one sickly one. This was a pleasing exception to some of the exhibitions we have had to report.

The lists opened with *Game*, a good and numerous entry of Black-breasted Reds, most of the celebrities being represented. Worcester held its own, and Mr. Horton was first, the Hon. W. Vernon second. The Brown-breasted Reds were not so good as their predecessors, and even the successful call for no especial mention. The Puckings and other varieties were not above the average. Exhibitors at this Show seemed to have expended all their energies in the first class. In the Variety class there were two pens disqualified by having crooked birds in them. *Dorkings* were a large and capital entry; many of our best yards were competitors, and the successful names will afford an insight into the merits of the class—the Hon. W. Vernon was the first, Mr. Garrard second, and Mrs. Pettat third. All the merits and properties that go to make up good Dorkings might be freely met with in this class, and we were glad to observe the birds were not fatted for competition.

There was but one class for this breed, and all, therefore, brought their best into it. If it can be considered an open list, where colour could pit itself against the other properties that go to make up a prize pen, colour had the worst of it. The Silver Greys did not get beyond high commendations.

Spanish were weak in numbers. Mr. Rodbard was the successful exhibitor.

Cochin-Chinas were all good classes in every respect. Miss Viola Musgrove had the honour of taking the first prize for Buff, followed by Mr. Bates, and achieving the proud distinction of defeating Messrs. Tomlinson and Cattell. Good, however, as the Buffs were, their Grouse and Partridge brethren were better, and the beautiful pen with which Miss Musgrove won at the Crystal Palace in August, and which was claimed by Mr. Tudman, here repeated for the third or fourth time since the purchase the exploit of easily distancing all competitors, gaining not only the first prize, but a beautiful china vase offered by Mr. Kerr, of the celebrated Porcelain Works, for the best pen of Cochins exhibited. The Whites also challenge our encomiums, and deserve them. We should grant them more readily if some of them were not so extravagantly value-hocked. We were delighted to see our old friend Mrs. Herbert first, but rather hard run by Mr. Chase.

Golden-pencilled *Hamburghs* were very good, and Messrs. Nuttall and Mann deserved their prizes, but they were not equal to the Silver. The first-prize pen of these birds was very beautiful, and those belonging to Messrs. Pierce and Griffith were also meritorious. We can say nothing in favour of the Golden-spangled that were shown, and the first prize was withheld; but the Silvers made amends, producing a class worthy of praise in every respect. Even Mrs. Pettat was obliged for once to be second, and to succumb to Lady Julia Cornwallis. She revenged herself by taking both the prizes for Golden *Polands*. Mr. Adkins seemed to have resumed the place he held years ago at the head of the Silvers. It was closely pressed by Colonel Clowes.

The "distinct varieties" were Brahmas, White Polands, Silkies, Andalusians, Black Polands, Ptarmigan, and cross-breeds. The *Turkeys* were excellent, and brought out a new exhibitor in Mr. Cattell. Had there been more prizes, Messrs. Crawshaw and Milward would have deserved them.

Mr. Fowler took all the prizes for *Geese* and *Aylesbury Ducks*. Mr. James Holme took both prizes for *Loons*. There was very good competition in the class for any other Ducks. Mr. H. D. Bayley deservedly won with beautiful Brown Calls, and Mr. Martin with Buenos Ayrean. These last were numerous, but exhibitors must bear in mind that with these birds large size is a fault.

We seldom recollect seeing a better show of *Bantams*. Every class was well represented. We may speak positively as regards

the Silver Scabrights, it is long since we have seen them so good or so numerous. Mr. H. D. Bayley won two first and one second prize for cock and two hens, and both the prizes for Single Cocks. Mr. Heath's Black-breasted; Mr. Camm's, Miss Musgrove's, and Mr. Leno's Silvers all deserve especial notice. The prizes for *Single Game Cocks* were taken by Messrs. Horton and Edward Archer.

Everything was well conducted, the birds were carefully tended and sent off, and Mr. John Holland was always at his post.

GAME (Black-breasted Reds).—First, H. Bolton, St. John's Worcester; Second, Hon. W. W. Vernon, Ranton Abbey, Stafford. Highly Commended, J. R. Rodbard, Aldwick Court, Wington, near Bristol. Commended, E. Archer, Malvern; G. S. Cruwys, Bridgwater Court, Somerset, Devon.

GAME (Brown-breasted Reds).—First, J. R. Chine, Colbrookdale, Second, S. Edwards, Leam Street, Old Red Cow, Nantwich, Cheshire. Commended, E. Archer, Malvern.

GAME (Puckings and other Greys and Blues).—First, W. Corles, the Grange, St. John's, Worcester. Second, J. Fletcher, Stone Clough, near Manchester. Commended, J. B. Chine, Colbrookdale.

GAME (any other variety).—First, J. Fletcher, Stone Clough, Manchester (Black). Second, J. B. Chine, Colbrookdale (Piles). Highly Commended, J. R. Chine (Hark); Corbett, Tallow Hill, Worcester.

DORKINGS (Coloured).—First, Hon. W. W. Vernon, Ranton Abbey, Stafford. Second, E. H. Gattard, Salford Vicarage, near Evesham. Third, Mrs. Pettat, Ash Rectory, Basingstoke, Hampshire. Highly Commended, Lady J. Cornwallis, Linton Park, Staplehurst; E. H. Garrard; Rev. F. J. Nelson, Kings of Cleveland, Stokesley, Yorkshire; H. W. B. Berwick, Helmsley, Yorkshire; W. Dolly, Stratton, Old Hall, Grantham. Commended, Lady J. Cornwallis; E. Tudman, Ash Grove, Witcheur, Salop.

SPANISH.—First and Second, J. R. Rodbard, Aldwick Court, Wington, near Bristol.

COCHIN-CHINA (Cinnamon and Buff).—First, Miss V. W. Musgrove, West Tower, Angthon, near Ormskirk. Second, H. Bates, Harbourne Heath Cottage, Edgbaston, Birmingham. Commended, H. Tomlinson, Balsall Heath Road, Birmingham; J. Cattell, Birmingham.

COCHIN-CHINA (Partridge and Grouse).—First, E. Tudman, Ash Grove, Witcheur, Salop; J. B. Chine, Colbrookdale, Worcester; J. B. Chine, Colbrookdale, Worcester. Highly Commended, Mrs. S. R. Herbert, Powick, near Worcester. Commended, P. Cartwright, Oswestry.

COCHIN-CHINA (any other variety).—First, Mrs. R. Herbert, Powick, near Worcester. Second, R. Chase, Moseley Road, Birmingham. Highly Commended, Mrs. E. R. Herbert. Commended, W. Davson, Hop-on Mirfield, Yorkshire; R. Chase.

HAMBURGERS (Golden-pencilled).—First, A. Nuttall, New Church, near Manchester. Second, J. Mann, Stacksteads, near Manchester.

HAMBURGERS (Silver-pencilled).—First, J. Martin, Mildenham Mill, Claines, Worcester. Second, W. Pierce, Harford, Northwich. Highly Commended, G. Griffiths, Church Street, Worcester.

HAMBURG (Golden-spangled).—Prize, S. Hyde, Taunton Hall, Ashton-under-Lyne.

HAMBURG (Silver-spangled).—First, Lady J. Cornwallis, Linton Park, Staplehurst. Second, Mrs. Pettat, Ash Rectory, Basingstoke. Highly Commended, P. Joshua, Perrot's Brook, near Cirencester; J. Fielding, New Church, near Manchester.

POLANDS (Golden).—First and Second, Mrs. Pettat, Ash Rectory, Basingstoke.

POLANDS (Silver).—First, G. C. Adkins, the Lightwolds, near Birmingham. Second, Lieut.-Col. Clowes, Frome Court, Crowle. Highly Commended, Mrs. Bly, the Poplars, Gregory's Bank, Worcester.

POLANDS (Black with White Crests).—Prize, T. P. Edwards, Lyndhurst, Hants.

ANY DISTINCT VARIETY NOT INCLUDED IN THE ABOVE CLASSES.—First, J. K. Fowler, Prebendal Farm, Aylesbury. Second, Lieut.-Col. Clowes, Frome Court, Crowle. Commended, Mrs. Bly, Worcester.

TURKEY POULTS.—First, J. Cattell, Birmingham. Second, Master E. Gray, Eaton, near Grantham. Highly Commended, Miss L. Crawshaw, Cuckoo Bank, Reading. Miss J. Milward, Newton St. Loe, near Bath.

GOSLINGS.—Prize, J. K. Fowler, Prebendal Farm, Aylesbury.

DECKLINGS (Aylesbury).—First and Second, J. K. Fowler, Prebendal Farm, Aylesbury.

DECKLINGS (Down).—First and Second, J. Holme, Knowsley, near Prescott. Highly Commended, J. K. Fowler, Prebendal Farm, Aylesbury; W. Joshua. **DECKLINGS (any other variety).—**First, T. H. D. Bayley, Ickwell House, Biggleswade, Beds. Second, J. Martin, Claines, Worcester. Highly Commended, Mrs. Beadmore, Uplands, near Farnham, Hants; W. Joshua.

BANTAMS (Gold and Silver-bred).—First, Mr. Leno, Jan. the Pheasantry, Markyate Street, Herts. Second, T. H. D. Bayley. Highly Commended, Rev. G. F. Holton, North Petherton, near Bridgwater, Somerset; G. C. Peters; G. S. Cruwys, Winton.

BANTAMS (Crows or White).—First, T. H. D. Bayley. Second, G. S. Cruwys. Highly Commended, G. Peters. Commended, E. Hutton, Pulsey, near Leeds.

SWEETSTAKES.

GAME COCK CLASS.—First, H. Horton, Worcester. Second, E. Archer, Malvern.

GAME BANTAM COCK.—First and Second, T. H. D. Bayley. Highly Commended, J. Orm.

PRIZES.—*Power's* (any colour).—Prize, H. Child, Jun. *Carriers*.—First, W. S. S. A. S. Sylvester, Birmingham. *Almond Tumblers*.—First, J. Percival, Bye Lane, Peckham. Second, G. C. Adkins, Lightwolds, near Birmingham. *Mottled or other Tumblers*.—Prize, J. Percival. Commended, F. Esquima, 346, Oxford Street London. *Balls or Hearts*.—Prize, F. Esquima, Commended, J. W. Edge, Birmingham; H. Morris, Forest Hill, Evesham. *Reds (Silver or Blue)*.—Prize, J. W. Edge. Commended, E. A. Hargrove, Handsworth, Birmingham. *Orbs* (any other colour).—Prize, J. Percival. Highly Commended, W. Squire, Hanwell, Middlesex.

Barbs (any colour).—First, E. A. Hargrove. Second, A. S. Sylvester. Commended, H. Morris. *Fantails* (White).—First, J. W. Ldgc. Commended, Mrs. J. Milward; G. C. Adkins. *Yons* (any colour).—First, withheld. Second, J. W. Ldgc. *Trampeters*.—Prize, J. Percival. *Turkies*.—First, G. C. Adkins. Second, F. B. Elze. Commended, J. Percival (very nice class). *Jacobins*.—First, F. Esquilant. Second, withheld. *Rouls*.—Prize, G. C. Adkins. *Anteprps*.—Prize, H. Taitley. *Any New or Deserving Variety*.—Prize, E. A. Hargrove.

Mr. John Bailey, of London, and Mr. Edward Hewitt, of Birmingham, were the Judges.

ABOUT EGGS.

An egg of the average size weighs 1000 grains, or one-seventh of a pound. Three-fourths of its weight are water. One-seventh is albumen, a highly nutritious substance, resembling lean meat in its composition, and, therefore, adapted to produce strength of muscles when consumed as food. One-tenth of the weight of the egg is fat or oil, which is useful to supply carbon for respiration, and heating the body, and, therefore, especially valuable for eating in hot or cold weather. The yolk contains some sulphur and phosphorus compounds, the latter affording material for the bones (and brain). The shell is chiefly carbonate of lime, similar in composition to marble or limestone. The shell is porous, and admits air for the chicken before it breaks out. Of the entire egg the shell weighs about one-tenth; the yolk, three-tenths; the white, or transparent portion, six-tenths. The composition of an egg is quite similar to that of a piece of good fat beefsteak with the bulk of the loose fat, or tallow, trimmed off: eggs are, therefore, nutritious food. Seven eggs, weighing a pound, are nearly as valuable for food as a pound of good meat, and they generally cost much less. During the past few months seven eggs have cost only 7 cents at retail in our market; while a pound of sirloin beef has cost 14 to 16 cents, and a good steak from the round, 12 to 14 cents per pound—being two to one in favour of eggs.

In cooking eggs most families boil or fry them hard. This renders them bad to digest, unless they are masticated very fine, and this is seldom done in rapid eating. They are every way better if soft boiled, and, after a little practice in eating them thus, a hard-boiled egg is comparatively dry and tasteless. An egg placed in boiling water just three minutes, or, if a large one, three minutes and a quarter to three minutes and a half, is abundantly cooked. After removing from the water, the eggs need to stand a few minutes to heat through to the centre. After becoming a little accustomed to them, eaten with the addition of a little salt and pepper, or other condiment, eggs thus cooked are palatable as butter, instead of requiring to be covered with butter.

PRESERVING EGGS.—As above stated the shells are porous, and the water of the egg is constantly evaporating, and air entering to take its place. After a time, decay commences. It will readily be seen that stopping the pores of the shell will tend to preserve the contents in their natural state. This may be done by dipping them quickly in melted tallow, or coating them with sweet oil, or a solution of gum, or varnish. Milk of lime—that is, fresh-slaked lime mixed with water to a milky consistency, fills up the pores pretty well. Thus coated, they need only to be placed in a cool place of uniform temperature. A pecking of chaff, bran, salt, ashes, charcoal, dry sawdust, or any similar porous material, preserves the uniformity of temperature by means of the nonconducting air confined in the spaces. Perhaps there is no simpler way of keeping eggs than to dip them in melted tallow, peck them in dry chaff, and store them in a cool, dry cellar.—(*American Agriculturist*.)

COMBAT BETWEEN A HEN AND AN ADDER.—The *Agr. Advertiser* notices a battle between a hen and an adder, near the village of Old Minninghoff. From the manner in which she jumped among the long grass on the bank we at first concluded that chuckie was tethered. Not so, however, for on making a sudden dart down, she suddenly lifted and threw about a yard high, what at first sight appeared to be a worm of 10 inches or 12 inches in length. This she continued to do half a dozen times in succession with the utmost rapidity, until it finally fell over the bank, when we at once perceived the reptile of chuckie's attention was no other than an adder. Having gazed a moment over the bank after it fell, she turned round about and uttered a few victorious chuckings, when to our further astonishment, there appeared first one tiny head and long neck, and then another

and another above the grass, until a whole brood of chickens appeared and clustered around her, of whose existence we were not aware during the combat; but, doubtless it was for their protection that chuckie had engaged in so dangerous a duel.

A BROOD OF DRAKES.

ABOUT five months ago I purchased a sitting of eggs from prize Aylesbury Ducks. Seven hatched to my great delight, thinking, of course, I had got a breed of them at last. I took every possible care of them, giving them all kinds of nutritious food to make them very fine ones, which I have pleasure in saying they are. But what do you think I have for my trouble, not to say my expense? I have the pleasure, after five months' careful attention, of finding that they are every one *drakes!* Now, is it possible by examining eggs to foretell the gender of the young one? I feel very much inclined to believe it is. Perhaps it is an omen of something very bad going to happen to me, as a friend of mine told me it was a sign that I should die a bachelor. I killed off all my old stock to make room for these eight pure-bred gentlemen, which now constitute the whole of my stock for next year's breeding.—**DRAKE.**

[There is no mode of foretelling the sex of the future product of an egg; nor do we think a brood of drakes prophetic of bachelorship; at all events we know a gentleman who had a brood all Ducks, yet he has no chance of having more than one wife. Keep one of your drakes, and buy three pure Aylesbury Ducks to form his harem. The progeny will be finer than if you bred from Ducks of the same brood.]

THE QUEEN BEE.

DOES A VIRGIN QUEEN BREED DRONES.

LIEUT.-COL. NEWMAN may well hesitate at receiving the doctrine of true parthenogenesis in the honey bee, which, as I have before stated, is a phenomenon of so extraordinary a character as to require the most conclusive evidence before it can be recognised as an undoubted fact. At the same time, I am quite at a loss to perceive what argument he seeks to draw from analogy with the natural history of humble bees. Although circumstances have occurred in my own apiary which, when taken in conjunction with the testimony of others, leave no doubt in my mind they are, as I have already stated, so far short of absolute proof as scarcely to be admissible as arguments. I can, therefore, only refer the gallant Colonel to the evidence of Siebold, Dzierzon, Berlepsch, and Langstroth, recommending him at the same time to satisfy himself by actual experiment of the truth or falsehood of the modern theory.

The present is a very able period for repeating the experiment of Berlepsch by rearing a few queens at a season when no drones exist to fecundate them. Assurance might at the same time be rendered doubly sure by clipping their wings as soon as they issue from their cells. If under these conditions the young queens turn out drone-breeders in the spring, I fancy Colonel Newman will have little reason for further doubt.

I beg to assure your respected correspondent that I am a very ardent admirer of the immortal Huber, and esteem his work as a most wonderful and valuable production. At the same time, I am far from believing that it has by any means exhausted the subject on which it treats, and feel assured that its illustrious author, if now living, would rejoice to find it a stepping-stone to further discoveries in that science, which he has done so much to advance.

I happen, also to be well acquainted with Mr. Huish's book, and rate both it and its author at their true value. Whilst thanking Col. Newman for his advice to peruse it, will he excuse my hinting a suspicion that a slight spice of irony lurks under that strong recommendation? I may be permitted to ask if he can point out any one passage of my writing which warrants his insinuation that I have anything to learn from a source so utterly contemptible? and in my turn recommend him by no means to retrograde fifty years, but attentively to peruse the modern and trustworthy authorities whose names I have already mentioned.

In conclusion, I venture with all due deference to the gallant Colonel to controvert one of his very positive but decidedly incorrect assertions. I have repeatedly proved that the absence of confusion on the discovery of the loss of a queen by no means

demonstrates the existence of either royal embryos or young queens within the hive at the time.—A DEVONSHIRE BEE-KEEPER.

P.S.—I fancy Colonel Newman will be disappointed in the hope he professes to entertain of soon perusing detailed particulars of the quality and quantity of honey taken from flourishing Ligurian stocks. I have already given the results of my own experience, which I consider most favourable; and Messrs. Neighbour can show him two boxes of honey collected by my Ligurians which may well satisfy him in respect of quality. But I imagine the fortunate possessors of strong Italian stocks will have been, like myself, far more anxious to propagate the species as rapidly as possible, than to test for the present their honey-producing qualities.

VENTILATING OBSERVATORY-HIVES.

To assist your correspondent, "A. W.," in getting rid of the condensation in his observatory-hive, complained of at page 472 of the last volume, I may be permitted to describe the plan I hit upon when similarly situated. He informed us previously of having rendered his hives complete by adopting the Woodbury-bar, further improved by grooves being run in its sides to work slides; thus dispensing with the clumsy crown-board.

Assuming his observatory so provided, by cutting up fine India matting into strips, the same length and breadth as the slides, one end tacked to the under side of a little end bit of slide—say 1½ inch long, the other being run into the grooves, after the wooden slide has been withdrawn, acts as a handle to work with.

On adopting this simple device he will find the ventilation more in keeping with the perfection attained in straw hives, and the prosperity of his Ligurians materially promoted.

I previously alluded to this at page 90, but from a typographical error my meaning was somewhat obscured.—A RENFREWSHIRE BEE-KEEPER.

YOUNG BEES EXPELLED FROM HIVES.

I HAVE to thank you for your editorial remarks, as well as Mr. Fox, and "A NORTH STAFFORDSHIRE BEE-KEEPER," for their kindly co-operation in endeavouring to solve the enigmas of the expelled bees.

So far as my comparatively limited experience went, such a proceeding was quite inexplicable. I recollect the end of May was a twelvemonth of a good hive throwing out half-formed drone-brood. I was puzzled at first, but on feeding liberally that difficulty was removed. I also witnessed well on in July of this year, a couple of stocks that long hung out threatening swarming, cast forth large quantities of similar drone-brood. This, however, I looked upon as the signal they had determined not to swarm, and that this measure was an exemplification of their usual wonderful foresight; but when my best-stored hive, after throwing a couple of swarms, too, commenced the wholesale expulsion of living worker bees, their very desideratum, I must confess I was as much nonplussed to account for the phenomenon as ehagrined at it; and with all the light that has subsequently been thrown upon the subject, I fear I must own I am yet in the dark. This colony has expelled as many young bees as would form a small swarm. The case of last season and the other two this were hardly worth mentioning in comparison. The evil by degrees slackened till a fortnight since it totally terminated. I am, therefore, now unable to satisfy Mr. Fox as to the imperfection of the wings, but my own impression at the time was, the wings were as far advanced in proportion as the rest of their bodies. Their not attempting to fly I felt disposed to ascribe more to general debility than to any particular shortcoming in these organs—in a word that they had issued prematurely. That good apianian is perfectly correct as to external heat having nothing to do with the mischief. We had, as he remarks, but a low temperature this summer besides little sunshine, and in addition, this particular hive was well shaded by a thick straw thatch.

The only satisfactory conclusion I have come to is, the long continuance of uncongenial weather was the cause; but how it operated to produce the effect I am still at a loss to conceive, unless I fall back on my original surmise, that the bees being imprisoned within the hive from the above cause, although they

had plenty of honey, were unable to carry in pollen in anything like the quantity requisite to keep pace with the rapid breeding of a vigorous young queen; and, consequently, from a deficiency of this most essential condiment in the early age, lacked constitutional stamina, and emerged in an enfeebled condition, or owing to the same bad weather the whole inmates through confinement were converted into involuntary nurses on the brood, and by the high temperature thereon the youngsters issued prematurely.

I cannot coincide with the supposition that the bees are in any way diseased (the other two hives are in no way related). On the contrary, the existing adult population are numerous and very vigorous; indeed, ever since their establishment last season (a couple of weak colonies in Stewarton-boxes then joined), they have displayed an irascibility and blood-thirstiness extending to all and sundry, as well as their own offspring, I have never seen equalled, no one daring to pass within a yard or two without molestation. Indeed I scrawled these lines under the disadvantage of having one eye about closed—the effect of a sortie when recently passing their octagon stronghold.

It may be proper to mention, I ascribe the cause to the long continuance of bad weather, from witnessing the same peculiarity during such weather last season as well as this. The other two hives also proving it was not attributable to anything individually defective in the worst, but only its greater extent, resulting from superior strength in population and store, exerting their wonted stimulating effects on a vigorous young queen. I have also heard of a similar bad case with a neighbour. The ultimate fate of his hive as well as my own shall be duly reported by—
A PERPLEXED YOUNG BEE-KEEPER.

DRONE PRODUCTION BY OLD QUEENS.

CONFIRMATORY of what "A DEVONSHIRE BEE-KEEPER" remarks at page 492 in your last volume, on old queens returning to the drone-laying condition of virgins, I may remark, the first colony of bees I possessed was a prime swarm in a common straw hive, consequently a queen of the previous year at least. Although the hive was weighty, for the three following good seasons it stood, anxiously expected and carefully watched, but gave no swarm. I recollect, my hopes were greatly buoyed up by its strength in drones, which each season increased till the last, when they exceeded all due proportion; so, being thoroughly sickened, I fumigated the hive, caught and killed the venerable lady, adding her subjects to another colony.—A RENFREWSHIRE BEE-KEEPER.

HOW I BECAME AN OXFORDSHIRE BEE-KEEPER.

(Continued from page 432.)

Now for the details of my present swarming season, and towards a quicker comprehension of my ways and means, I will tally my hives, so that my readers may follow their offspring without any very great tax upon their memories. I will specify my four hives as age 6, age 3, age 2, age 1, each figure corresponding to its length of years respectively. Should I go from home in the swarming season, I take care to leave every requisite that may be wanted for that end in proper order, and to intimate to my friend and pupil (in bee-keeping) how I wish swarms so-and-so to be placed, premising so and so should happen. And it happened this year that I was very delightfully occupied in the new gardens of the Royal Horticultural Society at Kensington store, on the 5th of June, the day of their opening, when age 3 and age 2 gave me two "prime swarms." Age 3 issued first, and settled on a row of peas (Sungster's No. 1.) Age 2 then followed suit, and flew and joined them, which saved Mr. Morris that operation in the evening. 12th, a cast issued from age 3, and one also from age 2; they also settled in the peas, from whence I lived them, and they apparently took to their new quarters comfortably, though both casts harked back again to their parental homes within the period of two hours. When I was a watchmaker and working-jeweller in Knightsbridge, years ago, I well remember a tall man, with a stentorian voice, who cried his "shrimps as large as prawns;" but my casts really are as large as common swarms. Loud trumpeting in the above hives in the evening.

June 13th, a swarm issued from age 1, and settled in the peas.

The two casts of the previous day also issued again: the one from age 3 settled in the pens, and the other seemed bent upon a neighbour's garden; but I appeared in the nick of time to bail them with "Boys, boys, b-o-o-o-o-y-s!" when they returned and settled in a gooseberry bush. After living the cast from age 3, took a fancy to fly and unite themselves to the cast from age 2, which was exactly what I wanted them to do, and I felt much obliged. At halfpast nine P.M., I placed the swarm in its new station, and joined the two casts to it; and the bees had all amicably assembled the hive by eleven o'clock, so I placed them at once upon their stand, which relieved me from the necessity of arising by daybreak the next morning to do so.

My method of uniting bees is as follows:—A few hours previously, and from the hive which I intend to add to its numbers, I take off the pan and disconnect the propolis from the board by forcing the hive a little out of the position which it occupies. Then, just at the dusk of evening, I spread a cloth by its side upon the walk, and at about a foot apart, extend two three-quarters-of-an-inch-square sticks, about 2 feet long, upon it. Then carefully bring the hive with the new swarm, or cast, quietly set it upon the sticks, and strike it on the crown rather smartly with a moderate-sized shillah; then catch up the hive, instantly, and clapper it quickly three or four times between one's hands, and the concussions will project every bee upon the cloth. Then, expeditiously, and with main strength, place the hive from the stand over them, when the sticks will prevent it from crushing the bees. Wait what bees remain upon the bee-board with the wing on to the cloth, bring the four corners of the latter on to the top of the hive, and secure them there with a piece of brick, or a stone; and presently, the upgar will prove tremendous. Place the pan over the bee-board on the stand, and in an hour or so's time spread out the corners of the cloth again, when, should the bees have all ascended the hive, it may be placed on its stand at once, though it rarely happens that they will have achieved so much when they are united to a hive which has been previously long occupied and stored: therefore, arise and adjust it in the morning, just at the break of day.

In early summer mitings few dead bees will have to be deplored, in autumn joins with old bees a more fatal battle field may be the result, though I have never had a case to cause me much affliction through paucity of conscience in that respect; but then I allow the new subjects to gorge themselves to repletion before I enforce the encounter, of which more anon. A dead queen is sure to be the result; and in the event of uniting a cast in summer, sometimes two or three, and three times during my experience. As regards the latter, instead of bringing the cast to the stock, I have been obliged to take the stock to the cast—for this reason: frequently a plural number of queens will issue with a cast, and when that happens latish in the day, there will not be time sufficient allowed for them to settle their little differences, as to which is to retain possession of the Nyanjan belt. There will be one queen, perimps, with a complement of subjects congregated outside the hive, another inside, and another on the surface of the cloth. In those transactions the plan is to bring the stock-hive on its board to the spot, and the divided community on to the cloth, shillah-like, and place the stock-hive on the bricks over them, and there will soon be heard trumpeting sufficient to compete with half-a-dozen children at a fair. Early in the morning place the hive upon its board upon the spot, and bear it off to its stand with its new colonial increase. An extended battle-field will be found to be the result on these occasions amongst the communally, more or less, and I have by me now three dead queens which met with their death last year in an encounter, similar, amongst numerous dead subjects. I have had no fighting at all amongst the uniting workers this season at present, neither have I experienced one wet night whilst performing the amalgamations. Last year I was very unfortunate in this respect; but I thought me to take the wheelbarrow, with the cloth spread over it, to dash the bees on to it, place the stock-hive off from it, with part of an old door over all to cast the wet slanting off from it, and I found the plan answer well.—UPWARDS AND ONWARDS.

(To be continued.)

THE BEE SEASON IN ROXBURGHSHIRE.

The bringing from the heather is just over, and a very great inequality of weight is noticeable among hives that have been located even on the same moorlands. The season, as a

whole, has been a bad one for bees. They had only a fair beginning in the making of flower-honey when the rain commenced, which sealed over the honey-producing flowers. Bees generally begin to lay up flower-honey about the middle of June, and at the beginning of July the weather broke up, and it continued wet, more or less, until the best of the bee season was past. Many hives recruited much on the heather, which this year has been in fine bloom on the border moorlands. The honey is scarcely so fine as in years when flowers are less rain-closed and bee-proof. The honey yield is also much below an average in quantity. Some splendid hives have been brought home, and many miserable ones. The heaviest we have any knowledge of weighed 58 lbs. and some of the accompanying hives to this weighed so low as 8 lbs. and 10 lbs. Many hives are from 15 lbs. to 25 lbs. A hive, it is considered among "bee-men," can winter if 30 lbs. in weight, but those below that require food. The number of bee-keepers on the borders is great, and many of them have from ten to thirty skeps. We know some with even more. No hobby seems to take firmer root than that of bee-keeping, and it is a hobby that gives daily anxiety or pleasure, and one that occasionally leaves a sting behind. Whole hives of bees, by the way, found their way into some shops in the towns. We know a draper's shop into which two hives came, they having apparently lost their queen. The extra number of bees about shops in general this year plainly shows that the season has been a poor one for them.—(Scottish Farmer.)

SONG OF THE BEE.

BY HANSAL F. GOULD.

We watch for the light of the moon to break
And o'er the eastern sky
With its blended hues of sapphire and lake,
Then say to each other, "Awake! Awake!
For our winter's honey is all to make,
And our winter bread for a long supply."

And off we lie to the hill and the dell,
To the field, to the meadow, and lower;
We love in the columbine's horn to dwell,
To dip in the lily with snow-white bell,
To search the baln in its odorous cell,
The mint and the rosemary flower.

We seek the bloom of the eglantine,
Of the painted thistle, and the poppy,
And follow the steps of the wandering vine,
Whether it trail on the earth supine,
Or round the aspiring trellis twine,
And reach for a state still higher.

While each, on the good of her sisters bent,
Is busy and cares for all;
We hope for an evening with hearts content,
For the winter of life without lament,
That summer is gone, its hours mispent,
And the harvest of life is past recall.

—(Prairie Farmer.)

OUR LETTER BOX.

MORE DEATHS OF BIRDS SHOWN AT SHEFFIELD.—J. H. K. exhibited Game fowls, ducks, and chickens. A day or two after their return all the chickens died, and one hen.

SUPPLY OF EGGS (F. A. C.).—Six Cochon-China pullets for winter supply, and six Hamburgs for summer, will keep you well supplied.

CLAWS OF DOVEKIN COCKLEBILLS (F. A. C.).—The comb nail on the claw of the forehead will not develop into a horn with the claw placed in contact with the skin, unless it be so placed as to appear a deformity.

POULETS UNABLE TO STAND (All Society).—Your birds from your description are all changed. If the floor of their roosts be brick or stone, that will in some measure account for it. Put the birds on straw or dry gravel; keep them warm, and well fed on meal and stimulating food, but no rice or white corn.

ATLE-BURY DUCKS' PILLS (Constant Subscriber).—As their bills are too yellow, let them have grit and chalk in their water. Keep them carefully in all ponds of discoloured water, or water with iron in it. Let the Ducks out in meadows when cold dew or white frost is in the grass.

WHOLE-FEATHERED TUMBLER PIGEONS (Philo).—You might enter the pair of whole-feathered Tumblers in the class for "any other variety" at Birmingham. They are clearly not eligible for either of the Tumbler classes, as they are not Amadons and Mottled. There would be no chance of their being disqualified in the "variety" class.

PIGEON'S EYES INFLAMED (F. Hussey).—It is almost impossible to tell the cause of the disease in the eyes of your correspondent's Pigeon. Possibly it may be simply a cold or inflammation, in which case give tonics, and bath the eyes with a cooling lotion, or if it is a chancre, that the bird is suffering from roup, and the nostrils have become clogged, so that the discharge passes out of the eyes, and consequently inflames them. If such is the case give Smith's forge water, or sulphate of iron in its drink; feed on good wholesome food; endeavor to clear the nostrils and remove the obstruction, and bath the eyes with weak gualter or cherry-flower water. A purge of two of butter, fresh air, and a run in the garden, may greatly improve the bird's general health.—B. P. B.

WORK OF CASARIES (J. Phillips).—There is no such work yet published; but very shortly we shall produce one prepared by Mr. Brent.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 36.57 and 39.4 respectively. The greatest heat, 73°, occurred on the 21st in 1850; and the lowest cold, 17°, on the 23rd in 1859. During the period 121 days were fine, and on 117 rain fell.

THE BEDDING-OUT AND MIXED BORDER SYSTEMS.

SAy what you will in favour of mixed herbaceous borders, popular opinion, I was almost going to say prejudice, runs high in favour of the bedding-out system. Do not be alarmed, you who enter for multitudinous variety, for I applaud your exertions and enthusiasm, although not a convert to your notions. It is

true you have the pleasure of seeing something new in your morning walk all the year round, which the most fastidious opponent to your way of thinking would be obliged to concede was beautiful, interesting, or rare, as the case might be, individually; but collectively the best-arranged herbaceous border seems always clad in half mourning.

"This is all very well this bedding-out system," says an eloquent friend, "grand masses of bloom, a fine field for displaying artistic arrangement; but don't tell me there is this difficulty and that difficulty in mastering that part of your business, for you only want to know the names of about a dozen plants and have plenty of them."

Be this as it may, the bedding-out system is notoriously fashionable, and is more and more fostered every year. The ladies descendant upon its beauties, pay a tribute of admiration to a well-arranged parterre, and are ever ready to suggest other colours to harmonise, or other colours to contrast with one another in the various combinations of "ribands," "panels," &c. There is certainly a great increase of labour during the propagating and planting-out seasons too often with scanty appliances, in any point of view you may choose to look upon it; but if it can be done at all, if done well all the better, it is "worth all the money." Depend upon it, once bring it before the tastes of the wealthy and the affluent—there may be, and always are, exceptions; to speak mildly, they will go a certain way to second your requirements. They are compelled to argue it in this way: "We must keep up with the spirit of the age. It is fashionable this massing system, and our friends who have seen our gardens this season, and who have been loud in their praises, would question very much our tastes, if, for the sake of a few pounds annually (and it is not so very much more after all), we were to allow our gardener to retrograde from, rather than to advance with, the style which we all so much admire."

From this hypothesis we may expect that the modern style of gardening is decidedly popular; and not only so, but we expect to see first-class gardening set down for

what it is really worth; for it has been, we would with all deference suggest, the habit of late years for the middle classes, more especially the urban populations, who are not so frequently associated with gardeners and gardening, to look upon the profession and the members of it as little better than unskilled labourers; ergo, day labourers carry on the work. The scales are gradually loosening from their eyes in proportion as they are privileged to see the various subjects with which the gardener has to deal, and they occasionally jostle against a coterie of the profession who are scarcely less intelligent than they. To all gentlemen who may be inclined to combat the point with me, we say, Go and see for yourselves, and take a lesson from the sensible reply of the Prince Consort at the opening of the Kensington Gardens, where you will find he elevates gardening to a science. Let young gardeners look at this and be stimulated to extra exertions, both in a practical and theoretical point of view; and if they do their duty, the high claim represented by a very high authority will be quite safe in their keeping.

Now, I can imagine a great many disclaimers among your readers as to the wisdom, in their case, of such sweeping laudations in favour of the bedding-out system. I am perfectly aware that the enthusiastic inmates of the cottage, and even a great many of the villa gardens, must have their Phloxes, Pentstemons, Antirrhinums, Dahlias, Hollyhocks, Roses, &c., arranged together in a border, because they have neither means nor space to devote to them in any other manner. We beg to assure them that they are not included among those we would rally round our standard. It is as pleasant for any of us to see their exertion successful in a small way, as it must be to them to feel that their labour has not been spent in vain.

There is quite a revolution in Scotland during these last ten years in the management of the cottage and villa gardens; and so great an advancement is mainly attributable to the local flower shows held almost in all villages of any note. At one or two of these local exhibitions we may state there were much finer spikes of Phloxes and Pentstemons grown and exhibited by the cottager than those exhibited by those gardeners that came forward both at Edinburgh and Glasgow. It is certainly surprising to see the tastes of those humble men and women as displayed in their mixed arrangement before the fronts of their dwellings. But that is not all, I happened to be one among others who awarded a first-class extra prize to an indefatigable cottager who had kept over, without any neutral assistance, Scarlet Geranium Tom Thumb for the last twelve years, and exhibited it this autumn 5 feet across, full of bloom. This shows what can be done with a thermometer, as was the case last December, indicating 11° below zero. Once organised a spirit of rivalry in a district, and you will find the adage true to the letter, "Necessity is the mother of invention." As it is with the peasant, so it is with the peer. Let us show what can be done, and the rest will follow.—JAS. ANDERSON, Meadow Bank, Uddingstone.

A FEW DAYS IN IRELAND.—No. 2.

PHOENIX PARK.

The far-famed Liffey, as it pours its waters from west to east, divides the fine city of Dublin into two almost equal parts. The noble quays on each side of the river extend to King's Bridge (the eighth bridge), where close at hand on the south side is the splendid terminus to the Great Southern and Western railway, built of heavy granite with its base story in the massive Tuscan, and the upper parts chiefly in the florid Corinthian style. On the north side the quay terminates in Park Gate Street, and a few minutes bring you to the gates of the Park, *par excellence*, in the British dominions.

The size of the Park is great, containing as it does 1750 statute acres. The surface is greatly varied and diversified, showing at one place extended level platforms, and at another place deep, picturesque glens and gorges, and elevated mounds and hills. As a whole it is admirably planted, though still leaving room for the exercise of the refinement and thoughtful consideration of the landscape-gardener.

There are fine old trees to be found that have witnessed the days of other times; but in this respect it must yield the palm to the massive grandeur of Kensington, and the hoary dignity of Hampton Court. That grandeur and dignity, however, are becoming associated with the coming decrepitude of age; while in the case of the Phoenix we are almost constantly presented with the ever-growing, luxuriant buoyancy of youth. As respects variety of scene and variety of object, there are few points on which to base either comparison or contrast—the Phoenix has it all its own way.

Almost every kind and variety of deciduous hardy trees have been brought into requisition. In forming the masses and groups during the last generation, the mixed system of planting seems to have been adopted, so that the more quickly-growing kinds should act as nurses to the others. So far, however, as we could judge from a passing inspection, two things have been thoroughly attended to—the thinning has been done in good time, and the work has been so conducted as to leave those trees ultimately that were intended to form the group, so that each of these groups might present a distinct and separate feature when contrasted or compared with its next neighbour. Not but that a tree or two of a different kind might not be left; and of this we noticed frequent examples, and these, if not too numerous, will ever mellow down the hard lines of contrast between groups so planted, and form a sort of connecting link between them. This variety may be secured without monotony.

We may be only groping out of the mist as respects this question of variety; but we are not so justified as not to see that on this subject a great many of our clever friends are yet densely cloud-wreathed. The whole matter requires thorough investigation and study, for we seem to have no settled principle whether the variety wished for has reference to groups of trees or groups of flowers. "What a luscious mass of foliage!" "What glaring unmeaning yards and patches of colour!" "I'll none of them—so thoroughly unnatural!" As if it were necessary to imitate Nature either in park scenery or in the more artistic garden. The appealers to Nature should just let Nature alone in her glory, and there are just enough of gardens so left to tell us what they will become. "As for me I will have only clear, distinct colours in contrast, and when you have lested your eyes on blue Lobelias, orange Calceolarias, purple Verbenas, and Scarlet Geraniums, you may just as well afterwards go through some of our finest gardens blindfolded."

"I am all for variety. Just notice if you please the wonderful variety of tints and shades I have contrived in this single bed, and so of all these fifty beds or more!" and before you get half over the number of beds the weariness of monotony and sameness comes over you, and you feel that mixture under such circumstances is not variety.

And yet in all these modes becoming objectionable and unsatisfactory when rigidly carried out, there is just enough of truth in them all to tell us that our perceptions of the delightful will not be satisfied with looking on merely one form or combination of the beautiful. Thus there are four hill sides which we have seen covered with timber, the soil and climate being such that the first crop was to be Larch or Scotch Fir, or both. One was planted with Larch; another with Larch and Scotch, tree for tree; another in squares of each; and a fourth in irregular masses of each separately. The one kind running into the other at the points of junction. All were pretty equal in point

of profit. But there was no comparison of the view as a pleasing picture. The two first were monotonous; the third prim and stiff in outline; the fourth gave diversity, contrast, comparison, and yet formed a beautiful picture as a whole, on which the eye never tired resting.

Thus with this noble Park. If it had been planted chiefly with one kind of tree, be it Oak, Chestnut, Elm, &c., however massive in dignity, there would have been monotony in foliage. If a number of sorts had been planted, mixed in nearly equal proportions, there would have been no variety in the diversity. There would have been variety but great stiffness, if each kind and variety had been kept in its little circle or square entirely by itself; but so plant that one kind of tree shall greatly predominate in one place, according to situation and soil—say, here the White-barked Sweet-scented Birch; there the trembling-leaved Poplar, meeting its next neighbour among the taller Limes, followed in turn by Plane trees and Maples; and these, again, joining Chestnuts, Oaks, and Beeches, with fine specimen Thorns and Hollies on the deep upland soil, and dense woods of Thorns in the glens; whilst masses of the Bracken and other Ferns grow luxuriantly in the shaded, moist, rich spots, and little Heathrubs of various kinds take possession of the steep braes and mounds (that would be called hills and mountains in London, Primrose Hill to wit), in all such places where the Clematis, the Bramble, the Broom, and the Whin have not already taken possession. Then you may form an idea how the good folks of Dublin, within a few minutes' walk or drive of their customary residences, may not only enjoy in the very best way the diversified beauty of our loftiest-growing trees, but may also revel amid scenes so suggestive of the romantic and the picturesque.

"Well, it seems strangers know more about our advantages, than we do. Have driven through the Phoenix, it is true, but have troubled myself little about trees and scenery, when there was something more attractive beside me; must go again. Singular, though, not a grumble about us Dublinites; not a slap at the officials; not a fling at the Government; no lifting us up with praise and panegyric, in order that we may get a more fearful tumble down for shortcomings; no, not even a suggestion how anything could be made better or more attractive than it is!"

Not quite so fast, good friends. We speak of the impressions made on our own mind in a beautiful yet somewhat boisterous day in the middle of September. We saw so much to admire, that we could not help wishing that in this great Park of the people, if there were not floral charms, there should be more diversified and distinct forms of sylvan beauty to instruct and gratify through the organs of vision. It is only in such places where great things have been already done that you can expect still greater to be accomplished.

We may have forgotten, but beyond the private official residences we have little recollection of seeing much, or anything, in the shape of evergreens, and that, too, in a climate where they are generally so much at home. In suitable places how enchanting would groups of Portugal Laurel, Phillyrias, and Arbutus look, fronted with masses of Lamartine and Rhododendron, and backed by other groups of evergreen Oaks, not forgetting the sombre Yew, and groups by themselves of the upright Irish Yew, that seems so much at home in Ireland. Then, for imposing grandeur, why not have groups of the Pine tribe? There is the magnificent common Spruce (*Abies excelsa*), with its pretty companions, *nigra* and *alba*, not to speak of the massive broad-leaved morinda, the graceful cephalonica, the massive dark Douglas, and the graceful canadensis, or Hemlock Spruce. Then among Silver Firs, how beautiful the common Silver (*Picea pectinata*), the Palm of Gilead (*P. balsamifera*), the bristle-pointed-leaved *P. cephalonica*, the splendid *P. nobilis*, the wide-spreading Webbiana, and the close, compact, slow-growing, though very distinct and beautiful *P. pinsapo*. And then in the *Pinus* class, how interesting is even the Scotch Fir, and its many varieties (*P. silvestris*), even when young, and how more than interesting when they get bonnet-headed and old. Then there is no end of species and varieties, as the somewhat loose, Pinnar, or cluster-coned Pine; the dark massive austriaca; the round-headed Stone Pine (*Pinus pinea*); the heavy-wooded, half-tufted ponderosa; the very elegant insignis, hardly touched in Ireland, though nearly destroyed last winter north of London, in England; the long, graceful-leaved montezuma, worthy at least of a trial; the elegant Weymouth (*P. strobus*); and the still more beautiful *P. excelsa*, with its elegant glaucous green foliage, and which seems to thrive everywhere; the upright cembra; the cande-

labrum-like lario; and the large-leaved, somewhat drooping Lambertiana.

But why mention these by name, or even allude to the beautiful Arbor Vitæ (Thuja), the graceful Cypresses, the stiff Junipers, the noble Cedars of Lebanon, the still more beautiful Deodars, the striking Cryptomeria and Taxodium, the more wonderful Wellingtonia, and the marvellous beat-and-puzzle-the-monkey Pine of Chili, the Araucaria imbricata, which along with the Wellingtonia, we seem already to see occupying natural mounds, and raising their distinct forms out of thickets of Thoro, Bracken, and other undergrowths? Why, indeed? Not to stimulate the enthusiasm of the worthy veteran (Mr. Wilkie) who has the superintendence of the Park; for less than an hour passed with him in his little paradise around his cottage home—that paradise so marked alike by the rare and the enticing—convinced me that in knowledge of, as well as love for the beautiful in trees, I was a mere tyro in the presence of a master professor; and that in that quarter, enthusiasm, without which nothing great was ever done, instead of needing to be aroused, was only wanting to be carried out in practical development. Why, then? Just that the good citizens of Dublin should have such a taste as would foster the desire to obtain the possession of more diversified and unique forms of sylvan beauty, so that an almost unanimous request should be made to the Government that a small part of what they so freely tender to the State should be returned in the shape of an annual grant to carry on gradually these alterations and improvements.

Our paternal and free Government is sometimes accused of voting away the public money too freely. It would be something like a treat—a rather pleasing new sensation—did they even get blamed for giving a grant that would foster a love of the beautiful amongst masses of the people, with all its accompanying, refining, and elevating influences. The grant, if requested, will be liberally responded to, because we have no doubt that sooner or later the work will be done; and we hardly expect that the State will so willingly deprive itself of its influence and authority as to have it carried out by the people themselves, either by the help of a local rate or a voluntary subscription. One thing, however, should not be forgotten—life at the longest is short and uncertain, life cannot be long after the head turns grey; and, if not commenced early, the stored-up observation and experience of a lifetime of one who has made trees and shrubs with their distinctive features, and suitability to different positions as respects exposure, soil, and climate, his enthusiastic study may for all such improvements be lost and unavailing.

When we thus advocate giving to this Park a more diversified character, we would not wish to make much, if any, alteration with the timber now existing. We have no desire to see anything formed in the way of a regular pinetum—we would rather discard anything like regular arrangement. To us a large pinetum, with nothing but the Pine tribe in it, is about as dreary as a large fernery with nothing else to break in on the monotony. In such a case we have often been glad of a white flint stone for giving a little relief to the scene. A few fine bright-foliaged plants would in such a position effect wonders. On the same principle a group of the Pine tribe, or even a few specimens, appear to most advantage when near a group of deciduous trees. Numerous opportunities for such groups will be given without much interfering with existing arrangements.

One other great feature in this Park is its roads—miles and miles of them—and yet most of them so firm and dry from being gently rounded, that there scarcely seemed foothold for the hardy and hard corned-horses of the public cars, furnishing in this respect a great contrast to most of the garden-walks round Dublin, which, being made of shingle from the river or the sea, must in its shiftness be a rare benefit for tender feet, or those having any such a thing as a corn or a bunion. We were rather amused at seeing near one of the private lodges a large placard, with "Keep off the grass" printed in large letters, as if any one would be silly enough to go off such a bowling-green of a road, to disport himself or herself in grass pretty well high enough to reach the knees, and that, from dews and rains during the end of autumn, generally in a moist condition.

Unlike what takes place in London and other British cities, where rank, fashion, and fortune, flock to the West, the neighbourhood of the Phoenix did not seem to get more than its share. There is little of the architectural to demand attention, except, perhaps, the Military Hospital, a little past the gate to the right, and the Constabulary Barracks farther on. The

Zoological Gardens make no pretensions in this respect, though rich in a general collection, and especially rich in rare Irish birds. The chief thing in the way of building that every one cannot escape seeing, is the noble obelisk a little inside of the gates on the left side of the road, raised as a testimonial of love and respect to the Duke of Wellington by his Dublin fellow townsmen, in 1817, and at a cost of £200,000. The beautiful cast bronzed reliefs, have only lately been added to the four sides. Above these reliefs, to the top of the obelisk, at something like regular distances, the names of seven battles are inscribed on each of the four sides—Waterloo is not among them. Was it thought that here the Duke owed something to the prowess of others, as well as to the bravery of his officers and men, and his own genius and well-matured plans and combinations? In these piping times of peace, we are apt to forget our obligations to the great hero whose heart so nobly throbbled with love to his country, and the resolute determination that, come what would and oppose what might, he would do his duty. That last word reminds us of the stirring signal sent through the fleet by the great naval hero, "England expects every man to do his duty!" Why was not the beautiful Nelson monument, built by the free, fair, offerings of Irish admirers, not likewise placed in this Park for the people; instead of standing as it does in the middle of unequalled Sackville Street, cutting that fine street in two, and marring the effect of the two streets which join it at right angles? Then our youth might look alternately, now on one monument, and now on the other, and feel their souls fired to imitate their heroism and patriotism, whenever their country should be exposed to danger.

"What! thus encourage the passion for war?" No; but so long as we consider it necessary to bolt our doors, and bar our shutters, so long will it be necessary to have the sword of the soldier in reserve to give efficacy to the baton of the constable. When lusts shall be controlled, and evil passions eradicated, and justice, and goodness, and purity triumphant, then we shall expect to have peace universal and permanent. But even now, if such a noble Park is to be made the scene for monuments to the heroes of warfare, we see no reason why, like some of our cathedrals, the objects of the admiration of a people should be confined almost exclusively to men of the warlike camp. Monuments, we sometimes think, are erected as much to gratify the vanity of the living as to commemorate the worth of the departed; but if monuments either to the living or the departed are to be the order of the day, then let us in this beautiful Park have monuments to the heroes of peace who did something to spread an elevating, refining influence over Ireland—monuments to the heroes of design and invention, that have made the wildest aspirations of the magic of old the practical realities of everyday life—monuments to the heroes who by means of cars, coaches, and railways, opened up the resources of their country, gave an impetus to its commerce and its agriculture, caused two or even three blades of grass to grow where only one grew before, and placed the large loaf instead of a very small one on the table of the industrious workman—monuments the finest and the best to those philanthropic Irishmen, who in the hard times unflinchingly stood at their posts of influence, and dreamed not of any sacrifice being too great, if only that the comfort and the well-being of their neighbours could be promoted. R. FISH.

IMPROVING OLD VINE-BORDERS.

I HAVE two Vine-borders that are very wet; they were not covered last winter, and the fruit shrivelled up this summer most miserably. They are of the old sort of borders, about 4 feet deep of solid wet soil. There are a good deal of bones in them, and the Vines have made first-rate wood, which is now ripening nicely. I have covered the borders with boards this last week 5 yards wide and about 1 foot off from the ground, so there will be good ventilation to dry it a little. My employer wishes to have the Vines started early next season, but I am afraid to do so. The Vines are about sixty years old. I thought of taking the covering off at Christmas, putting a regular good heap of horse manure on the roots, covering up again, and then starting the branches in another fortnight or so.—ONE IN A FIX.

[The first thing you should do is to have a deep drain sunk in front of your border at least 3 feet deeper than the bottom of that border: this will drain it. The precautions you have taken in covering the border are good; but by the middle of October or

so we would stuff beneath the boards, or, rather, we would raise the boards, and place from 12 inches to 18 inches of fern or dry litter over the border to keep the heat in, instead of having so much fermenting matter put on the top. We would do this with the pot to be forced early. In addition to this, if you find on examining that there are few roots near the surface on your border, it would be well to remove a portion of the exhausted soil on the surface until you come to roots, and put a little fresh soil over them, and then give a little heat to the border with fermenting materials when you commenced forcing. This would draw the roots up into the new soil. If the surface soil is filled with roots, only cover as proposed.]

THE MISTLETOE GROWING ON THE OAK.

WHAT CAUSES VARIATION?

ONE would have thought that to prove a fact once in one's lifetime would be enough; but some of the Druidical witchcraft still clings to the Mistletoe, to all appearances, in the vicinity of our seats of learning, and one fact has to be proved over again every twenty years or so, as the subjoined correspondence will show.

I had a printed circular enclosing a return paper with printed headings to be filled up, from William Marshall, Esq., Solicitor, Ely, Cambridgeshire, as to whether the Mistletoe (*Tisum album*) ever grows upon the Oak?

The following answer I sent by return of post, and I hope it may keep you in the far east at ease for another quarter of a century, and that all others whom the question may concern will have better memories than some of the Cambridge people:—

Dear Sir.—You are breaking a bit early on the wheel. Every practical botanist who can read English might have known that the question of the Mistletoe growing on the Oak had been set at rest a quarter of a century since by Mr. Loudon and your humble servant, and the way we did it was published all over Europe and America at the time. But here is a résumé of it:—I sent a 3-inch diameter cut from an Oak in the park of the Earl of Somers, at Easton Castle, Herefordshire. I sent it and a large piece of the Oak branch to Mr. Loudon, and Mr. Loudon exhibited the Oak branch with the large Mistletoe plant attached to it before the Horticultural Society of London. I do not know any practical botanist who saw the specimen. Mr. Lindley is not a practical man; but there says he is a first-rate botanist, and he certainly saw that specimen and lectured on it before the Horticultural Society of Reading.—I am, &c., D. BRISTON.

I had just finished reading Mr. Anderson Henry's most interesting communication on variegation, cross-breeding, and muddling of plants, when the Cambridge circular was handed in to me; and to keep on the square, and on the centre of gravity, I replied first to Mr. Marshall to clear an old score out of an old story before venturing on things original with a most welcome cordiality to the page 8. If I had all my life crossed everybody who came near me, I do think you might excuse me and my crossing for having even tempted two such rival philosophers as Mr. Darwin and Mr. Anderson Henry, to contribute to our stock of practical science in THE JOURNAL OF HORTICULTURE. I have said already that all the difference of opinion about the disease of variegated plants was in the meaning of the terms, not in the thing itself.

I have seen the "OLD SPOWMAN," and had some long conversation with him on these matters. He is a very practical man, and there is a man who cannot give his name. Instead of writing a foreign name at anybody's elbow, he went to work like a true philosopher, and I instituted experiments in reference to all the terms which he used from his own. Instead of yarning or yarning about uncious and obscure points, he went and asked Nature how they stood in her story. It may be a long while ere he will get an answer, and meanwhile I proceeded to go to see his experiments.

To accede to my experiments—say ten thousand trials, in nine cases out of ten there is actually less disease in a variegated plant than in the green plant which produced it. It is not disease, but a certain "disease" for which we have no name nearer than the word "disease." The way I prove that is this:—the like produces the like in the natural and variegated kingdoms. A noble lord whom I had known, had three sons, one very spirited was killed in the continental war, the other two lived to over seventy years, and one of them only had a son, an only son. The grandfather was a powerful specimen of the true English gentleman; the grandmother was from a very healthy stock, and she lived to near eighty; the father, mother, uncles, and aunts were all remarkably healthy, and all very large in bone and muscle; but the grandson is a dwarf, now in the

House of Lords, perhaps the smallest personage there, but he is very healthy and always was, except once, about his coming of age he had some severe illness. He travelled in all climes. I knew his valet, and he often told me his lordship, notwithstanding his small size, was in the best health of the suite in Syria, in Egypt, and all along on both sides of the Mediterranean. Now, the cause assigned for the extraordinary difference between my lord and his family east is, that "his growth was stopped by that illness." But he is in fact on the same footing in that respect with one of my variegated seedlings, very different from his parents, but as healthy and as free from any sort of disease as that member of the Upper House. He has three children who, to all appearance are as healthy as larks.

Well, "that illness" whatever it was, works in the vegetable kingdom exactly in the same way—works in making dwarfs, all variegated plants being dwarfs relative to their parents; still they are as healthy and just as capable of producing a healthy offspring as any green species or variety of the race—I mean the race of *Pelargonium*.

I raised thirty thousand seedlings from the different Variegated Geraniums, beginning with the Golden Chain; and I had less variegated seedlings amongst them than from an equal number of seedlings from green parents.

In six years I raised twenty thousand seedlings from Punch by its own pollen at Shrubland Park, and never saw a single variegated leaf among them all. Here, at Surbiton, no matter which pollen I use on Punch, one-third of the seedlings from it are sure to be blotched and half variegated, and no Geranium is more free from disease than Punch.

In 1853-4 I had some hundreds of seedlings from Flower of the Day by pollen from other variegated sorts, but not a blotch did I ever get in the seedlings; and if Mr. Anderson could give me the white kind which produced all variegated seedlings with Tom Thumb, I am all but quite certain I could get every one of the seedlings from that same cross to be as green as true seedlings from Tom Thumb—that is, after growing the two for one season in my soil.

I had the first of the present race of white-flowering Geraniums in 1846, and I crossed many of them the three following years with the Crystal Palace Scarlet and with Punch, but never got a variegated plant or a good flower in these crosses; but the rose-coloured ones, as Judy, Lady Middleton, and another unnamed rose kind, produced useful flowers with the white race, the Zonale alba, as it was then called. Shrubland Green and Tricolor were the best of that strain, but they are only house plants and did not obtain much circulation.

Mrs. Vernon is the strongest and most healthy of all the Nosegays, but on my soil no batch of seedlings from it by its own or other pollen comes without several blotched sorts; therefore, I cannot withstand the evidence of my senses against any variegated Geranium whatever being the result of any form of disease.

I have one plant now which was a poor, puny thing from the seed-leaf, a seedling from Baron Hugel by a wild dwarf seedling of my own—an extreme cross as we say. It was three years old before it bloomed in 1859, and it is a very shy bloomer, but it is my principal breeder for minimus; and if poverty of constitution could be called a disease, here is a diseased kind to all intents and purposes, and yet with all our variegated kinds it will not throw off one blotched leaf in any of its seedlings. It will be the father and the mother of a new race of so healthy and free-growing seedlings as Punch, and none of them will ever rise to the stature of the Golden Chain. The first of that dwarf breed will be in the market next spring by the name Harry Heaver, after the author of "Table Talk and Stable Talk," a charming writer on horses. Harkway was one of his favourite runners, and this seedling is from the Harkway Geranium by the pollen of my dwarf.

Pray let me believe in this disease question by Harry Heaver as soon as it is out, and try it with the pollen of any of your diseased seedlings. It is the most minute of the race except Dandy, but is as good a seeder and as free a grower and bloomer as ever was planted out; therefore, it must possess less constitutional powers than any except Dandy; and if there is truth in your disease conceptions, this is the kind which is the most likely in the world to produce diseased seedlings, if it is crossed with diseased male parents. There never was a better chance to prove the question than when you have a great brood of diseased seedlings. Tell me the name of the male parent and I shall repeat the cross with it, and shall lay my head on the

block if I do not reproduce the same crosses just as green and horseshoe, and quite as healthy as Harry Helover. I have that confidence in my soil. The diseased plants failed in so many instances to transmit their taint in this soil, that I am justified to make so bold upon it. The American blight which cripples the Apple in the orchard is not a disease, and cannot be transmitted like the canker, which is a true disease, and never fails to appear in the seedlings sooner or later. But the American blight stunts the trees woefully, and so does the blight which produces variegation.

Dr. Morren's vast explanations are just so many airy nothings. Ideas and surmises shall never controvert facts, and the fact is this—give me the two most diseased plants of Germanium in cultivation, and I shall cross them and confute with the progeny all the high ideas of continental philosophy about this disease. Of that I am quite certain.

Did not Mr. Anderson read as much nonsense about crossing, three or four years back, from a British pen of un doubted scientific strength? and might not some sober people on the Continent who were conversant with the simple facts by practical experience, marvel that such ideas were current in England, just as I was amazed with Dr. Morren's elaborate review? Depend upon it, we are all of us wrong in pinning faith in high-sounding disquisitions from great men, and in overlooking the low and slow progress and process of the simple practitioner who may not know how to put three ideas together in black and white. But a clever practitioner at his pen might very easily go over Dr. Morren's formulae, and confute them by actual examples, one by one, from beginning to end. I may be partly wrong, but I recollect perfectly well that my impression was on reading the article, that I could myself smash many of his best foundation stones to splinters.

Dr. Herbert was the first scientific writer in this country who propounded the doctrine that the world was clothed from the produce of a very few kinds of plants, in his first book on bulbs in 1821, or about that time. In 1833 he resorted to the subject more largely in his "Amaryllidaceae" and when he was persecuted for an atheist, and made to be the author of the "Vestiges of Creation," he vindicated his fame, and gave glimpses of his vast experience on that subject in the Journal of the Horticultural Society, where he exhausted the subject.

But, in conclusion, I have yet some hopes left me that I shall some day discover the true and real cause of variegation in plants. I had a point or two solved in rubbing shoulders with "OLD SHOWMAN," who is all but a Darwinian from top to toe. I must find time to run down and see him, however, before I can say aught aient that part of the subject; but if I understand him rightly, he will not long cling to the notion that men can change a blade of grass from one form or colour to another, save through the process of Nature by fertilisation.

D. BEATON.

NOTES ON SOME OF THE FRENCH NURSERIES.

PARIS, OCT. 10.—While Mr. Fish is doing what Topsy would call "telling his spinners" as to Ireland and her horticultural position and prospects, it may not, perhaps, be uninteresting to some of your readers to hear a little about the doings on this side of the water. We so look now to France for Roses, Gladioli, Phloxes, and other flowers, that if people are of my mind it is always a point of interest to know a little about the folks and the localities from whom and whence they came; and if pilgrimages are made to certain spots where people have died or are buried, surely we who, perhaps, take as much interest in a living nurseryman as in a dead hero, may be excused if we think there is something a little more rational in visiting those who can talk and act. Of the former we may say—

"The knights are dust,
Their good swords are rust,
Their souls are with the saints I trust."

But with the latter we can shake hands, talk bad French, and have horticultural talk as best we may; for amongst other things which the English Trojans (*vide* "Cornhill Magazine" for this month), have imported into Paris, a Trojan Nursery is not numbered.

The impression that one has of a Parisian horticultural establishment (I have not as yet seen the provincial ones), is not of the very liveliest character. They are small, untidy, and

the appearance of the greenhouses is more that of a series of pits than of what we are used to in England; and one's idea at first was, these good people have a good deal to learn about greenhouses' construction. But a more careful consideration of circumstances showed that such an idea is wrong. Our great object is to obtain as much light as possible, that of the Paris nurserymen to exclude it. The hot glaring sun and the brilliant clear atmosphere of the city, coupled with the white gypsum of the soil, would be too much for the plants in structures like ours; and hence nearly all theirs are grown in low span-roofed or lean-to houses, the walls thick and the panes of glass small.

The size of the nurseries indicates, I should suppose, a comparative smallness of enterprise, or, as one of them said, "I must creep on little by little." Though in most instances this, too, is deceptive; for many of them have three or four different pieces of ground in various parts of the environs. Ground in Paris is now becoming so extravagantly dear, that shortly they will, they say, all be driven outside; and hence it is that one sees, even with some of the first houses here, a piece of ground which would only satisfy a third or fourth-rate nurseryman in and about London.

There does not seem to be that continuance in the calling which we see on our side. In many of our large establishments it goes on from father to son through generations; but here, so they tell me, the position of a nurseryman is not like what it is in England, and, if the father makes money, the son considers himself too good for his father's business. But there is another matter which has a good deal of influence in damping energy in this country—namely, the laws of succession. A man may toil and labour all his lifetime, may get a fine property together, but at his death it must be divided amongst his children. Happy, therefore, the Frenchman considers himself if he has but one boy. A boy and a girl, they say, is a family fit for a king. As one of them said to me to-day, "I have been twenty-four years in this business. I have now a fine property; but after me it is finished." One must not fall into the Frenchman's falling of generalising on all matters; but it seems to be tolerably clear that such a state of things must be injurious to enterprise, and to horticultural enterprise amongst other things.

Amongst the best known of French nurseries is, I suppose,

THIBAUT and KETLEER'S.

This is situated in the Rue de Charonne, not far from Père la Chaise. Small in size, to our eyes at least, but containing a good collection of many valuable things. They are purchasers of most of the new plants which are introduced into France, Belgium, and England, and are the distributors to the public of the new Gladioli raised by M. Souhait, who grows 50,000 seedlings, and has this year introduced six to public notice, of which great things are said. Whether they will equal the Bag-hot varieties is, I think, very questionable. Amongst other things that I noticed here were some fine Erythrina, Marie Boulanger, which Messrs. Houdouin have figured in their "Illustrated Bouquet," and Floribunda, very dwarf and of a beautiful rose colour. There is also another, which they are about sending out, between these two, also very dwarf and of a beautiful rosy crimson colour, called Ruberrima. Whether we may ever look for these succeeding well in our variable climate is a question; against a wall they would probably do very well.

Amongst ornamental plants for turning out of doors in the summer, and making a fine show of foliage, I saw here Wigandia caracasana, an old plant, but now much in vogue here, and Ferdinanda elegans; both of these attaining in a single season a height of from 8 feet to 10 feet. They are to be seen in many of the public gardens and other places in and about Paris, in the greenhouses and stoves. I noticed a fine plant of E. r. r. triflora in full fruit, and a very remarkable-looking Fern—Lycopodium diotomum, the fronds hanging down in festoons almost like some of the Ceruus tribe, and unlike a Fern as one can well imagine anything to be. There was also a very pretty Orchid called Seleneodium Schlegelii, with a rosy purple labellum, small, but very neat-looking and prettily. Also Streptocarpus biflora polyanthus, a hybrid between S. Rhexii and S. polyanthus, and partaking decidedly of the character of both parents; it promises to be a very pretty greenhouse herbaceous plant. But one of the things which pleased me most was a plant unknown to me—Eucharis amazonica, an Amaryllid-like bulb, with a flowers-stem holding two or three blooms of pure white, with a cup some-what like a Narcissus with a greenish tinge on it; it was very fragrant, and altogether a pleasing thing. Their

general stock looked in good health both in the houses and out of doors.

Not far from their Nursery lives

MONSIEUR ROUGIERE-CHAUVIERE,

the son-in-law and successor of Monsieur Chauvier, to whom we were indebted for the first more in the Geraniums which have introduced so much variety into our own breeds. Mons. R. introduces into France many of the new florists' flowers brought out in England, Pelargoniums and Dahlias especially: and hence, as it was too late for these, there was comparatively little to be seen. He was, however, the purchaser of the valuable collection of Orchids of Madame Pescatore, which he added to his own already good collection: and hence he has a *spéciosité* for these plants. The finer specimens, he said, were gone; but there was still a large number, which would probably receive more attention now but for the fact that the finest collection in Europe is shortly to be brought to the hammer—viz., that of M. Schiller, of Hanburgh. Mons. R. spoke highly of a new Delphinium called Madame Gonschal, which he described as being very fine and with a beautiful white eye. Abutilon Due de Malakoff, planted out, was very fine with flower, three times the size of striatum, very freely produced, and the plant itself so vigorous that it had attained the height of 6 feet or 7 feet in the summer. He also mentioned, as a very pretty herbaceous plant, *Sakesia cranea*, dwarf, and having, as its name imports, flowers of a sky blue colour.

Here, too, there was a collection of plants in very good health, though, of course, the time of year was unfavourable for seeing them; but it was not unfavourable for experiencing the great kindness and hospitality of both of these firms. Accompanying as I did Mr. Stanbly, of Bagsbot, whose name is itself a passport, I was a sharer in the hospitality, which was, I doubt not, a return for that he so liberally dispenses to all comers at his own house; and no people can show it in a kinder and more agreeable way than the French can do.

I hope next week to say something of some of the provincial nurseries. Time and postage necessitate brevity now.—D., Deal.

SULPHUR AS A DESTROYER OF RED SPIDER

The confidence which "T. R." places in sulphur as a remedy for red spider, would almost persuade me to believe that my want of success was owing to my want of faith, knowing how efficient the latter is in assisting a remedial agent; but as the patient and not the physician must exercise the faith, and as I cannot suppose that plants may be induced to believe in sulphur, I am obliged to look elsewhere for an explanation of results apparently so totally at variance as those mentioned in the previous letters on the subject. My doctor often has lamented to me, that when he has treated a case to a successful issue, he cannot tell whether the patient has recovered through or in spite of his remedies. This remark appears to bear on the case of the Vines. "T. R." says that a pan of water covered with a thick coat of sulphur standing in a hot place under the Vines, has been for years a perfect preventive. Can he be sure that the Vines would have been attacked if the sulphur had not been there? The Vines in my house, where Peaches, Figs, &c., are infested with red spider, are thoroughly healthy, and free from the insect.

Again, for years I cultivated Vines in a house close in proximity to a large Apple tree, the north side of which was invariably unhealthy and covered with spider (the south side being as invariably healthy and clean), but the Vines were never attacked, yet not an atom of sulphur or any other remedy was used as a preventive. As to the Peach trees in the ground viney mentioned in "T. R.'s" letter, I cannot help thinking that another and much more efficient remedy was at work simultaneously with the sulphur applied as stated in the first week in July, for at that time rain began and continued to fall during the whole of the month. Healthy root action, probably, in consequence commenced, and soon rendered the trees distasteful to the insect. According to my observation neither aphid nor red spider will attack a thoroughly healthy plant. The insects are not the cause but the consequence of disease.

I speak from experience and not from theory as to the effects of sulphur in Melon-frames, and I can only say that the shoots which grew over the pan of sulphur alluded to in a previous letter were as thickly covered with the insect as the other shoots—in fact,

more so, for one plant on the other side of the frame remained comparatively clean. In my house, which is only 33 feet long, there is a tank of water with an exposed surface of 20 feet by 3 feet; this, with frequent syringings, must afford a considerable amount of atmospheric moisture, which combined with the vapour of the sulphur strewn all over the house, ought, according to theory, to have been sufficient for the purpose; but the facts, unfortunately, would lead me to conclude that the combination was congenial to the insects.

I will mention one amongst the numerous instances which have come under my notice, tending to prove that the attack of the insect is more dependant upon the state of the root than upon atmospheric influence. I planted in the middle of a bed of Strawberries in a large pot without a bottom, sunk into the ground to within 6 inches of the rim, and filled with good soil, four Strawberry plants, and watered them regularly, while all the surrounding plants which were growing on a subsoil of porous sand, and were not watered, dwindled away, the little sap they managed to elaborate from the dry ground being sucked out of them by my voracious enemy. The four plants in the pot rejoicing in the deeper soil and regular watering thrived, and up to the present time have repelled the insect.—E. T., *Solihull*.

CAMELLIAS BLOOMING PREMATURELY.

Will you help an old subscriber who is in trouble with his Camellias? They are one and all in full bloom. They were potted the beginning of July, and set out of doors behind a north wall. They were in a cold greenhouse before they were potted. What am I to do with them after they have done blooming? They are out of doors yet, and look well behind a north wall.—YORKSHIRE.

[The fine season has brought your Camellias forward, though there are not many quite so forward as yours. You have no reason to be alarmed about them. House them, and keep them in the house in the usual way, only perhaps you need not mind forcing them to make wood early next spring. Most likely they will incline to come a little earlier for some years to come so as to bloom regularly at the end of autumn and the beginning of winter without anything like forcing at any time.]

MECHANICS AND MATHEMATICS APPLIED TO GARDENING.

(Continued from Vol. I., page 403.)

THE SCREW.

THIS is a compound mechanical power; for it is useless unless set in motion by a lever.

A screw is an inclined plane passing spirally around a central spindle. It may be represented accurately by dividing a piece of

to the next spire is called the *breadth* of the screw. When the thread round the cylinder is elevated or raised, it is called a *male screw*. If the male screw is fitted into a solid having a spiral groove within it, corresponding precisely with the thread, that spiral groove is called the *female screw* or *nut*.

It is the combination of these, set in motion by a lever, that constitutes the mechanical power of the screw.

The only application of the screw to gardening purposes that

we have seen attempted is in the extraction of stumps of large trees, but we do not remember the result.

In hydraulics there is an application of the screw form which might be employed by gardeners with great advantage in raising water to a higher level. It is called *The Screw of Archimedes*, and sometimes the *Archimedean Spiral*.

Archimedes' Spiral is either a flexible tube open at both ends and wound spirally on the exterior surface of a cylinder; or it may be a plate of metal coiled about an axis, like the threads of a screw, and enclosed within a hollow cylinder, so as to be completely water-tight. The machine is fixed in an inclined position, with its lower extremity immersed in the water which is to be raised. While it is at rest the water occupies the lower part between two of the threads, or bends of the spiral, at bottom; but, when turned on its axis, this part of the machine being made to ascend, the water will by its gravity be caused to descend into the lower part between the next bends of the spiral, while in reality it rises, with respect to its former position, in consequence of the rotation of the tube, or bends, within which it is confined. Thus the water continually proceeds towards the upper part of the machine, from whence it is discharged into a reservoir placed to receive it.

It is shown, by writers on hydraulics, that this machine cannot raise water when the angle which a line drawn centrally on the spiral bends makes with planes parallel to the base of the cylinder is greater than the angle which the latter makes with the horizon; and it is recommended that, in practice, the angle which the axis of the cylinder makes with the horizon should be between 40° and 60° . Such a machine is particularly useful when the water is mixed with gravel, weeds, and the like, which would spoil the action of a common pump.

As it is desirable to understand what an Archimedean Screw can effect, we aid our readers by stating that if the diameter of the barrel round which the tubular screw is coiled be 1 foot, and its length 30 feet, and the diameter of the tubular screw is 3 inches, then, if the tubular screw forms thirty-seven spirals round the barrel, it will contain of water rather more than 191 lbs. avoirdupois. It will raise the water to a vertical height of nearly 27 feet; and the force or power to turn the barrel or cylinder, applied at its circumference, will be just over 44 lbs. But, if the force acts by a winch at the distance of 10 inches from the axis of the barrel, the requisite force will be only $26\frac{1}{2}$ lbs. If it makes a rotation once in five seconds it will raise nearly 3719 lbs., or about $36\frac{1}{2}$ gallons, of water in an hour. If the velocity is tripled, which it may be without being fatiguing, nearly 1094 gallons will be raised nearly 27 feet in an hour.—(*Gregory's Mechanics*, ii., 350.)

WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from page 50.)

CRUSTACEA—(continued).

THE GREAT CRAB (*Cancer pagurus*).—The shell of this species is of an oblong form, and is minutely grained on the surface; the anterior feet are large, strong, and smooth, and destitute either of spines or tubercles; the remaining feet are slightly compressed, and furnished with a quantity of stiff hairs. Its colour on the upper surface is a reddish-brown, on the under surface white, the legs of a deeper red, and the claws black.

This creature, having from its superior flavour been in con-

siderable demand, has also become the subject of more careful investigation, the result of which is that its habits and the places it frequents are better known and understood than those of most other species. It is to be found on all our coasts, preferring the more rocky portions. Its customary retreat when not engaged on a foraging expedition being a hole in the rock, small ones may be seen continually in the pools left on the sands when the tide has receded; the larger ones keep farther out at sea, frequenting the rocks in deep water. They are also fond of burying themselves in the sand, but always in the close neighbourhood of the rocks. The mode of carrying on the Crab-fishery is simple—nor can I do better than extract the interesting account given of it by Professor Bell:—

“The fishery for these Crabs constitutes an important trade on many parts of the coast. The numbers which are annually taken are immense, and as the occupation of prooeuring them is principally carried on by persons who are past the more laborious and dangerous pursuits of general fishing, it affords a means of subsistence to many a poor man, who from age or infirmity would be unable without it to keep himself and his family from the workhouse. They are taken in what are termed ‘crab-pots,’ a sort of wicker-trap made by preference of the twigs of the Golden Willow (*Salix vitellina*)—at least, in many parts of the coast on account, as they say, of its great durability and toughness. These pots are formed on the principle of a common wire mouse-trap, but with the entrance at the top; they are baited with pieces of fish, generally of some otherwise useless kind, and these are fixed into the pots by means of a skewer. The pots are sunk by means of stones attached to the bottom, and the situation where they are dropped is indicated, and the means of raising them provided by a long line fixed to the reel or pot, having a piece of cork attached to the free end of the line; these float the line, and at the same time serve to designate the owners of the different pots—one, perhaps, having three corks near together towards the extremity of the line, and two distant ones; another may have one cork fastened crosswise; another two fastened together, and so on. It is, of course, for their mutual security that the fishermen abstain from any poaching on their neighbours' property: and hence we find that stealing from each other's pots is a crime almost wholly unknown among them. It is at Bognor and Hastings, and in Studland and Swanage Bays, in Dorsetshire, that I have principally had opportunities of personal observation on these points. If the Crabs,” the Professor proceeds presently to say, “are not wanted immediately on being taken out of the pots, they are placed in store-pots, which are of the same form and materials as the others; but considerably larger. They are conveyed to great distances—as far, for instance, as from the coast of Norway to the Billingsgate Market in well-boxes, which are of wood very strongly constructed, and with holes in all the sides to admit of continual change of water, as the boxes are drawn through the sea attached to the vessel.”

My object in making this extract is, that should any of my readers previously unacquainted with the mode of “Crab-fishing” happen in their wanderings to fall in with the process in operation, they may be in some measure familiar with the means used; and, consequently, feel more interest in watching it. The food of the Great Crab is for the most part of an animal kind, such as dead fish and the like, and it is supposed that it detects the presence of food by the smell rather than by the sight. It is also said that the bait which so often attracts it must be quite fresh; but this is not only discountenanced by Professor Bell, who says that he has “often seen Crabs taken with Lobsters in pots, in which the bait was far from being sweet,” but would appear to be further improbable from the fact of its principal food consisting of dead fish, a large quantity of which lies for days and days, perhaps, before it is discovered and devoured.

PILUMNUS HIRTELLUS.—The shell of this species is smooth, its breadth greater than its length, in the proportion of seven to ten. The anterior legs are remarkably powerful, thick, and rounded, but they are by no means equal in size. In some specimens you will find the right, in others the left the larger. The wrist is covered with tubercles, and is provided with a single spine, being at the same time slightly hairy. The smaller and fixed claw is of a triangular form, strongly toothed and having tubercles on its upper and outer surface, whilst the larger and moveable one is very nearly quite smooth, and very much curved. The remaining legs, which are covered thickly with hairs, are slightly rounded above, depressed beneath. In colour most of the species are of a brownish-red, spotted with a dull

yellow. The anterior legs are also a brownish-red, the claws a light brown; the other legs are red with yellowish bands.

The *Pilumnus hirtellus* is a species very commonly met with along the whole of our western coast, and very frequently on the south coast also, as it has been taken in Cornwall, and on the coast of Devonshire, Dorsetshire, Hampshire, and Sussex. It is found under stones at low water, and may be taken in the dredge in deep water. Professor Bell mentions a singular fact in connection with this species—namely, that amongst twenty or thirty specimens he found only one female, and that a dead and mutilated one.

PORTUNUS VARIIGATUS.—The shell of this species bears some resemblance to a heart, marked with elevated, closely-set, and minute dots. It has four teeth on each upper side, and three in the front, that in the centre being longer than the other two. The anterior legs are of moderate size and length, rounded on the outer sides and flattened on the inner; both claws, the moveable and immovable one, are toothed, the remaining legs are slightly compressed, and being terminated by a swimming-joint proves that their possessor is an inhabitant of deep water. In colour the *Portunus variegatus* is of a "pale, dull, purplish-white, mottled with a darker hue." It is a beautiful species though not a very common one. It is found, but not in any considerable quantities, on the western and southern coasts, and is occasionally found in Ireland, "thrown ashore on extensive sandy beaches." It is frequently taken by digging down beneath the sand at low-water mark.—W.

(To be continued.)

BEDDING PLANTS IN A GREENHOUSE.

DISTINGUISHING GERANIUMS—STARTING BULBS.

My greenhouse is a lean-to, with stages up the back, a flat stage in front, and three bears is hung about 1½ feet from the rafters: which sort of bedding plan will most require to be near the light?

How can I distinguish *Pencil*, *Tom Thumb*, *Trentham Scarlet*, and a pink *Geranium* cuttings? My old man mixed about four hundred of them in my absence yesterday.

Starting *Hya* initials, *Van Thol Tulips*, *Narcissi*, *Seillas*, *Snowdrops*, and *Crocuses* now, as "E. V. M." advises, will any of them flower before the end of January, not forced? and which would bear forcing best?—CLERICUS.

[Young *Geranium* plants, *Verbena*, *Petunias*, &c., require most light. *Calceolarias*, if kept there at all near the light, should stand on damp moss.

Though we could distinguish the *Geranium* cuttings ourselves with a little trouble, we could hardly tell you how to go about the matter. Let all grow as they are until the spring, and separate them as they show flower, when flowers and leaves too will be more distinct than now.

Unless the weather should be very mild, the bulbs you name will not be in flower in January. *Snowdrops*, *Crocuses*, and *Seillas* will come first, and these do not force well until the flower-stem appears. *Hycinths* and *Tulips* must be forwarded by one or several of the methods frequently referred to.]

CONVERTING A PIT INTO A SMALL FORCING-HOUSE.

I HAVE a pit 20 feet in length by 6 feet wide, which I want to convert into a little forcing-house for a few bulbs and other plants for winter flowering, also to keep a few odds and ends of stove plants until the end of January, when I intend to shift them into another house, and devote this one to Cucumbers. I intend heating it by a flue. I have a plan in contemplation, but before commencing operations I shall be glad of a little of your advice about making the flue, hot-air chamber, bed for Cucumbers, &c. I want a path inside next the back wall. I can use dung along the front wall next the hot-air chamber if you think it an assistance.—AN OLD SUBSCRIBER.

If you place your furnace at one end at the back, the flue, as a good broad one, for 6 feet or 7 feet built brick on bed, may proceed along the front across the other end and up a chimney there. A narrower flue would do if you merely took it along the front and returned it again to a chimney over the furnace. In this latter case the flue should not in both cases be level, it should rise gently—say 3 inches or so to the farther end, turn

there with a curve, and rise thence 3 inches to the chimney. This will insure good draught. You would require a path-way say 2½ feet. A brick wall a brick thick would separate this path-way from chamber and bed over the flue. Openings should be left in the wall—say five, 1 foot long and 6 inches wide, to let the heat from the chamber into the house directly as wanted, being provided with sliding shutters of wood. The bed left will be quite wide enough for the roots of Cucumbers. To save room behind, a shelf or two may abut against the wall, and a shelf be suspended from the rafters over the path—all of which may be removed in the Cucurbit season. If there is much frost and the front wall exposed, and you can keep the rain from it, the lining of fermenting dung outside will be an advantage; if not, it will be more trouble than it will be worth, and you must guard against all openings if you use the dung in a rank state, or it may serve out your plants, and Cucumbers too. By using the means frequently referred to you can have dry heat or moist heat from your chamber at will.

BEDDING PLANTS AND BEDDING-OUT.

THAT our present bedding-out system is a great improvement upon the past no one can with any degree of truth deny. Strides as rapid have been accomplished as with travelling. We are no longer content with the "old coaching on the road," neither would our employers be well pleased to find the same arrangements carried out in their flower gardens which were adopted some thirty years ago. We are now expected to accomplish great things in the bedding-out line: we are not only expected to have large masses of brilliant colours, but at the same time are expected to arrange those colours creating a harmonising contrast. Having written thus far, we have not the least hesitation in making the assertion, that all this is accomplished in scores of places in the three kingdoms. But out of all this arises the question, Have our means kept ratio with the progress expected? We are only, alas! too, too sorry to add a negative here. We are now expected to turn out as many thousand bedding plants in May as our forefathers turned out tens, and exactly with the same means; no more accommodation in the way of glass, not a little more labour—in fact, no more anything, and we should much like to see the subject well ventilated in the garden literature of the present day, and the claims of "the craft" brought before the public. Let THE JOURNAL OF HORTICULTURE be the pioneer.

When we began this paper our object was to make a few remarks on various styles of bedding-out we adopted here this season; but having so far digressed from the subject we must be brief, and should such be found worthy to grace the pages of your Journal, we may again at some future time furnish further matter, especially as we see from time to time various correspondents giving their practice in detail upon a subject full of interest to all true lovers of a well-kept flower garden, which is one of the most beautiful scenes we can gaze upon.

In the west of Scotland where we are, this season has been one of the worst imaginable. We have not had six continuous fair days since the month of May, consequently bedding plants have suffered terribly; still we are surprised to find certain plants do so well. Notwithstanding such repeated drenchings *Calceolarias*, as a whole, have been all we could desire, and up to the time we write (Oct. 13th) are finely in bloom. We find *aurantia multiflora* our best yellow. We grow *aurea floribunda*, but the former has beaten it here this season. *Amplexicaulis*, which has many objectors, and is discarded by others, makes a most effective bed here, its only fault is its "legginess." The same rule applies to *Sultan*, but for all this his sable majesty has been as much admired as any high personage in the garden. We grow another shrubby one called *Purple Gem*. This makes a splendid bed, stands both sun and rain well, habit all that can be desired. *Prince of Orange*, although rather of a weakly constitution, is fine here, but most liable to be spoilt by rains. We grow various other kinds, but the above are what are principally dwelt upon both for "chain-borders," "panelling," and ordinary beds.

Upon two borders of the following dimensions—viz., 12½ feet long and 14 feet wide, we carried out the "panelling" system which, according to our taste, surpasses all other styles which exist at present. Our groundwork on one border was *Loebelia speciosa* (true); panels, circles, *Calceolaria aurantia multiflora*; edge—rust, Box, Variegated *Alyssum*; 3 rows behind groundwork—1, *Glendinning's Scarlet*; 2, dwarf *Dahlias*; 3, *Hollyhocks*.

Our other border consisted of the following material—ground-work, *Verbena Evening Star*; panels, circles, double *Feverfew*, kept dwarf by early pinching; front row next Box, *Geranium Brilliant*, spring-struck plants kept dwarf and free from bloom; three back rows—1, *Ageratum*; 2, dwarf *Dahlias*; 3, *Hollyhocks*.

Both these borders looked gorgeous notwithstanding the common material employed within every one's reach. We had one chain-border, which was far inferior to the "pannelled" ones, still it looked neat and gay; length 156 feet. Our front row was *Variogated Alyssum*; 2, *Lobelia speciosa*; 3, *Calceolaria Mrs. Beecher Stowe*; 4, *Verbena venosa*; 5, *Cineraria maritima*; finishing with dwarf *Dahlias* and *Hollyhocks*.

Upon a short border at one end of our ribbon we tried the following arrangement, which is contrast of colour with a vengeance. Groundwork *Cerastium tomentosum*; panel, ovals, *Perilla nankinensis*; front row, *Lobelia speciosa*; back, *Lovely-bleeding*, dwarf. This arrangement was pleasing to the eye, although not brilliant.—JOHN EDLINGTON, *Lennox Castle, Lennoxton, N.B.*

WINTERING GAZANIA SPLENDENS AND VARIOGATED ALYSSUM.

WHAT is the best mode of wintering the *Gazania splendens*? Should the old plants be taken up and cut back? and should they be kept in a cold frame, or in a growing heat till fit to turn out again?

Should the old plants of *Alyssum* be taken up and potted, or do you recommend taking cuttings? I have always found the cuttings of *Alyssum* very difficult to strike, and if put into a Waltonian Case they invariably damp off.—AN OLD SUBSCRIBER.

[The best mode of wintering the *Gazania splendens* is in a greenhouse, kept just as for Heaths, say in a heath-house. The old plants should not be taken up at all, but young cuttings be made about the middle of September; they root much faster than *Verbena* cuttings, and keep in the same pots all the winter easier than any other cuttings for flower-beds. But every one of the old *Gazania splendens* could be taken up; and if they were cut back, as you say, they would keep in cold frames where *Calceolarias* would do. They want no heat, and little care, but in March and April they would give cuttings enough to stock a farm; the cuttings would root then in seven or eight days in a hotbed, and in ten more days be fit to plant out, and cuttings so made on the first day of May will be fit to plant out after the *Verbenas*.

There are many *Alyssums* used for flower-beds, and you do not mention the kind you want kept; but the *Variogated Alyssum* is probably the one you intend, and if so, every word about *Gazanias* will do for it, except the spring cuttings not to be later than early in April. The best way of propagating is by September cuttings, and the best wintering place a heath-house, and the best spring treatment is to pot them singly at the end of February, and to keep them in a dry hothouse, and in a heat of 55° for three weeks after potting; then to go to the heath-house, and on shelves up near the glass. But the same treatment as for *Verbenas* will do in the ordinary way. No plant comes from cuttings more easily than the *Variogated Sweet Alyssum*. Mrs. Walton used to strike it in the Waltonian Case without losing one out of 500—that we have witnessed; but now she allows the gardener to manage the Case, and he prefers it to making a dung hotbed.]

WINTERING GLADIOLUSES—SPERGULAS FOR EDGING—GAZANIA SPLENDENS.

THE *Gladiolus* does not live through the winter in my garden, the bulbs rotting away. I have now taken up those I planted in April, and put them in layers in a box with dry sand, the bulbs not touching; the box will be kept in a dry and rather warm room. Am I right in this mode of keeping them till next April?

I find the *Spergula pilifera* makes a very neat edging for borders. I planned mine in April last, a single row of small pieces about 2 inches apart. The edging is now 3 inches broad, perfectly even on the surface, and also at the sides which were cut with the turling-iron in August to a straight line on each side. It is superior, I think, to Box, and no footstep or wheel-

barrow will hurt it. It has required no water, and now looks like a piece of velvet. When in flower it was much admired for the contrast of the clear white star-like flower resting on the green. I have some borders edged with *Spergula saginoides*, but it is shabby by the side of *pilifera*. I also use a great deal of *Sedum* acre, but it requires a row of flints or bricks set firmly in the ground, and the *Sedum* to be planted inside. It soon covers the flints, and is kept neat very easily with about twice clipping in the year, and the flints or bricks keep the growth short.

The *Gazania splendens* has flowered well with me this year on a raised bed formed with burnt bricks. The *Gazania* has grown into a compact mass, and the flowers stand out well.—KATE.

[You have done your *Gladioluses* just in the best way possible, and your account of the *Spergula pilifera* gives us a key to the reason why the *Gladioli* do not winter with you in the open ground. Your soil is too strong and too retentive of moisture for any of the half-hardy bulbs to winter safely in it; and your *Spergula saginoides* (?) which is a mountain plant needing moorish soil, does worse with you in summer than the *Gladioli* in winter. It will neither die nor look well; but it is ten to one if one person out of ten who grows these *Spergulas* and *Spergularias* has the true *saginoides*. We had over twenty samples of *saginoides* sent us from as many places, and not one of them was true, except from one place high up in Scotland. All the race grow as well and as freely with you in the coccanut fibre as all sorts of delicate Ferns; and *saginoides* is the dwarfest of them all, and has not yet offered to bloom at all. Upon a fair calculation, two plants of *pilifera* would cover as much ground in one season as five and twenty plants of *saginoides*. How does that tally with your experience?

Where the land suits *pilifera* there is no plant in cultivation which can compete with it in neatness or richness of verdure, and the more it is trod on the better it looks.

The *Gazania splendens* we consider the best yellow-flowering plant we have for large private gardens, and about one of the worst for public ones—for this reason: "The company" in private places spend the fore part of the mid-day hours in the garden when *splendens* is in its prime; then they go to luncheon, and in the afternoon out for rides and carriage-drives. In public gardens the company go in the afternoon, and *splendens* is then nodding.]

HEATING BY A FLUE A CUCUMBER AND MELON-HOUSE.

In the course of last spring I erected a house in which to grow Melons and Cucumbers. It is a lean-to house, 25 feet long, 11 feet broad, back wall 7 feet high, front wall 3 feet high. A path 3 feet wide runs down the length of the house, and is contiguous to the back wall. The bed in which the Melon and Cucumber-vines are planted extends along the length of the house, and is 8 feet broad and 3 feet deep. I trained the Cucumbers on a trellis close to the glass, and found this plan to succeed admirably. Hitherto I have employed tan as the heating material. I now propose to heat the house by means of a flue, and am anxious to know if the following plan would be likely to be attended with success. I should place a small brick fireplace outside the house about the middle of the side wall; thence I should run a flue of nine-inch glazed pipes along the centre of the earth-bed about 18 inches below the surface of it. The return-flue I propose to make of brick, which I should run along the inner edge of the surface of the earth-bed to supply heat to the atmosphere of the house, and keep off frost.

I shall be greatly obliged by you informing me as to whether you think this plan would answer? Also what depth of earth there should be over the underground flue?

[There should either be a chamber over the flue, or brickbats, stones, or slinkers over it and round it, so that the earth did not rest on the flue. The mode of doing this best has been frequently mentioned of late. By having a few air-pipes communicating with these slinkers, but not directly with the flue, you might have moist or dry heat from the flue. The most bottom heat would, as shown the other week, be useful for Melons at a certain stage. You could have moist heat in your atmosphere by evaporating-pans on your top flue. We would thoroughly alter your arrangements so far, that we would have a good stout, thick flue below the bed, and the pipe-flue for top heat.]

CONSTRUCTION OF A HOTOHOUSE—GROWING CUCUMBERS AND MELONS TOGETHER.

I DESIRE your opinion on the enclosed plan of a hothouse; but as I feel that I have no right to ask a question of merely personal interest from which your readers can derive no information, I will endeavour so to generalise mine that every one may appropriate for his own purposes so much of your answer as may suit his own case.

I propose to erect a house 34½ feet by 17 feet inside. It will

have two long beds, each about 4 feet wide, with a passage of 2½ feet between them; and to the rear, after another passage of 2½ feet, a stand for flowers or dwarf fruit trees.

The beds are to be made over hot-water conduits formed of brick, lined with cement and covered with slate.

The cemented conduits will receive their heat directly from the boiler (one of Arnott's stove boilers)—i. e., there will be no

PLAN. NO. 2

A, B, C, D, an old pit built round and floored. The hot-air chamber will not be required if there be a partition in the house.

iron pipes containing hot water carried through them. I am but a bad gardener, but I am told that Cucumbers require a moist heat and that Melons thrive best in dry heat.

I propose that the front bed shall be appropriated to Cucumbers, and that the slates covering the conduit shall be laid on without cement, so that moist vapour may ascend to their roots.

I propose to make the bed for Melons over a sort of hot-air chamber formed thus: I will cement the joints of the slates over the conduit, so as to keep in the vapour. Over this I will leave a space of 6 inches or 8 inches for hot air, which will circulate through the house by means of openings in the brickwork of the sides. Over this I will place thin flags or strong slates to support the bed for the Melons. I will raise the back wall of this bed, so that its surface shall correspond with the inclination of the rafters. In order to obtain still more dry heat I propose to have slides on each side of my fireplace, so that I can drive

the heated smoke either into iron flues placed in front of the back wall or directly into the chimney.

I hope to have Vines as well as Cucumbers and Melons; but, of course, must keep their stems free from foliage for at least half the length of the rafter. If you think that moist bottom heat will not suffice for Cucumbers, I can have a portion of the house separated from the remainder by a glass partition, and have a dry heat in one part and a general moist heat in the other. You will perceive that I merely want a plain useful house for family purposes, and not for high gardening—one in which I may expect to have Cucumbers, Melons, and Grapes, where plants may be kept in winter, and in which there may be a little early forcing. The ventilation will be by windows on pivots in front, and by shutters also on pivots in the rear: the latter will communicate with an open shed. My questions are—

Is there any reason why Cucumbers and Melons cannot be grown in the same house? I am told that the pollen of the one affects the other injuriously—is it so? If one requires a moister atmosphere than the other would you recommend me to divide the house? Have you any observations to make on the plan generally, however unfavorable?

Perhaps I should mention that the woodwork of the house is nearly complete. The rafters are to be 20 inches part, the glass to extend from rafter to rafter. The reason for my placing the floor so low is, that I take advantage of a pit already made.—N.

[1. With the general features of the plan we have no fault to find, and we are the less disposed to do so, because most people carry out their own designs the best, which is just as it should be. We will, however, give you our thoughts. At first sight the tanks seem to be too deep—a foot or more. This, for a house 34 feet long with two tanks, would give rather much water to be heated by so small a boiler—in fact, you would hardly ever heat it at all; as though 2 inches or 3 inches at the top would be warm, the lower strata would be comparatively cold. We would advise, therefore, that your tanks should be from 4 inches to 6 inches deep.

2. We have no objection to these tanks; they are capital things to work with, but you must run the ground thoroughly below them, as the best sinking afterwards will cause them to leak. On the score of economy we think that in most cases two pipes all round for bottom heat, and three or four for top heat, would have been as economical, and quite as easily regulated.

3. Both Cucumbers and Melons like a moist heat when growing. The Cucumber relishes a moist heat with fresh air at all times; because the fruit is partaken of as a vegetable in its green state. When it is desirable to ripen its fruit, a drier atmosphere would then be desirable. The dry atmosphere and a bright sun are wanted chiefly by the Melon as its fruit approaches maturity; but though the air is kept drier than usual, and the surface of the soil is kept drier than usual, to give flavour to the fruit, the roots as a whole must not be without moisture, or the fruit might shrivel instead of swell freely to its full size. In "Doings of the Week," therefore, and elsewhere, means are spoken of by which either in frames, pits, or houses, water or moisture may be communicated to the soil below, whilst the surface soil is kept dry.

4. On these accounts then, chiefly, we should advise the dividing of the house, and devoting the one end chiefly to Melons, and the other end to Cucumbers; so that without any trouble you may keep the atmosphere in either end just in the condition that the plants wanted like most at the time.

5. With tanks a foot in depth, and four outside walls exposed instead of three, we consider that for moderate forcing you would have enough of atmospheric heat, provided the sides of these tanks were thin—no thicker than a brick on edge, and at most not more than brick on bed; but with a shallow tank as we propose above, or with your deep tank, as you propose yourself, but with sides shown in the plan fully 9 inches wide, the heat would so ascend to the thin slate above, that you would have plenty of bottom heat, but not enough of top heat to sustain your house in a suitable temperature in early forcing, and therefore the propriety of adopting some such plan as that shown in plan second, for allowing the heat accumulated directly above the slates to get into the atmosphere of the house when desirable. You may help the atmospheric temperature by keeping your tanks a foot deep as you propose, with one brick only on the sides, and then giving them water only 4 inches or 5 inches deep.

6. Again, as recommendatory of the second chamber, unless a great thickness of soil is used, neither Cucumbers nor Melons thrive when their roots come in contact with a hot slate. The second chamber will prevent all that. We should therefore make all the joints of the slate covering the tank pretty tight; and supposing that you had a chamber in both divisions, by opening your slides, and pouring in water on the slates, you could obtain a moist heat in the house; and if the floor of the upper chamber was rather open, the heated vapour would also rise among the soil, which would just suit the Cucumber and Melon too, until the latter was approaching maturity. Then in dull days you could leave the slate dry, and in very bright days you could close your slides after sprinkling the covering of the tank with a little water, to give moist vapour to the roots.

7. A more simple way to regulate all this would be, instead of a second chamber with slides, &c., to put a covering of 6 inches or 8 inches of open rubble over the slate cover, the rubble again covered with washed gravel and a fresh turf every season over that before placing in the soil. Back and front we would have narrow drain-pipes every 3 feet, standing 3 inches above the slates, and a couple of inches at least above the soil, with wooden plugs for their upper end, and through these, when necessary, we should supply moisture to the rubble, and let out heat at top, moist or dry, as might be deemed desirable.

8. Did we grow Melons and Cucumbers in the same division, we would reverse your proposed plan, and have Melons in front instead of at the back, as Melons require more sun to perfect their flavour than Cucumbers do. We have no faith in the pollen of the one affecting the fruit of the other injuriously. If any cross-breeding could take place, it would chiefly affect the seeds—the true fruit, in fact, and not the outside or eatable part of the fruit for that season.

9. We do not place much value on your iron tubes for the smoke; but if you should make them a kind of flue before entering the chimney, you will obtain much heat in the house that otherwise would get out at the chimney top, even though you used a damper most carefully.

10. Considering the position of your pit-house, the arrangement of the raised tanks is admirable; as by placing the boiler at the one corner, you walk round all your beds and stage without the least inconvenience. The great disadvantage, however, is that for such a large general house, the temperature will be nearly equal in all parts, even if you divide it into two by a partition. This will deprive the house of much of its usefulness, as you cannot force on early times, and keep bedding plants in it as you propose. Had circumstances been favourable, the boiler might have been placed in the centre, and heated one house independently of the other. Even now, if there were room enough for a passage-way above the height of the tank, the tank might be carried across in the middle at the end next the boiler, and the circulation in the first half next the boiler made complete in itself. In a cold night the slides could be removed, the others shut, and the circulation continue as now. The one half might thus be devoted to forcing, the other half to merely keeping plants safe from frost. If this could not be conveniently adopted, the first pit with its flower-stage might be shut off by a moveable longitudinal division of wood and glass, and one moveable stoppage and one moveable opening would render the circulation of that part complete. If that was too much, the division next the boiler might be so shut in, which would make a little house some 18 feet by 9 feet or 10 feet, and there, whilst all else was kept as cool as desirable, heat could be given to force flowers and plants, and to sow and bring forward Cucumber and Melon plants, so that there might be successions of them, and some good early Grapes and other fruits might be obtained from pots. In making any such arrangements, wooden sluices for openings or shuttings will answer very well, only care must be taken that the openings extend as much as possible the full width of the tank, as all out-jutting corners in the way of sluices and openings impede the circulation.

So much for this tank-house. Tank-heating seems getting into vogue. We have no right to find fault with such useful things. Had we a house of such a size to make into an *omnium gatherum*, to be used for all kinds of purposes, we would have at least two divisions, and use pipes from a boiler in the centre; at least so as we could heat a part to 60°, whilst we could keep the other at 40°. We have no doubt that the tanks will answer; and bricks, and cement, and slate, may in some places be more easily obtained than pipes.—R. F.]

INSECT IN GREENHOUSE.

I AM sadly plagued in my greenhouse with a small white fly, the name of which I know not. It takes possession of the under side of the more delicate leaves, there deposits its eggs, and burrows into the tissue of the leaf, causing it to wither up. I sponge the leaves with soap water, and occasionally fumigate with tobacco, which, to a certain extent, answers. Is there any other plan I can adopt to get rid of this pest? I enclose a leaf of an *Echites* with the deposit on the under surface.—MARY ANN.

[The little fly sent is a species of *Aleyrodes* (a genus allied to *Aphis*) which has lately become very troublesome in greenhouses, where its greater activity renders it more difficult to master than the sluggish plant-lice. We know of no better remedies than those you have already adopted, which must be persisted in regularly. The leaves most infested with the young must be picked off and burnt.—W.]

AMOUNT OF PIPING REQUIRED FOR HEATING.

Horse 40 feet by 15 feet, 10 feet at ridge, 6 feet sides, half glass. Span-roof fixed, ventilation at sides, end above door, and in brickwork level with the pipes. House divided in the middle: one end to be used as a stove, the other as a greenhouse. Required what quantity of pipes for the purpose of heating it efficiently. It is built against a stable, in which the boiler will be placed. I propose to have two flows and return in the stove, and one flow and return in the greenhouse, with stopcock at the division. I also propose to use the flue from the furnace to give bottom heat in a chambered pit in the centre of the hot-house.—H. M. K.

[You had better have ventilation also at the ridge of the roof, especially at the greenhouse part. With your flow going through the stove as you propose, two flow-pipes and one return on each side will do for the stove—that is, six pipes in all. In the greenhouse a flow and return on each side—that is, four pipes. They must be four-inch pipes.]

HYDRANGEA CULTURE.

I HAVE a large *Hydrangea*, which I have failed to bloom. The plant had general greenhouse treatment, and appeared in good health. I have cut the plant down (early in September), and placed it out of doors. The plant broke well, and I have placed it in the greenhouse with the other plants; but I am at a loss whether I ought to repot now, or not until the spring. The plant is in a twelve-inch pot, and appears to be growing well.—JOHN BLACKLOCK.

[You had better leave the plant alone without further potting. If you had still further left it alone, kept it out in the sun in such an autumn as this, neither cut down nor fresh potted, but gave no more water than just kept the leaves from flagging, and when they became yellow, kept your plant in a cool place, as a stable or a hayloft until April, then set it in the greenhouse or in a warm place out of doors, top-dressed it, and gave it plenty of manure water, we could have almost have guaranteed you plenty of bloom-buds; and when they showed you could then have removed those shoots for which there was no room, or which showed no bloom. If the buds to which you cut down were well ripened you will have plenty of bloom; if not, the bloom will be scant or none at all.]

HEATING A FORCING-PIT.

I AM about building a forcing-pit for forcing bulbs and flowers for the greenhouse during the winter months. How could I manage the flue? My present fire-hole to greenhouse is at the south-west corner of the intended forcing-house, both houses will join, both houses face direct south. I want to heat the house and heat the pit in centre. What glass would be best for roof, as my place is a bad one for the boys throwing stones? I thought of rough plate.—T. TILDESLEY.

[So far as we understand your case, there will be no difficulty in the heating. Your greenhouse, we presume, going west, and the new pit or house going east from the stove-hole. We pre-

sume, however, you mean to have a separate furnace for each. We have worked two flues from one furnace by means of dampers, but it requires some management. If your greenhouse were heated by hot water the pit might be heated by the same boiler.

Hartley's best rough plate will suit well enough, but it will require to be strong indeed to save you from boys throwing. We have little faith in the strong hand with such gentlemen; but if you got a number of the most unruly collected together, spoke to them kindly, and tell them you would be so obliged if they did not throw stones in your garden, and show them your glass, and how easily it was broken and destroyed, the boys' honour thus appealed to will seldom be appealed to in vain. If this would not do, you had better have strong wire netting over the glass, so as to avoid all heartburnings, for these unpleasantnesses there will be every time that a square is smashed. If this does not suit your case send us a rough plan of the relative positions of the two houses.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

MANURES to be got out of the framing-ground on to the vacant spaces in the kitchen garden, and immediately afterwards to be dug in. *Artichokes*, cut down any remaining dower-stalks, remove a few of the large outer leaves, and cover the roots with dry litter or old tan; it is a common practice to earth them up with the soil between the plants, but one which we entirely disapprove of. *Bet*, take up the roots carefully, and, having cleared them of leaves, preserve them in sand in the same manner as Carrots. *Broccoli*, the Cape varieties, which are now heading, must be secured from frost. *Carrots*, this crop to be taken up as soon as their leaves change; for when they continue too long in the ground they are apt to get worm-eaten, especially in rich soils. *Carblishflowers*, plant out under hand-glasses live in a patch, taking the precaution to leave room for the hand-glasses to be lifted off and placed between the patches when required. *Chives* to be taken up and replanted every two or three years. Plant them in rich common soil 1 foot apart row from row and 6 inches in the row. *Lettuces*, give air at all favourable opportunities, especially to the young plants; the Cabbage varieties intended for winter use will not need it so much. *Rhubarb*, clear away the decayed leaves, and cover the crowns of the roots with old tan or any sort of loose litter. *Savoy*, plant for the last crop. *Scorzenera* and *Salsify* to be taken up and stored away in sand.

FLOWER GARDEN.

The laying out of new grounds or improvements in old ones, which may be in contemplation, should now be proceeded with as long as we are favoured with fine open weather. It is too often the case that such operations are left till too late in the season, and are retarded by the frosts and snows of winter, thus interfering with the usual routine of labour during the busy months of spring when attention is required for other matters. Hardy creepers should be examined at this season, and all unnecessary spray removed, and their security from the blasts of winter insured. To obtain a display of spring flowers it is advisable when the flower-beds are cleared of their present inhabitants to plant them with London Pride, *Cerastium tomentosum*, Heart-ease, and *Daisies* of distinct colours, the Forget-me-not, yellow *Alyssum*, and the white *Arabis*. These are common flowers, but if each bed is planted with a distinct colour, either harmoniously or in contrast, they will have a beautiful effect. So beautiful was the effect in April and the early part of May last at Mr. Marchant's Nursery, Earle's Court, that Her Majesty, when passing, was frequently observed to loiter in her progress to admire it. Plant out *Wallflowers* and *Sweet Williams* in masses; and if in the shrubby border let them extend a yard or two in diameter; they will grow anywhere. Take advantage of the present delightful season to finish the planting of evergreen and deciduous shrubs. All large specimens of *Holly*, *Laurel*, *Yew*, *Phillyrea*, &c., should be planted now, as they will make fresh roots before winter. Have an eye to neatness, see that the borders are cleared of all dead flowers, leaves, &c., and give them a lively clean appearance by hoeing and raking. The grass edges and walks should be regularly swept while the leaves continue to fall, using the roller at intervals.

FRUIT GARDEN.

Proceed with the planting of fruit trees where it is necessary

to do so, avoiding deep and highly-matured borders; draining well from stagnant water, and planting high if the situation is naturally wet. The present time is likewise the most favourable for relifting and root-pruning such trees that are too luxuriant, and require checking to induce a fruitful habit. We would, however, prefer lifting the trees entirely (unless they are very large) to cutting off their roots as they stand. After shortening the roots in proportion to the strength of the tree spread them out near the surface, and fill in with compost on which a mulching of half-rotten dung should be spread, to prevent frost from entering the ground. If fruit-tree borders are of a more limited extent, compared with what is generally the case, the trees would be more fruitful, by which the balance between the roots and branches would be more equalised. Put in cuttings of choice Gooseberries and Currants, and make fresh plantations of Raspberries. The pruning of Pears, Plums, and Cherries may be commenced.

STOVE.

Little moisture will suffice at this season. Keep the temperature progressively on the decline, more especially in dull weather. Ventilate freely when the weather will permit.

GREENHOUSE AND CONSERVATORY.

Hyacinths and other bulbs to be procured, and potted without delay. Look sharply after mildew on soft-wooded Heaths, and dress the plant with sulphur as soon as the enemy is perceived. The Azaleas into form as soon as it can be done, to give them a neat appearance. Look sharply after red spider on Bossnias, Chorozomas, and other plants that are liable to be attacked by them. Keep Cinerarias cool and moist, and attend to repotting such as require it. Green fly to be banished by fumigation. Primulas also to be carefully attended to.

PITS AND FRAMES.

Where a few Ageratum, Heliotropes, Verbenas, and Lobelias have been kept in pots through the autumn it is unnecessary to winter young stock, as these grow so freely in heat, and are so easily propagated in spring that a few good-sized old plants, which require but little care and attention in winter, will furnish an abundance of plants by bedding-out time. When cuttings can only be procured, get in plenty at once, so as to provide against the risk of being short of stock at turning-out time. Abundance of air and light to be admitted to these structures. If any of the lights afford a partial shade to the plants from the accumulation of filth thereon, take them off and wash them thoroughly without delay. Be careful during the operation of watering to apply it to those only that require it. Remove all mouldy and decaying leaves, and keep the interior as dry as possible during dull foggy weather. W. KEANE.

DOINGS OF THE LAST WEEK.

STRANGE that with the tidings of deluges of rain, with the exception of a slight shower or two to refresh the surface, the dry weather still continues here (Luton), and farmers in some places can scarcely manage to plough or sow, though no better opportunity can be given for thoroughly cleaning the land where ploughed. The beginning of the week has been marked with all the brilliancy of a July sun, and the close warmth was even more oppressive.

FIGS.

The second crop of Figs in the house, with just a touch of fire heat have swelled off to great perfection, and I hope all will be gone before the end of the month, to let the plants have a rest in winter. The late ones in pots taken from a cold glass case into a pit, where a little extra heat can be given, are swelling nicely. Have proved that Rivers' Marselles White is a distinct sort from the common kind, being as distinguished for fertility as the other is the reverse. The finest crop of the common I saw on a wall out of doors; but though I had cuttings from it, I never was satisfied with it under glass, for though I could get some good fruit, I never could depend on getting a good dish or a basket of it at a time.

This sunny weather must help the ripening of all fruit, and the wood of fruit trees, so that we hope the next season will be better than the last and present.

KITCHEN GARDEN.

Pricked out Cauliflowers as previously stated; protected late crops of Dwarf Kidney Beans at night; gathered more Tomatoes

and Capsicums; made fresh beds of Sage struck under hand-lights, and of many other herbs, as Pennyroyal, Mints of sorts, Sorrel, Fennel, Thyme by slips, beginning to root at their base and such like, as young plants now turned out will generally stand the winter better than older plants. Earthed up the first spring Cabbages as a protection against frost. Will lay down Broccoli in a week or so; and where Cauliflowers is now coming in plentifully and faster than can be used, would recommend the stems being cut over level with, or a little below, the surface of the ground, and the leaves all removed except two or three small ones close to the head, and then the stems fixed in earth neither wet nor dry, but approaching the former—a shed dark rather than otherwise, but with the means of giving air. A dry collar would do for the purpose. The heads should be firm, not begun to open at all, and if not much more than half grown the heads should be just as close as not to touch each other. The soil or earth a little damp at the bottom of the stem will enable the stem to absorb enough of moisture to keep the head fresh; and, under such circumstances, where a suitable place can be provided for them, Cauliflowers will be kept fresh for several months, when out of doors they would be all destroyed. A little air is necessary at all times, unless when there is frost, to keep the heads from damping.

FRUIT GARDEN.

Much the same as last week, doing everything to help the ripening of the wood. Gathered, too, most of the Apples and Pears, which are now pretty well fit for housing; and even the later kinds suffer less from being gathered a few days too early, than from getting a touch of frost. If much frosted they will often keep and recover themselves better when left to lie among fallen leaves than when they are placed in store-rooms or fruit-rooms. Run the hoe again through Strawberry-rows out of doors, and though warm will give no water to Strawberry-pots until the leaves show signs of distress by flagging. This sun with a dryish soil will insure the ripening of the buds. If the leaves were allowed to flag much, there is danger that the embryo fruit-bud would be shrivelled up. Extra dryness and extra moisture are alike to be avoided now.

ORNAMENTAL-HOUSES.

See what was said last week by Mr. Keene on Orchids and store plants generally. Have cleared out the conservatory greenhouse, cut back the climbers, which look so beautiful in summer, but which would make the house dark in winter, leaving only the main shoots, and a summer sprig dangling here and there, just to give an air of lightness to the house. Washed the glass and all shelves and woodwork thoroughly. Run the paint-brush over all, to make everything sweet and clean, and in a day or two will fill with Azaleas, Camellias, Cytisuses, Epacrises, Cinerarias, Primulas, &c., the most of which are now clean as respects pots, &c., and under protection from heavy rains or boisterous winds. Potted succession Cinerarias into size 24 and 16-pots, many of the forwardest being left to bloom in 32's, where, however they will need a good deal of water.

FLOWER GARDEN.

We hardly know what to do here, as the change of the wind to the east and north presages a little frost before long, though now Scarlet Geraniums, Salvias, and, above all, the orange Cassia corymbosa, as large specimens, are as fine, may finer, than in August. We may say the same of Brugmansias planted out, which are now splendid. But a few degrees of frost injure them so much for another season, that ere long these and many other things used as high centres must be got up with the spade and the fork, and with as much roots as possible, be crammed into the smallest pot that will hold their roots, and be placed in some shady shed at first until the roots begin to move afresh. Talk of room! Why there is not one of us but would sing out for a village of room now if we saw any chance of getting it. After the 16th and 18th we hardly think it worth while to put in cuttings, except some things of great importance, and we can give them both top and bottom heat. In case frost may happen, we have taken up Golden Chain Geraniums to-day, and will follow with Flower of the Day, Bijou, Alma, and other variegated ones, placing them merely in a shed with the roots kept a little moist until we get more time to clean them, regulate them, or pot or box them. The stronger kinds after removing the leaves and softest points we will pack firmly in earth, in pots or boxes, putting them as close as possible together, and then watering them. When the water has subsided, and the surface

just begins to be dry, we will cover all the surface to the depth of an inch or two with dry soil mixed with an equal portion of charred rubbish-heap now charring, and which to prevent burning into ashes we must open and spread out to-day or to-morrow. There is no end to the uses of such a charred heap. I never have enough of it, even though I get a good many loads in a season. After this, covering the pots with dry soil, they will, in general, get no more water for the winter.—R. F.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

TRAINING PEACHES, &c., IN CORDON (*A Subscriber*).—We believe that the Rev. T. M. Pröbhart, of Richmond House, Guernsey, author of the book on cordon training, practises the method on Peach trees against his walls in the open air.

LAFAGEIRA CULTURE (*F. W.*).—If you buy our No. 555, you will find in it a full epitome of its culture.

LIQUID MANURE (*J. W. D.*).—Liquid manure is best applied to grass land by a water-cart, somewhat like that used for street-watering. The best time for applying it is in early spring. To garden crops apply it during their chief growing period. It is beneficial to all fruit trees that are not over-luxuriant. If the sewage is very rich, it will bear mixing with water.

VARIOUS (*G. L.*).—All hardy plants will live out of doors without protection. Arabis, &c. of them. Calceolarias taken up from beds are best if not cut at all. The best method to keep Geraniums is to cut down Scarlet Geraniums like Pelargoniums when they are taken up in October, and to give them two months' bottom heat of 70°, in a top heat of 50°. But all depends upon what places a man has for keeping plants throughout the year. What we know in this country, and which we would like best way for him to do; not the best way for any one else beside himself. Variegated Geraniums are more liable to misgaps in winter than plain and horsehoe kinds of equal strength.

IMPROVING GARDEN SOIL (*B. W.*).—The portion that is loamy, but exhausted, merely trench and manure with superphosphate of lime, and gas ammoniacal liquor, with sulphuric acid added. These to be added to the soil during the growing season of the crops—the trenching to be done at once. Of the clayey portion of your soil, burn a spit's depth of the entire surface, and incorporate the ashes with the soil beneath, and manure with bone dust and ammoniacal liquor. The gravelly portion of your soil trench two spades deep; sift out all the stones more than an half an inch in diameter; then cover it with 3 inches of clay from your clayey portion; and manure with half-inch bones, superphosphate of lime, and the gas ammoniacal liquor. The latter always to be given to the crop whilst growing—that is, in spring and summer.

GRAPE'S (*P. Breckinridge*).—If you are a Fellow of the Royal Horticultural Society, you can get cuttings of the rare Frontignan Grape from the Garden by the usual form of application. We do not know where else it can be obtained, as it has not been advertised in our papers. The Sarabelle Muscat is a good Grape for pot culture. It is not noticed in Dr. Hogg's "Fruit Manual," because at the time that was in preparation Sarabelle Muscat had not been sufficiently tried in this country, and its merits were not known. This and a great many more new fruits will appear in the new edition, which is in the course of preparation. La Constante Strawberry may be had of several of the trade, but we cannot recommend any particular one. Apply to those whose advertisements you find in our columns.

WORK OF GARDENERS (*B. W.*).—Buy "The Garden Manual," published at our office, price 6d. It contains all the information you say you need, as "an amateur and beginner."

GROING VINEY (*J. L.*).—If you will buy our No. 633, you will find every particular about the dimensions. It is too long to extract. You can have it for four postage stamps from our office. The only difference now is that Mr. Rivers does not dig a trench. (*W. L. L.*).—You will see our reply to the above query. The dimensions are also stated at page 55 of our last Number. (*H. S.*).—Grapes will ripen in these structures in any summer that would ripen them in a greenhouse, unless the summer and soil be wet. They have been to-ted more than one year. There is no work devoted to the stages and other fittings of greenhouses. There are some at page 393, and other pages of the first volume of McIntosh's "Book of the Garden."

SEEDLING TRIOPELEM (*B. Foster*).—The flowers not equal to many in cultivation. Even if superior we could say nothing of its worth, for this depends upon the dwarf habit of the plant.

IRRIGATION IN WINTER (*T. Jos.*).—Your gardener is quite right. The irrigation will be very beneficial to all your garden crops and trees whilst going in the spring and summer, but in winter it would sodden the roots, and render them liable to suffer by the frost.

NAMES OF FRUIT (*W. J. H.*).—It is the Downon Imperatrice. We cite again with you in feeling the want of an English name for a whole variety sent. If nurserymen were actionable for such mistakes, we should bear less of them. (*G. A.*)—The Muscat Muscadine Grape is the Chasselas Musqué.

DAISIES IN A LAWN (*J. E. S.*).—There is no way of eradication them except by having them scooped out by a knife, or scold. Two or three women we have known clear a large lawn in a few days. The bare places are so covered by the grass.

FRUIT-TREE BUDS ASKED OF DWARF FRUIT TREES (*Sally Suffield*).—Tiffany has been employed successfully for the purpose, and is certainly the cheapest and most durable material. It admits enough light.

QUICKLY-GROWING TREES (*Dorset Subscriber*).—The most eligible for your belt is the Black Poplar. We have had it grow to the height of 30 feet in seven years. Of evergreen trees, as you are not far from the sea, plant Pinus maritima. October is the best time for planting. You may give credit for the absurdly long names given to florists' flowers. "Madame Marquis d'Arilleme" given to the Verbena is superlatively absurd.

INSETS (*F. H. Law*).—The specimens enclosed are of *Julus pithehellus*, one of the Snake Millipedes. No application to the soil seems to affect them. We doubt if they attack any vegetable until it has begun to decay. If we extracted a different opinion, and were invited to rid our soil of them, we would pare off 3 inches in depth of the surface and burn it.

INSECT ON DAPHNIS (*H. B. B.*).—The insect found on Daphnis is one of the field bugs, *Capsus pabulinus*. It is not peculiarly attached to that plant.—W.

EPHORBIA JACQUINIÆ CULTURE (*B. N.*).—Do not touch your Euphorbia now; wait until it has given its beautiful flowers. Then allow the soil to get a little dry; then prune back and string a little; and then water after the buds begin to break; and fresh pot in loam, peat, or peat soil, and a little broken bricks and blue rubbish. It likes plenty of heat when growing, and plenty of sun in August and September.

NAMES OF PLANTS (*H. B. Biden*).—It is the good old Valotta purpurea. (*J. R. W.*).—Yes, it is *Lactaria dilatata*.

FLOWER SHOWS FOR 1861.

NOVEMBER 6th and 7th. ROYAL HORTICULTURAL SOCIETY. (Fruit and Chrysanthemums.) *Garden Superintendent, G. Eyles.*

NOVEMBER 12th and 13th. STROKE NEWINGTON CHRYSANTHEMUM SOCIETY. *Sec., W. T. Howe.*

NOVEMBER 14th and 15th. CRYSTAL PALACE. (Chrysanthemum Show.) *Sec., W. Houghton.*

N.B.—Secretaries of Societies intending to advertise in our columns will oblige us by sending an early intimation of their exhibition days.

POULTRY, BEE, AND HOUSEHOLD CHRONICLE.

THE MOTHER OF POULTRY SHOWS.

We could not but be amused, when passing through one of the suburbs of London, to see in a little old shop in a narrow street an announcement that Flint & Brick had begun their "Christmas club," and that the payment of a very small weekly sum would enable to participate in the distribution, during the Christmas week, of the heaps of raisins and currants, the mounds of citron and orange peel, oranges, nutmegs, and all sorts of edible temptations that were being rolled into a heap by some very black men out of such large cornucopie, all marked "Flint & Brick," that the marvel was how they moved them. It was a little shop with a descent of two steps to get into it; it was redolent of tallow and kitchen stuff; and if we were subscribers we should in claiming our prize follow out the advice of F. & B. in putting down our names, we should apply early. As we thought of this we were obliged to admit it was the real Anglo-Saxon pushing co, and those who have little to help themselves with, and nothing but themselves to depend upon, stride to the best of their ability. They every now and then, while in pursuit of those who have set the example, get near enough to them to make themselves heard, and to remind them pioneers must be in the front. The positions change at times—a forward man falls, and the gap is filled up from behind. The two classes form the history of life, and while the front point out the way to those behind, these keep the front from wavering or falling away.

In front of Somerset House every afternoon may be seen a very old horse, mounted by a very old groom, walking up and down till the clock strikes, and an old gentleman comes out; the servant touches his hat, the horse looks round, the old gentleman takes his whip and the reins, and audibly says, "Thank you, Charles," when the old groom has pulled his coat tails from under him. We know not why it should be that there is perpetual war between clerks (especially in Somerset House), and those who have to do with them in business; but it is certain it does exist. Now, no feeling of the sort could be entertained against the old gentleman in question. He had lived long enough to see how preferable it is to lessen rather than increase the troubles of fellow creatures; and as he patted the neck of his old

horse, which immediately attempted to trot, to the manifest delight of the groom, any one could feel how respectable their age made them, and every one felt disposed to admire and like them. A carefully-folded light coat or macintosh strapped across the front of the saddle spoke of olden times. All looked kindly, prosperous, and like a good balance at the bankers; the very look of the *ensemble* would have justified a stranger in cashing a heavy cheque. If on inquiry all our opinion was found to be justified, and he proved twice as good as respectable, as punctual, as opulent, as we believed him to be, he would then be among men what the Birmingham Show is among amateurs.

It is customary for the directors of railways to advertise that no applications for shares can be received after a certain day; so it is necessary there should be a last day for entering birds for competition. It is therefore our duty to remind our readers the time is come when those who mean to try for the "blue ribands" of the poultry world, should signify their intention to the Secretary. We are informed on excellent authority the entries bid fair to be unusually numerous, and that the Show will in all probability eclipse all its predecessors. We confess to a great *penchant* for this Mother of Shows; for, although if we go to the first of all poultry exhibitions, we must find it in the gardens of the Zoological Society of London, yet the first Society that was formed on a large scale, and that feared not to invest thousands without any other certain return than a show of stock during five days, was that of "Birmingham and the Midland Counties." Its originators felt they possessed the qualities that are necessary to success, and they were also aware they could persevere in the practice of them. The event has justified their confidence; and we believe they will this year meet their friends and subscribers in better circumstances than they have ever done. We heartily congratulate them on it. Their perseverance, uniform straightforwardness, painstaking, disinterestedness, and punctuality deserved no less. We conclude by reminding our friends who are exhibitors that their entries *must* now be made. We invite them to fill up their papers for that purpose, and our Number must be to them what Flint and Brick's announcement in their window was to the passers-by. We also invite all who have never seen this unique sight to go to Bingley Hall. Those who have been once are sure to go again.

TRAVELLING-BASKETS—POINTS IN SILVER SPANGLED HAMBURGH COCK.

I SHALL be obliged if you will tell me in your next Number, if the round baskets used in sending poultry to exhibitions should be made with open wicker-work at the side and canvass run through the bars, or a close wicker-work lined with canvass, and should it have a flier cover, or is the canvass considered sufficient protection?

Has a thoroughly good Silver-spangled Hamburgh cock a pure white tail with black tips, or may the feathers be slightly stained on the under side?—B.

[The baskets in which to send poultry to exhibitions should be of close wicker-work all round; they may be lined inside, but it is not necessary. If they are made very high, the top may also be of wicker-work. Double canvass is, however, sufficient protection.]

A thoroughly good Silver-spangled Hamburgh cock should have a perfectly white tail, save at the tips of the feathers, which should be mooned with black.]

FROME POULTRY SHOW.

THE Poultry Show in connection with the Frome Agricultural Society was held in a field, kindly lent for the occasion by J. Linkins, Esq., on Wednesday last; and, although in consequence of the limited classification of the prize list, and exhibitors to be residents within fifteen miles of Frome, the entries were not so numerous as on a former occasion, yet amongst them were to be found several good pens. Those most worthy of notice being Mr. R. Eling's *Game*, and but for a rule prohibiting one exhibitor taking both first and second prize in a class, there is but little doubt but this gentleman would have done so, as his pen of Black Reds were far superior to the second-prize pen; and the same rule which prevented Mr. Eling taking both the Game prizes, also prevented the Marquis of Bath making a clean sweep of the *Dorking* prizes, as his lordship

exhibited two remarkably fine pens of chickens. *Spanish* and *Silver-pencilled Hamburgs* were of inferior quality; but *Ducks* made amends, as they were both numerous and good, especially Mr. Smith's Aylesbury, and Mr. Ponting's Rovens. Miss Millward obtained first prize for *Turkeys* with a fine pair of Black. In the extra class the Marquis of Bath exhibited a fine pen of *Brahma* chickens; there was also a pretty pen of white *Bantams*. There is but little doubt that with a few alterations in their rules, &c., revision and extension of their prize list, the Frome Agricultural Society may establish a good poultry show; but like most agricultural societies, they seem to look upon the poultry department as a drag to their progress rather than as an additional attraction which they might make it, and which, in point of fact, it now is, as might have been seen by the difficulty to get to the pens during the whole day.

GAME—First (the gift of the Countess of Cork), R. Eling, Sutton Parva. Second (given by the Society), L. C. Irons, Upton Scudamore. Commended: R. Eling, Sutton Parva; F. J. Sanford.

DORKINGS—First (the gift of the Countess of Cork), Marquis of Bath Longleat. Second (given by the Society), Miss Wilcox. Commended, Mrs. Knatchbull, Badington; Marquis of Bath, Longleat.

SPANISH—First (the gift of the Countess of Cork), withheld. Second, (given by the Society), Miss Morgan, Berkley.

HAMBURGS (Silver-pencilled).—Prize (the gift of the Countess of Cork), R. Porteous, Marston.

DUCKS—First (the gift of the Countess of Cork), T. Smith, Westbury, Second (given by the Society), E. Ponting, Whatley. Commended, Mrs. Knatchbull, Badington; Marquis of Bath, Longleat.

GESE.—First, S. Giblett, Bellow Farm. Second, I. Cox, Whately. E. P. Sly. **TURKEYS**.—First, Miss J. Millward, New'om St. Lee. Second, E. P. Sly, Thonlstone. Commended, Miss L. Ponting, Whatley; C. Hatch, Marston.

EXTRA STOCK.

GAME.—Prize, R. Eling, Sutton Parva.

BRAMA POOTRA.—Prize, Marquis of Bath, Longleat.

BANTAMS.—Prize, Mr. Pickford, Frome.

Mr. George Saunders Sainbury, of Rowde, Devizes, was the Judge of poultry.

RATE OF GROWTH IN POULTRY.

"G. T." complains of the slow growth of his Dorking chickens compared with his Hamburgs. The reason is plain. The larger the bird the longer it is in attaining its growth. We some time since had a broody hen; we had no eggs we cared to put under her, but tired of her pertinacity, and pitying her for the pains she took to sit on nothing, we put under her one Pea fowl's egg, and four Cochins'. She hatched the former and two of the latter. They are now about two months old; but the Cochins are much larger than the Pea chick, and the difference becomes more marked every day. The Cochins will attain their growth in six months; the Pea fowl in ten or twelve.

THE BIRMINGHAM CATTLE AND POULTRY SHOW.

THE poultry prize lists have this year undergone a complete revision, and we are gratified to find that the changes which have been made have been perfectly satisfactory to the exhibitors. One of the most important alterations is that by which the number of hens or pullets in a pen is limited to two, instead of three as heretofore; and this new regulation may be expected to find favour with purchasers. No silver cups are offered this year by the Society, but the prizes are in several classes increased in amount, and the total sum to be competed for in this division considerably exceeds that which has been given in any former year. For instance, the prizes in the four general classes of Dorkings (Silver Grey, and other coloured Dorkings) are now in each case fixed at £5, £3, £2, and £1; and the same is the case in the two classes for Spanish fowls. The prizes for Game fowls have also been increased, and a class is opened for Brown and other Reds except Black-breasted, the latter being very properly shown separately—a change which has been made at the request of some of the leading exhibitors of these varieties. We have not space to enumerate all the alterations which have been made, but must refer exhibitors to the lists themselves. To this department of the Show we are gratified to state there have been contributed four special prizes, each of the value of five guineas, the first by Mr. Martin Billing for the best pen of Dorkings; the second by Mr. Henry Wade, of the Electric Telegraph Company, for the best pen of Cinnamon or Buff Cochins-China fowls (cock and two hens); the third by Mr.

James Cattell for the best pen of chickens of the same variety; and the fourth by Mr. G. F. Greencil for the best pen of Game fowls.

It is at present too early to form an opinion as to the extent and character of the approaching Exhibition, but it is already known that a number of breeders and feeders of stock who have not hitherto taken part in the competitions in Bingley Hall, will send stock this year, while as regards the older members of the Society we do not expect that there will be many absent. This will be the thirteenth Exhibition held in Birmingham, and it is certain that the interest felt in these useful and pleasant gatherings suffers no diminution, but seems rather to increase from year to year as the practical objects which the Council seek to promote become more distinctly apparent.—(*Midland Counties Herald*.)

TUMBLING PIGEONS.

No doubt the readers of your Journal may remember the accounts given by Mr. Paton and "HANDY ANDY" some time back, respecting the Scotch House and Air Tumblers and the Birmingham Rollers. The statements then published of the excessive tumbling of those birds greatly astonished me, and I was much delighted to accept some of the varieties above mentioned, and was surprised to find that those statements were not at all exaggerated. As I have bred several pairs of these birds, I thought an account of their mode of tumbling might interest some of your readers. I enclose you the following remarks:—

The Birmingham Rollers, or at least those I had sent me, are coarse, common-looking birds of various patchy colours, mostly like a very foul-feathered Baldhead, and that seems to be generally red, or as it is termed, a "red badge." Their eyes seem to be as often "bull" or "mud" coloured, as they are pearl; the feet unfeathered, and the beaks long—altogether a very mongrel-looking set. But we must not always judge by appearance. At first sight I really thought the birds had been changed—they could not be Tumblers; but when once they were let out there was no mistake. Their tumbling is extraordinary. Every few seconds over they go, one, two, or three summersaults at a time. Here and there a bird gives a very quick and rapid spin, revolving like a wheel, though they sometimes lose their balance, and make a rather ungraceful fall, in which they occasionally hurt themselves by striking some object. I manage to make most of mine fly for an hour a-day, but their excessive tumbling fatigues them much.

The House and Air Tumblers are a Scotch variety. I do not know if they are descended from the Indian Ground Tumblers; but certainly some of them are scarcely able to fly on account of their excessive tumbling.

In comparison to the Short-face Tumblers they are certainly coarse in appearance; yet they have all the features of common Tumblers, and their eyes are mostly pearl. In plumage they are very various; many whole-coloured, some pretty good mottles, but mostly red, with a few white feathers.

In tumbling there is much diversity of style. They generally begin almost as soon as they can well fly; at three months old they tumble well, but still fly strong; at five or six months they tumble excessively; and in the second year they mostly give up flying on account of their tumbling so much, and so close to the ground. Some fly round with the flight, throwing a clean summersault every few yards, till they are obliged to settle from giddiness and exhaustion. These are called Air Tumblers, and they commonly throw from twenty to thirty summersaults in a minute, each clear and clean. I have one red cock that I have on two or three occasions timed by my watch, and counted forty summersaults in the minute. Others tumble differently. At first they throw a single summersault; then it is doubled till it becomes a continuous roll, which puts an end to flying, for if they fly a few yards over they go, and roll till they reach the ground. Thus I had one kill herself, and another broke his leg. Many of them turn over only a few inches from the ground, and will tumble two or three times in flying across their loft. These are called House Tumblers, from tumbling in the house.

I have a pretty good flight of young ones still capable of flying their hour daily, of which in a few months' time few will be safe to trust out on a windy day. When on the earth they often make many unsuccessful attempts to reach the roof. Owing to their tumbling over the act seems to be one over which

they have no control—an involuntary movement which they seem to try to prevent; as I have seen a bird sometimes in his struggles fly a yard or two straight upwards, the impulse forcing him backwards while he struggles to go forwards. I suddenly started, or in a strange place, they seem less able to fly than if quiet in their accustomed loft.—B. P. BRENT, *Dollington, Sussex*.

COCHINS-CHINAS AT WORCESTER SHOW.—The pen of Cochins with which Mr. Tudman took the first prize at Worcester, were not (as stated in our report) claimed by Mr. Tudman at the Crystal Palace in August last.

ASTHMATIC CANARY.

SOAK some bread in hot water, then squeeze and drain the water off and pour a little milk on, then also drain off, and then give this soft bread to the bird, and let him eat as much as he will for a week or fortnight, and at the same time, or every third day, for a change, give him some bread-crumbs (dry), and some yolk of an egg chopped fine; grounds-l, of course, or lettuce or water-cress, and cleaned and gravelled daily. With this treatment the bird will be well and singing in fourteen days, and, if not singing, rapidly improving. The writer has had two valuable birds also songless nearly twelve months, and this treatment in six days has already brought one to sing, and the other is improved.—T. C. H.

IS THE FEMALE BOMBUS FERTILISED IN THE AIR?

WOULD Col. Newman, who has so carefully attended to the habits of humble bees, have the kindness to state whether the queen humble bees are fertilised in the air or on the ground? I have a special reason for wishing to know this little fact, and whether the fertilisation does not often take place as late as in September?—C. DARWIN.

[The queens or females of the humble bees are not fertilised in the air, and the act of fertilisation takes place either in the nest or on some flower, or on the ground.]

I have made observations, more or less, since the year 1798, and give the result—scarcely half a dozen instances in sixty years.

1st. I have seen one couple come out of the nest of the *Bombus terrestris*; these flew away instantly, and were united until I lost sight of them.

2nd. I observed one male and a female come out of the nest of the *Bombus lucorum*, they separated near the entrance of the nest in the earth. The male was unable to fly, I examined him and found evident signs of recent connection.

3rd. The best view I ever had was at Upton Hall, in Northamptonshire, where I saw a male come to a young queen which was busy on a flower; they elung together, and went about 10 yards to another flower, and I watched these for about ten minutes until they separated; the male continued united during their flight, and both used their wings apparently with great ease.

4th. I saw a couple of the *B. hortorum* on a flower, and watched them until they separated; they took one flight and separated in about seven minutes from the time I saw them first. All these cases were in the month of August.

5th. The next case was of the *B. muscorum*. I watched a male of the *B. muscorum* among some long grass—at first I thought it was coming out or going into its nest, but on going very near I observed the bee alight near a young female of the same species, and after showing signs of kindness they flew off in union, but so rapidly that I could not follow to observe them again; this last was about the first week in September. The *B. muscorum* is the latest in appearing and the latest in nidification. I have seen nests of the *B. muscorum* as late as the last week in August, when the combs contained unhatched drones; and the latter almost always hatched before the young queens.

WASPS.—I have never except once observed the fertilisation of the wasp near Thornbury. On the 7th of September, 1847, I was walking with my bailiff, Mr. Cossam, of Thornbury, when we saw a curious long-looking insect about 20 feet in the air; on its coming very near (it was gradually descending) it proved to be a male and female wasp united. Each of the wasps was trying to fly in a different direction. They fell to the

ground, and I immediately crushed them both so as to kill them, but not to mutilate them at all. I had them carefully packed and sent to the Committee of the Entomological Society, in London, directed to their Secretary; but as ill luck would have it, the box was intercepted by some letter-carrier or other person, and never reached its destination. The queen was more than double the size of the male.—H. W. NEWMAN, *late Lieut.-Col. (Commandant) the South Gloucester Militia, Hill-side, Cheltenham.*

N.B.—In late seasons such as 1816 and 1860, and in a few springs such as May, 1837-1838, I have noticed nearly one month difference in the hatching of the drones or male Bombs, and I have no hesitation in saying that the fertilising of the young queens, particularly of the *B. muscorum* may be retarded until the second week in September.

DRONE INFLUENCE.

WHILST driving a condemned stock of bees to-day (Oct. 9th), I found very many of them well-marked Ligurians. The hive contained a second swarm, and was one of four stocks and swarms standing at a distance of a mile and a half from my apiary, which is, as far as I know, the only apiary in the county of Devon containing Ligurian drones. There is, therefore, no doubt that the queen has been hybridised by one of my drones, and it is my intention to present her to "A DEVONSHIRE BEE-KEEPER," who will I hope report her adventures in due course to the readers of THE JOURNAL OF HORTICULTURE.—A DEVONSHIRE BEE-KEEPER.

PARTHENOGENESIS IN THE HONEY BEE.

THE account of the investigations of the German naturalists, and the wonderful revelations of the microscope so kindly furnished by the "DEVONSHIRE BEE-KEEPER," may well seem to establish the fact of true parthenogenesis in the honey bee; yet there is a feeling of regret that the opportunity afforded of applying the test was lost by removing the queen whose wings were undeveloped. I may appear prejudiced or sceptical when I say that surely she would, impelled by her instinct about the fourth day of her age, have sought the open air, traversed the alighting-board, and fallen to the ground never to rise again. Such was the fate of a young queen in one of my hives, one of whose wings was imperfect, and which I supposed had been mutilated in the struggle for pre-eminence. On the other hand, it may be argued, if the wings are naturally defective when the insect is hatched, such is the extreme delicacy in the organisation of the queen bee, that her instinct might be impaired in a corresponding degree.

It is, however, quite certain that queens which produce the eggs of drones only are usually found in external appearance to be quite perfect. A queen has been known to exist many months without laying any eggs whatever, and, it was supposed, would have remained sterile. Such an instance occurred in the apiary of a very intelligent and experienced bee-keeper, whose bees enjoyed the advantages of the heather, and were in consequence in full activity late in autumn. Perhaps a solitary instance such as this may be regarded rather as the exception which proves the rule, or it may possibly point to some hidden truth.

That fecundation is sometimes repeated was not overlooked by Huber, though he alludes to it only in a casual manner. I once found it occur in my apiary. A queen which I had reared artificially in August was fecundated on the ninth day.* Forty-eight hours afterwards, when I was congratulating myself on the reduced numbers of the colony being about to be replenished, I was not a little surprised to see the queen again leave the hive. She continued her excursions four days, and then returned fecundated.

I believe few bee-keepers are aware of the frequency of these excursions. With it is queen it was very remarkable. As I have not my notes to refer to I cannot be certain of the exact number of times she left the hive, but it was more than thirty. The weather was favourable, and drones had become scarce. She was of small size, and I did not remark that she became much distended during this period, and she proved an excellent queen. I have sometimes observed the workers worry at the drones while the queen was still going out; but they did not

appear to disable them, only to give a rough hint that it was only by suffering for a little while that they were allowed to live at ease, or I thought perhaps some of the drones were becoming old and feeble. I should like to know if the drones of the defective queen were destroyed or only bullied, also the age of the queen when she was removed.

How valuable the Ligurians will be for making experiments! but how impossible to sacrifice such treasures! The rising of artificial queens and forming artificial swarms are sad impediments to the ordinary labours of the hive, and it fills one with wonder to hear of the fruit of their labours. Is it to be understood that the ten families which have proceeded from one stock are sufficiently strong to be reserved over the winter? I presume they have been furnished with combs and supplied with food.—INVESTIGATOR.

THE QUEEN BEE.

A VIRGIN QUEEN CAN UNDOUBTEDLY BREED DRONES.

WHEN I wrote the reply to "INVESTIGATOR," which appeared in THE JOURNAL OF HORTICULTURE of the 17th ult., I was only able to describe the difference which was apparent to the naked eye between the spermatheca or seminal reservoir of a virgin, and that of an impregnated queen bee. Since that time I am indebted to the skill and kindness of Mr. J. U. Huxley, the talented house surgeon of the Devon and Exeter Hospital, for the opportunity of verifying and confirming, by means of the microscope, some of the statements made by Siebold, the distinguished German naturalist, and ultimately of establishing beyond question the fact that a drone-breeding queen is a virgin queen.

Mr. Huxley first dissected out and then punctured the spermatheca of a fertile queen, and having extravasated some portion of its contents placed it under the microscope. It immediately became evident that the spermatheca contained countless thousands of lively spermatozoa, consisting of slender filaments which rotated, turned, and twisted with inconceivable rapidity. For some time the movements and contortions of this animated mass of delicate filaments were so amazingly swift, that we found it impossible for the eye so to separate a single spermatozoon from its fellows, as to follow its movements or to detect either of its ends, which gradually tapered off to such an extreme degree of fineness that it appeared almost impossible to detect where it either began or ended. After the lapse of from a quarter to half an hour the rapidity of their movements was so far diminished that we were able to perceive that these spermatozoa consisted of thread-like filaments tapering at both ends and entirely unconnected with each other.

The next proceeding was to dissect out the vesiculae seminales, or seminal receptacles of a drone, and having punctured one of these and submitted its contents to examination in the microscope, we were soon able to detect the presence of similar spermatozoa to those found in the queen, thus proving beyond all question the identity of the contents of the spermatheca of an impregnated queen bee with the semen of the drone.

At this point our investigation must have terminated, but for the unhesitating kindness of Mr. J. E. Briscoe, of Abington, near Wolverhampton, who on the 12th inst. forwarded to me by post a living queen which had never laid any but drone eggs, with a request that I would ascertain by dissection whether she still remained a virgin. Here, then, was the very thing which we required, and it will readily be imagined with what cautious eagerness I dissected out the spermatheca preparatory to submitting its contents to the test of the microscope. The result was exactly what I anticipated. The contents of the spermatheca turned out to be a limpid, colourless fluid as clear as crystal, and in which the highest microscopic power failed to detect the faintest trace of those lively spermatozoa which were found in such countless multitudes in an impregnated queen.

These investigations establish the fact that a virgin queen is capable of laying eggs which will hatch into drones, and place the correctness of Dzierzon's theory beyond cavil. In order that no link in the chain of evidence may be wanting, I append the history of the drone-breeding queen in Mr. Briscoe's own words.—A DEVONSHIRE BEE-KEEPER.

* Wolverhampton, October 16th, 1861.

† Dear Sir,—I will briefly give the history of the queen I sent you from my book of memoranda taken at the time:—

‡ June 15.—6.30 A.M., removed queen from box No. 4.

* After an absence of fifty-eight minutes.

"June 29.—Heard hoarse piping, the eldest of the young queens not having obtained her life."

"July 30.—Shrill piping commenced.

"July 1.—No. 4 swarmed at 10 A.M. In the evening joined part of the swarm to another swarm hived on the 20th of June, box No. 3, and having captured one queen, put her with a small quantity of bees, perhaps three pints, into a wicker-hive, of the dimensions recommended in "The Honey Bee," by Dr. Bevan.

"Next morning I caught a second queen, which had also come off with the swarm on the 1st, but had remained with a cluster of bees under the floor-board of No. 3, after the bulk of the bees had entered the box. This queen I also put into the wicker-hive, being apparently a larger and stronger insect than the one first captured. One of these queens (the smaller one I believe) was cast out the same evening. The survivor is the one I forwarded you for examination, and I account for her virginity in the following way:—

"Firstly. The weather was for more than a month very unsettled.
"Secondly. The number of bees was small, and on account of the bad weather made comb very slowly, so that they never occupied more than one side of the hive, and the comb even on that side has never been brought to within 5 inches or 6 inches of the bottom.

"Thirdly. The passage out of the hive is very narrow, although quite sufficient to allow free ingress and egress for the workers.

"The queen did not lay any eggs until the beginning of August, when I commenced to feed the hive, and I soon suspected (what turned out to be the case)—*i. e.*, that she was only laying drone eggs, as the bees prolonged the cells (all workers cells) beyond the level of the comb. At the same time she did not lay with the same uniform regularity as an impregnated queen, but deposited her eggs in somewhat isolated groups. Her wings were perfect as she led out the swarm, and two of her sister queens—*i. e.*, the one left in the old hive, No. 4, and another I caught and put into an ordinary wicker-hive, were fully impregnated.

"I never saw the doctrine of parthenogenesis advocated until I read your able article in THE JOURNAL OF HORTICULTURE, on the subject which seemed so strongly supported by such irresistible evidence that it at once convinced me of the truth of the theory. Had I possessed the information sooner in the season I should certainly have endeavoured to raise young queens from my Ligurian stock to put at the heads of my other hives, for the purpose of increasing the chance of genuine impregnation of the young Italian queens next season, which, as the Italian hive contained scarcely any drones, could have little chance of being accomplished this season.

"Yours very truly,

"J. E. DRISCOLL."

UNITING BEES.

YOUR correspondent "A. W.'s" surprise, at page 38, as to what would result from the juncture of his old Ligurian stock and swarm, is much nearer the mark than the reply, which, surely, must be some slip of the pen.

Any one at all acquainted with the storifying system knows full well the strong predilection bees have at the approach of cool weather to ascend, not descend. Should the hive containing the swarm be filled with combs, and anything like the same store as in the box, which we presume is fitted with bars affording a free passage upwards, ascend they will undoubtedly, hatching out any brood and exhausting the store below, their practice being to use the lower honey first. The box can be removed when empty, and, seemingly of an unserviceable size, had better be condemned, the comb cut out to fit the frames of a well-proportioned hive, into which your correspondent's first Ligurian swarm next season might be introduced with telling effect. In joining bees I always like to keep the queen I wish to save in the upper box, should one queen be previously perceived it should be the lower. It would lessen the risk of fighting the joining taking place at dusk, aided with a good puffing of tobacco smoke to both.

Such a case as "A. W." puts I had last season. A weak colony in a straw hive topped with bars and slides (described in No. 4); another in a Stewarton-box, also weak, I put the two together, the box uppermost, drawing the slides gently; all went right, the smoke keeping down any attempt at quarrelling. Midwinter, in my absence from home, another such flat-straw hive (having been temporarily removed from its stand to facilitate the training of a fruit tree on the wall behind), was unfortunately overturned, and lay on one side on the border during a dreadfully wet and stormy night. On my return, there was a case—combs soft and down, all in a mess; the bees providentially safe, from having ascended to the upper side, seemingly at the outset; their queen, the most prolific I have ever seen. She, with her subjects, I was most wishful to preserve; but how to do it—there was the rub. Recollecting the under hive of the united bees must be by this time reared, I looked and found it so; not a bee but was packed in the box above—I, therefore, cautiously slipped it out, placing a four-inch octagon cke in its stead; then at the middle of the day, with the assistance of a couple of turkey feathers, moved, without casualty, the fallen bees therein, fed, and saved them.

I may revert to uniting generally at a future time. I have joined five colonies this season, all the dead bees seen were three,

two workers and one of the united queens, round whose royal remains, about a dozen workers were grouped, solemnly musing on this monument of fallen greatness.

Some of your correspondents' killing tales in this way are woful to contemplate.—A RENFREWVILLE BEE-KEEPER.

A LIGURIAN MISADVENTURE.

"I RECEIVED the stock of Ligurian bees last Monday about 1.30 P.M. They appeared alarmed, and made a great noise all the afternoon. At 3.30 I began driving a weak stock I had bought on purpose to unite with the Ligurians. It was nearly an hour before I could get sufficient bees in the upper hive to feed the queen was there. I put the driven bees out of the way after carefully closing the entrance so that none could escape; turned up the old straw hive, and closed it also. I now very carefully loosened the zinc cover over the Ligurians, but did not remove it, and here my assistant (a lady) found out that the Ligurian could sting through perforated zinc. Now, also, began my troubles. I found two combs broken loose. I then opened four slides of a bar-and-slide hive, and after removing very carefully the bottom piece of zinc in your box (not a bee escaping or being hurt) I took off the top piece of zinc and removed the loose combs, brushing off the bees with a feather; took out the two bars and combs, brushing off the bees, which descended rapidly into the bar-and-slide hive; took off your box, and after giving a few puffs of fungus smoke into the bar-hive, and the same into the straw hive, put the straw hive on the top of the bar-hive, and drew the slides. I could hear there was some fighting, and the noise your bees made when their arrival was continued all night. On Tuesday morning I feared loss of queen, the bees flying about very wild; 11 to 12 o'clock I lifted up the straw hive, cut out the comb, and swept out the bees on to the bar-hive and through the slides. The uproar continued just the same, and at half-past 4 P.M. I removed the bottom board and swept away the slain into a corner of the room. The confusion from 3 o'clock I think had increased. My assistant searched the heap of dead bees and found the queen I enclose. I then took up the driven stock which had remained closed, and, opening the slides, suddenly shook them on to the top of the bar-hive, and put the honey-box over all. Still the uproar continued, and I was fairly at a loss to account for it, when my assistant said, 'Here are a few bees on the floor, I will sweep them into a tumbler, and you can put them into the hive.' This was done several times from the same spot in the course of the next ten to fifteen minutes, when to my astonishment I saw a queen, and put her very carefully into the hive. In the next fifteen minutes there was hardly a bee to be seen, and all was quiet, no more fighting or uproar, and since that time the bees have eaten 7 lbs. of sugar made into syrup by just boiling 2 lbs. of sugar in one quart of water, and then adding a large spoonful of honey while the syrup was hot. They are fed with a bottle.

"Now, Sir, I have no doubt but that the Ligurian queen is in the letter I send. My assistant has been reading page 452 of THE COTTAGE GARDENER, and hopes, that, like S. Anely, it may be mistaken; but she cannot give any reason for such hopes; so to make her mind easy, will you please say if you think the enclosed dead queen is the Ligurian or not? I cannot possibly see how it could be the other.

"The Ligurians are a much prettier bee, and we think more active in their movements; at all events, they are favourites, and although I have failed now, I hope next spring to have either a queen or a stock to try again with.

"My bees are all in-doors. This hive has been put to the north, and is in a closet up-stairs leading out of a bedroom. Their passage out being under a window-frame. They are now hard at work. I saw above a dozen tale in pollen to-day in the course of half an hour, and there is great heat inside the hive. I shall now feed slowly, but as the season for breeding is over, I shall not be able to say if it is the Ligurian or common queen in the hive. I put in six very large sheets of old comb, and I see they have made a good deal of new comb in addition."—J. N.

[I regret to say that the dead queen mentioned in the foregoing letter was undoubtedly the Ligurian. My correspondent made a great mistake in attempting to unite bees to his Ligurian stock so soon after its arrival. The Italians should have been set at liberty, and the excitement produced by travelling allowed to subside before they were introduced to strangers.—A DEVONSHIRE BEE-KEEPER.]

THE PROFIT OF BEE-KEEPING.

SOME years ago a bishop was holding his first visitation of the clergy, of his diocese in a town in one of the inland counties. Amongst those assembled he soon discovered an old college acquaintance whom he had not seen for a great number of years, but whom he greeted with all the warmth of a renewed friendship. On comparing notes with his friend, the bishop learned with regret that he was still a curate in a country village at a stipend of £100 a-year, and that he had a wife and large family to support. The worthy curate, however, invited the bishop to spend a day with him before he left the neighbourhood, and the latter, not wishing to appear proud, accepted the invitation. On reaching the parsonage he was surprised to find his friend's wife an elegant well-dressed lady, who received him without any of the embarrassment which a paucity of means too frequently occasions in those who feels its pressure. The children, too, were all well dressed, and looked anything rather than as having suffered from the pinching pains of unappased hunger. But the good bishop's astonishment was still greater when he sat down to partake of a repast worthy of the traditional and customary fare of his order, and was invited to "take wine" of the purest flavour and aroma with his fair and graceful hostess. Knowing that his friend was originally a poor man, he considered that he must have received a fortune with his wife. After, therefore, the latter and the children had withdrawn, the bishop introduced the subject, by expressing a fear that his friend had gone to an unusual and injurious expense to entertain him, and that it would entail privation upon him afterwards. "Not at all," replied the curate, "I can well afford to entertain an old friend once in a while without any inconvenience." "Then," rejoined the bishop, "I must congratulate you, I suppose, on having received a fortune with your good lady." "You are wrong, again, my lord," replied the poor curate; "I had not a shilling with my wife." More mystified than ever, the bishop resumed. "Then how is it possible for you to have those comforts around you that I see, out of a hundred a-year?" "Oh, my lord, as to that, I am a large manufacturer as well as a clergyman, and employ many thousands of operatives, which bring me in an excellent living. If you will walk with me to the back of the premises I will show you them at work." He accordingly took him into the garden, at the back of the house, and there was a splendid apiary, with a large number of beehives, the source of the curate's prosperity. The bishop never forgot the circumstance, nor did he ever fail to make use of its argument; for when he afterward heard some poor curate complain of the scantiness of his income, he would cut the matter short by exclaiming, "There, there, let's have no grumbling. Keep bees, like Mr. —; keep bees, keep bees!"—(*Mark Lane Express.*)

REMARKABLE PRODUCE OF HONEY.

MRS. PARKER, of Station Street, Lewes, who has kept bees for years, and during 1860 was very unfortunate (out of three hives only saving 6 lbs. of honey, and three sets of bees), has now had the wonderful produce of 76 lbs. of honey from one hive. This is the more remarkable, as bees generally have been so very unproductive this year. They were fed all the winter upon sugar and honey.

THE RABBIT (*LEPUS CUNICULUS*): ITS HISTORY, VARIETIES, AND MANAGEMENT.

(Continued from page 490.)

FEEDING RABBITS.

THE success of breeding Rabbits on a large, or even on a small scale, depends in a great measure on the care taken to keep them healthy—a state indispensable to all animals reduced to a state of domesticity. These cases are the more easily understood, as this state of confinement completely annihilates many of the instincts of self-preservation with which Nature has endowed the animal.

Rabbits are herbivorous, and the plants, grains, and fruits that may enter into the composition of Rabbits' rations are as numerous as they are varied. All kinds of vegetables—as carrots, parsnips, beetroot, artichokes, cabbage, endive, celery, potatoes boiled or roasted, lettuces when old and run to seed are best,

saintfoin, lucerne, lentils, vetches, pea and bean haulm stored for winter, chicory, marsh mallows, sow or milk thistles, here parsley, and dandelion, wild or creeping thyme, pimpermel, aniseed, coriander, and pepperment when green, and fennel, constitute a tonic and strengthening forage, which also please the animals but must be given sparingly, being very exciting food.

All plants, &c., obtained by the weeding of gardens, omitting the mustard plant and poppy. Among fruits desirable, are apples, pears, acorns, beech nuts, &c. The leaves and cuttings of all trees. All the above-mentioned vegetation may daily contribute to the food for an animal that will take almost any plant or vegetable if it is administered properly and seasoned with drier food.

Of the dry substances which form the staple food for Rabbits, oats and barley are the principal. Buckwheat bruised is much used on the continent, but I have never tried it myself. All kinds of meal will be found good for them—viz., barleymeal, oatmeal, middlings, fine and coarse, pollard, and bran. But the great object is to give them as much nutriment in as small a quantity of food as possible: therefore, the finer qualities of meal is the cheapest food, and must be mixed with water to a stiff mash and given to them warm. Barleymeal, oatmeal, or middlings, mixed with boiled potatoes is very nutritious and fattening. Grey peas soaked in water till they sprout is one of the most fattening of foods that can be given. One handful a-day to a full-grown Rabbit is sufficient, and two meals of other food will fatten a Rabbit in a very short time. Linsed boiled very slowly for about two hours and mixed with any kind of meal, is the best food to restore a lean or an emaciated Rabbit to condition, and it also imparts a sleek appearance to their coats.

TIMES OF FEEDING.

In the morning at daybreak, and from eleven in the morning till one in the afternoon, and one hour before sunset, the Rabbit leaves its burrow to seek its food.

The tame Rabbit although not born in the warren retains the same instinct, and it is at the same hours that you see him awake and looking about, almost asking for its food.

GIVING GREEN FOOD.

If dry forage is given them indiscriminately at stated times, you must not do the same by green stuffs. They should never be given when damp with dew or rain, because this wet food tends to cause meteorisation or swelling of the belly, and almost always causes diarrhoea, which makes them thin and more often kills them. These diarrhoeas are owing to the intestinal irritations, which it is the greatest importance to prevent. During long rains the plants should be gathered the day before they are to be given them, and by exposing them to the air to facilitate the evaporation of the water. You contribute to this evaporation by spreading the greens in thin layers, or placing them on a hurdle. If these means will not suffice, you should mix with some straw which absorbs the damp. If you mix them with hay, which is still better, it produces the same effect, and the mixture serves for rations. At the same time it is necessary to avoid giving them greens that have been picked some days, and through laying together become fermented, as they would hurt the Rabbits seriously.

INCONVENIENCE OF CONTINUAL GREEN FOOD.

A too-watery green food given continually, and particularly if the sorts are not varied, is attended by grave inconvenience; the belly of the Rabbit grows big, its stomach is unusually enlarged, its flesh becomes soft, it becomes idle, lymphatic, and is often attacked by the tape worm which is developed in strings round the intestines. It has often a liquid goitre, and often dropsy show themselves. As we have before said, the wild Rabbit lives on green food and yet is vigorous; but we must remark, that he has a choice of food, not merely watery green food, but tonic herbs, and that by instinct it selects those plants that are tonic and strengthening. It has, moreover, the possibility of exercise, which contributes to its health.

CHANGE OF FOOD.

Like all other animals, change of food is necessary—it excites their appetites and assists digestion. This change is more necessary in the sedentaries—that is to say, those shut up in hutches, than those having the privilege of exercise.

CONDIMENTS.

The greater the impossibility to change the green food, the greater the necessity for seasoning it. This may comprise green plants—such as parsley, fennel, coriander, aniseed, peppermint, bitter chicory, wild thyme, pimpernel, &c. These plants should be cultivated for this, and twice a-week these plants should be mixed with other green food. Salt as a seasoning should be mixed with meal one or twice a-week.

Some Rabbits eat faster and require more food than others of the same size and age. As a general rule it is sufficient to give them just what they will eat at the meal, and it would be better they left off hungry than they should leave their food and waste it. It sometimes happens that Rabbits refuse food, and you find the portions that you last gave scarcely touched. The common opinion is, that if a Rabbit breathes on his food he will not touch it after; but this is an error, for if you take that away and give fresh the result is the same. The true cause is a loss of appetite caused by cold or a derangement of the digestive organs. The quickest way to cure them is, to give a slice of bread dipped in warm milk, not more than the bread will soak up, and not too warm. This with a nice warm berth and a good bedding of hay will restore the appetites of Rabbits to their ordinary food.

GENERAL RULE.

Give chiefly dry food, and always let there be a vessel of clean fresh water, from which they can drink whenever they please. This is contrary to the usual custom; but from experience we can state that it is conducive to the health of Rabbits.

FATTENING RABBITS.

Many ways of fattening Rabbits have been recommended. Nothing answers better than barley-meal, oatmeal, soaked grey peas, boiled linseed mixed with meal; but these substances must be varied. Oil-cake will fatten Rabbits to a great size, but the difficulty is to get them to take it, which is only done by starving them into it, and by giving very little at first, which should be pounded and mixed with meal; the cake should be placed near the fire, and, when warm, can be pounded easily. Many writers have asserted that if you give green food while fattening Rabbits it will defeat the object. I do not advise a large quantity of green food, neither do I advise it to be of a too watery kind, as cabbage, &c.; but a very little good aromatic food, as dandelion, thistles, or any plant of the same family. When these plants cannot be got, I would advise a little water given once a-day, or to accelerate the process of fattening a little oil sweetened with sugar. I was once shown a Rabbit of 14 lbs. weight that had been fattened solely on clover hay and milk sweetened with sugar, as much as it liked to drink. I have also seen Rabbits killed in first-class condition that had been bred, reared, and fed in a strawyard and shared with the cattle, only having green food, hay, straw, &c. The best age at which you can take Rabbits to fatten them is from four to six months; having reached that age they fatten on little, while before they would not fatten, having nothing but skin on their bones in consequence of their growth. One should not wonder to see them get thin when they are young; one should rather be uneasy if they grew too fat, it being an unnatural state, and prognosticating a small, stunted Rabbit.

Rabbits should be kept at all times in clean airy habitations, and you must pay attention to those you fatten. Although much exercise is not good for them at this time, if they were placed for a few hours a-day, in fine weather, on a piece of dry gravelly ground, and given a little green food to eat, it would greatly contribute to their health. In selecting your subjects for fattening, the young males should always be sacrificed before the females, they become amorous sooner, and their flesh always loses some of its flavour.—R. S. S.

(To be continued.)

GESTATION OF GUINEA PIGS.

IN THE COTTAGE GARDENER of January 22nd, 1861, under notice "To Correspondents," it was stated in reference to Guinea Pigs, that "the doe breeds when two months old, and has from ten to fourteen young one in one litter several times a-year, after a gestation of three weeks."

In the following Number I expressed my astonishment at such statements, and in reply to which appeared the following note:—

"The number of their litters, and the period of gestation are very powerfully influenced by the temperature in which the Guinea Pigs are kept. If their litters is in a heated room, such as a stove or warm greenhouse, they multiply most rapidly, and at a much earlier age than if kept in a cold out-house."

This discussion having attracted the notice of Mr. Darwin, he wished me try the experiment, as he did not think that warmth could cause any such difference in the period of gestation.

The following is the result of my first experiment, having received five Guinea Pigs, one hour and three sows:—

The first sow was placed in a hutch out-of-doors at the north side of the house, exposed to all weather, and where not a ray of sunshine could be felt. She went to the bear on Saturday afternoon, May 25th, and 1 b. brought forth four young ones on Sunday morning, August 1st. Period of gestation being ten weeks and a few hours.

The second sow was placed in a hutch and kept in the kitchen chimney-corner, where all the cooking, &c., was done, and the fire scarcely went out at night. Her hutch was littered some inches thick with chaff, and she laid basking in the warmth apparently much enjoying it. She went to the bear on Thursday afternoon, June 13th, 1861, but she died on the evening of Thursday, the 8th of August, apparently of disease of the heart most likely brought on by the heat. A post-mortem examination showed her to contain five young ones nearly full grown, and as she had already completed eight weeks of her gestation, this must quite disprove the three weeks' statement.

The third sow was allowed to remain loose in the pigeon-loft. She had a comfortable, warm-sheltered lodging, the weather being also warm, but no artificial heat was applied. She went to the bear on Wednesday afternoon, July 31st, 1861, and littered on Monday morning, October 7th. Her period of gestation being nine weeks and a little over four days. She had five young ones, two were dead, and the three living rather small. Her period of gestation being only between two and three days shorter than the first sow's, a variation of no particular amount.

I should like to hear if any other of your readers have tried the same or similar experiments. If I have an opportunity I will try one by the kitchen fire, and the other out of doors in the cold this winter, and report the result in due time.

I am sure you desire to be as correct as possible in all your statements, and, therefore, need not apologise for troubling you with these particulars.—B. P. BRENT.

[We are especially obliged by such communications as the foregoing. If journalists were incorporated, they ought to have as their motto—"Truth above all things."—Eps. J. of H.]

OUR LETER BOX

BOTTLE-FEEDERS FOR BILLS (A *New Hazard*).—Messes, Neighbour & Son's will gladly exchange the unfortunate float-feeder which was sent in mistake. They have now an ample supply of bottle-feeders in both their establishments.

TAMING A HORSE—VINEGAR PLANT.—*Cherica* inquires—"Could any of your readers advise me how to tame a very shy horse in the stable, and how to teach him to stand? He will not bear being haltered or otherwise fastened by the head when I stop at cottage doors and have to leave him outside. Could I obtain a vinegar plant as where?"

FOOD FOR A COW (H. H. James).—If she is to be kept on grass and hay only, three acres will not be so much. But that space would keep two cows, if half an acre were pasture; half an acre and eight rods wheat; one quarter of an acre oats; and the remainder for green food, such as early rye, tares, cabbrages, clover, mangold-wurtzel, and Italian rye grass. But this requires good stable husbandry and very-sant cropping, which is easily effected by the aid of a good supply of liquid manure. We do not know the average produce per acre of wheat in Surrey; but of all England it is about three quarters, and of straw 26 cwt. A bushel of wheat weighing 48 lbs. yields 45 lbs. of flour.

LONDON MARKETS.—OCTOBER 21.

POULTRY.

There is a slight increase in the value of Poultry. Trade is somewhat improved, and the supply is small. Fattridges are becoming scarcer, and are in great demand. At the south they were to be cold, we think the ordinary prices of this season of the year would be more than maintained.

METEOLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 54.1° and 37.5° respectively. The greatest heat, 67°, occurred on the 29th in 1853; and the lowest cold, 26°, on the 3rd in 1845. During the period 118 days were fine, and on 120 rain fell.

A COMPOUND SYSTEM OF HEATING.

HAT about the frost, the winter, the Kiddean system, the Polmaise, and the pulmonary systems, the geothermal process, the damp, the dry, and the top and bottom heat? Is this disease of variegated plants the effect of too much or too little heat? Or, is it pulmonary, or is there a pulse at all in vegetables to be deranged by accidents, or by the hand of man?

A bright article might be written on each one of these heads, and as many chapters as would fill a book, and not exhaust the subject either.

The first part of the subject is thus favourable to us and ours of the flower gardens. The week on which the 10th of October came in this autumn, passed off without any signs of frost, and that used to be the sign to old gardeners that there were nine chances to one that the next six weeks would also pass off without much frost, or no more of it than to pinch Geraniums without killing them, and I hold it to be a natural fact, that old gardeners and old sailors are better judges of the weather than young philosophers.

Now, just at the moment I am writing this, I am getting in the "materials" for a system of heating quite different from all those just named—quite new in the creations of man, and yet embracing some of the best points in every one of all the systems of heating that were ever applied to gardening, save steam alone; but I am not yet quite sure if steam shall not be the final result of all my labour.

Recollect, I must pay every farthing of the cost out of my own pocket, which is but a very shallow one indeed. Therefore, what I shall do now for myself will be the best and cheapest thing that all my experience will enable me to accomplish with the smallest possible outlay. But, recollect, also, that I would not recommend anybody to do what I am going to do for myself, until the world has gone once more half round the sun, and by that time I shall be able to tell if I made a good hit or a fool of myself. I mean to accomplish the following things if I succeed:—To have moist bottom heat to force Roses, and to grow any plant plunged in damp bottom heat up to *Colocasia metallica*; in the second place, to have the power of changing this most agreeable, mild, moist bottom heat into a dry heat, in the twinkling of an eye; in the third place to be able to have dry top heat, half dry top heat, or moist top heat, at will and pleasure. And from the very same apparatus thus at work to get dry heat for my pit plants—that is, my bedding-out stuff and stuff like it, and at the same moment and by the very same contrivance to have a mild April afternoon temperature for a viney over my right worthy Esperone Vine. Since Capt. Hopkins had excelled me in out-door

Grapes, I resolved to match him in his conservatory Grapes, which were particularly good this year.

Since I heard of the first failure of the Polmaise system of heating, I have been growing this system, and endeavouring to ripen it in my own brains. The Polmaise is very nearly the system by which the heat round the world is managed by natural laws. But no one ever yet succeeded in managing the Polmaise as Nature does the other.

The growth of this way of heating was going on just that way from the first, until I sounded Mr. Kidd about his way of heating, and that was a godsend to me, for I made four years' growth out of him alone, for I see quite plain that he has gone the nearer to the best plan than all who tried the Polmaise law of Nature plan put together. All his system wanted to be absolute perfection both in practice and theory, was the not sucking back the cold and cooling air from the house, and the lack of moisture in the air he supplied to heat. But then his plan was quite sufficient for his own wants at the time, and he succeeded perfectly as far as he went. I go a great deal farther, I Polmaise a pit seventeen lights long, I top and bottom dry or moist heat three lights at one end of the pit, or at least am going to try; I dry heat fourteen lights on the principle of the old flue, but without smoke, and my viney which will be 18 feet by 16 feet, owing to the situation, or nearly a cube of 18 feet on the side, will be Kiddean and Polmaise together. All this from one small fire in a roomy fireplace, as all gardeners always recommend.

From our own pages I have had a constant supply of information, and I am greatly indebted to the fertile brains of Mr. Fish, in the matter of fires, and flues, and pipes, and in their various arrangements.

Well, then, under the first three lights of my cold pit, at the farthest end of the range, is a Kiddean hot-air chamber, which is of the same size as the body of the pit, so to speak, the back wall and the front wall of the pit being the two sides of the chamber. A cross four-inch wall divides the three lights from the rest, or from the other fourteen lights, and that makes the farthest end wall of the hot air, and the end wall of the range makes the other end of the chamber; the fireplace, or rather the furnace-door is flush with this wall, so that the ash-pit and fireplace are all inside the pit. The fireplace is in the centre, and is 18 inches long, 16 inches wide, and 16 inches high in the centre. The top being an arch of good, hard-burnt bricks. At the farthest end of the fireplace is a rise of three bricks to the smoke-flue, which goes in a straight line, and on the ascent to the farthest end of the chamber. This is all the fire I have, and it can be cleaned with a long pole and a brush from through the fireplace, without disturbing anything.

At the farthest-off end of the flue begins a coil of glazed earthenware pipes 6 inches in the bore. The first pipe is an elbow bend, the bent part joining the flue. Here there is a rise in the draught the length of the bend. This pipe is turned to the left, or to the front wall of the pit. Another bend at the wall turns the

pipes back along the front wall to the end of the arched fireplace. Another bend allows the pipes to pass across the pit to the back wall at the farthest end of the arched roof over the fireplace, and two more bends bring the coil right round the chamber and gently rising their whole length, and the spaces between them and the flue in the centre are filled with rubble. Over this space is a foot in height free from anything, then the roof of the chamber, which makes the bottom for the hotbed in the three lights.

The roof is of strong pieces of wood 9 inches apart resting back and front on a ledge in the brickwork, and is further strengthened by a centre bearing a four-inch wall, pigeon-hole fashion over the flue. This is strong enough to carry a castle, but inch slate bearers would be preferable to my wooden ones. Common pantiles, such as for roofing, is the covering over the bearers, and 2 inches of rough gravel over the tiles finish the chamber most completely, and dry heat or moist heat can be raised between the tiles and through them, when they get hot, freely enough. Then fill in a bed of the cocoa-nut refuse, which never dries, in place of tan, and the three lights are ready for hotbed work, fit for Pine-Apples if you choose, or only mild enough for Roses and Violets if you will it.

Now, for top heat and for a mild moist heat of about 80° to 90° in the air within the chamber, which ought to impart a heat of from 70° to 80° to the cocoa stuff above, and to the pots plunged in it.

The constant moist bottom heat which need not vary 5° in two months, in December and January, is obtained from an evaporating zinc pan placed over the arch of the fireplace. The sides or abutments of the arch being carried up as high as the crown of the arch, and the space filled in with grouted lime and gravel. There is a level bed for the evaporating-pan, and there is a trap-door in the end wall over the fireplace to fill the pan and to see how things look in the mist and vapour inside, or to withdraw the evaporating-pan or empty it, if a drier air is necessary to what one is aiming at.

For top heat, three-inch glazed pipes join to the end of the coil in the chamber, rise through cocoa-stuff-bed at the farthest end, and pass on in front and across over the fireplace, up the back wall, and out at the very corner of the pit, and the damper to regulate the draught is a flat piece of plate iron laid loose on the top of the pipe or chimney, if you like it better. When the flat piece of iron covers the whole bore of the pipe, there is no draught and any amount of draught from nought to the capacity of the bore of the pipe can be given by a move, and the thing could be regulated by a child.

The air in the hot-air chamber, if it is intended for anything I know of in gardening, need never be hotter than 100°. That is the whole secret of Polmaise. Oftener than not 80° will be quite sufficient, and you may get up that degree of heat in the middle of the day, and be sufficient to last that evening and the whole night, with no disturbance or addition to the fire, provided your fuel is of a description to burn in a smouldering way with very little draught.

There is a six-inch common unglazed earthenware-pipe communicating between the cold part of the range and the very bottom of the air-chamber, at one corner, the back wall corner, and there is a two-inch plain draining-pipe communicating with the hot-air chamber, and running just like a flue all along the front of the pit, just to keep out the frost and no more. This flue-pipe heats, or is supposed to heat my humble pit without letting any of the hot air escape into the pit more than if it were smoke.

The viney which is to be, abuts on the other end of my cold range, and the hot-air two-inch pipe after passing up through the range and heating it, discharges the hot air into the viney, just as Mr. Kild's air-flue does in the conservatory.

If the heat from the two-inch pipe is not sufficient for my plants in very cold weather, I can by a slide let in a whole volume from the air-chamber at once, or I can leave a small opening here and there in the joints of the two inch pipe for the escape of as much hot air as will be necessary.

I intend the air in my hot-air chamber to be always as damp as the heat will hold in suspension, and I believe the length of porous earthen-pipes between the hot-air chamber and the viney will suck so much of the moisture from the air in its passage to the viney, as will render it sufficiently dry not to hurt any plants in the viney. So that instead of risk from dry air from a common fireplace, my attention must be directed to see the air is not too moist at any time; a pull at the evaporating-pan will soon settle that question.

D. BEATON.

CULTURE OF ALOCASIA METALLICA.

IN answer to "AMATEUR," we have to state that it requires as much strong top and bottom heat the year round, and as much moisture in the air all the while as succession Pine-Apple plants. But, like many of the old associates of the Pine-Apple plant in our early Pine-pits, good gardeners can now manage such plants without bottom heat, only the moist air of the common stove, and that is how this *metallica* is grown to perfection in the Kingston Nursery. Sixty degrees is about the average heat of that stove all the winter months; but, of course, it is down to 55° at times, when it is very cold, and up to 65°, and higher, when the sun plays on the glass. From October to the end of March it is best to have such plants as this, with their succulent parts, in rather a dry atmosphere; but when they, and this one in particular, are growing in earnest, the air of the house cannot well be too moist.

All this race like a generous soil. Such as they use for the very best show Pelargoniums is just the very soil for *Alocasia metallica* as soon as it is out of nursing compost, which, of course, is always, and for all plants more or less sandy, or peaty and sandy together. A young Firely Pelargonium likes plenty of sand and leaf mould with the loam till it is out of 60-pots, and all pots of that class, and it is just the same with *Alocasia metallica*, and with five hundred kinds of plants which stand, in botany, on each side of it.—D. B.

NOTES ON SOME OF THE FRENCH NURSERIES.—No. 2.

MONSIEUR ANDRÉ LEROY, ANGERS.

WHOEVER would form his estimate of the extent and importance of the French nurseries from those in Paris would be greatly mistaken; and therefore, although I have notes of many others both of the metropolis and its environs which I shall hope yet to give, I prefer bringing before the readers of THE JOURNAL OF HORTICULTURE a short account of perhaps the most remarkable nursery in the world—that of Monsieur André Leroy, of Angers.

Angers is the very paradise of French nurserymen, and of them all M. Leroy is "the king." Situated as it is in a climate where the more tender things of the South not only grow but produce their fruit in the open air, and enjoying a fertility of soil which seems to be capable of producing anything, and not subject to the extremes of temperature (owing to its nearness to the ocean) which are experienced in the interior of France, it seems not only to be admirably adapted for gardening purposes, but to have been so appreciated by the French nurserymen; for in the environs of the town there are upwards of 500 acres of land so employed, and of these 300 are in the occupation of Mons. Leroy, whose object it is to cultivate simply such things as are capable of being grown in the open air in France; so that, save for the purposes of propagation, there are no green-houses on the property, and the productions of tropical climates do not form the subject of his care and attention. To attempt to give anything more than a very rapid sketch of such an immense establishment would be utterly useless; and therefore my object will be simply to notice those points which most forcibly struck me in the drive which we took through it, for to walk through such a nursery would be no easy matter, especially as my visit was paid in one of the warmest days ever experienced in France for the season of the year.

It is from the neighbourhood of Angers, Nantes, &c., that the largest exportation of Pears takes place to Paris, England, Russia, &c. Many of the fine specimens of Glou Morceau, Duchesse d'Angoulême, &c., which we often see in Covent Garden being the production of these places. The extent to which they are grown may be judged from the fact that 50,000 lbs. weight of Pears have been sent from the railway station at Angers daily for the last two months, and the supply is by no means yet exhausted. This leads, of course, to the necessity of having a large supply of trees; and M. Leroy has nearly 500 varieties of the fruit in his collection, grafted either upon the Quince or seedling Pear stocks. He has a large collection of fine pyramids, from which the workmen were then gathering baskets of noble-looking fruit. Some idea of the rapidity of growth may be formed from the fact that the seedling stocks of a year old were 4 feet high, and that those grafted the beginning of last August (1860) were now upwards of 5 feet. Apples are grown also in

a very extensive manner; and there are upwards of 300 varieties of Grapes for the table, none of the wine-making sorts being included. In passing along I noticed the Olive tree in a sheltered spot in the garden in full fruit; also two or three varieties of Malus, such as Torenago and bæcata fructu rotomagensis, which have large quantities—the latter being those beautifully high-coloured little Apples so daintily arranged in boxes in Covent Garden, and called sometimes Lady Apples. Here also we found the Pomegranate in fruit, though small and not ripe. On the walls Peaches were grown. They are grown, as I find, very extensively in France now on the system of "Debrueil;" and certainly it seems to be one capable of producing a much larger quantity of fruit in the same space and in a shorter time than the ordinary method. It has, no doubt, been described in THE JOURNAL OF HORTICULTURE; and therefore I shall not trouble your readers with a repetition of what has been, I dare say, better done before.

It would, perhaps, hardly be expected that a climate and soil suitable for fruit trees would answer for Conifers; but the peculiarity of both about Angers is that they seem to answer all kinds of trees. On entering the nursery there was a fine specimen of Wellingtonia, the stem of which was 1 foot in diameter, and it was only six years old; while *Cedrus deodara* was so luxuriant that trees 6 feet to 8 feet high were only six francs a-piece. *Rhododendrons* flourished here too; and the system of propagating is that of layering the bush down at all points, and thus producing hundreds of plants round the parent. This plan was formerly adopted in England. Probably the most striking thing in the whole nursery was the immense number of Magnolias. These were to be found in all directions and of all sizes, there being upwards of 25,000 of them, chiefly of the variety *M. galliensiensis*. Although not so free-flowering as Lord Exmouth, it is much more hardy, and might perhaps, therefore, be worthy of more consideration in England. Standard trees 8 feet high were to be sold here for two guineas. A very fine *Cotonaster* (*nepalensis*?) with large bright-looking fruit, and *Thea viridis* in bloom in the open air and quite hardy, also attracted our attention; and *Elaeagnus reflexa* in full bloom was very fragrant, and perfumed largely the air around it.

In a sheltered nook on the wall was growing a very remarkable-looking plant, which I should think would answer admirably for a greenhouse climber. It is not new, and yet I think is comparatively unknown, and is called *Phaseolus caracasana*. The buds are exactly like a ram's horn, twisted in the most curious manner. It is a papilionaceous plant, blooming in racemes like the Gleyne; the colour white and lilac, and the fragrance of it very delicate. In appearance it is one of the most curious-looking flowers I have ever seen, and I think would be a favourite, as it seems easily grown and would rapidly cover the rafters of a house. *Cæmelias* are grown here on a most extensive scale in the open air, tens of thousands of plants of all varieties being found in the nurseries; the only protection they ever receive being that of mats to shade them from the burning sun. But I shall have more to say of these when giving a few notes on Mons. Cachet's nursery, and must conclude this rapid sketch with a brief notice of what to me was perhaps the most interesting of all portions of this vast establishment—the Rose ground.

It is, I dare say, well known to most of your readers that Mons. Trouillard, the raiser of *Eugène Appert*, François L., François Arago, Reynolds Hole, &c., is M. Leroy's Rose-foreman; and as his seedlings are cultivated in a piece of ground near his own house, I shall not refer to them at present; but the Rose ground was filled with a large stock grafted, budded, &c., on their own roots. So great has been the demand, however, this year for them from England, that very few of anything like new Roses were to be obtained, and vast numbers of the others were marked off as sold. There was one point in the cultivation of them that, however, struck me as novel and good. The *Manetti* is acknowledged now to be a very valuable stock for strong-growing Roses; but in the case of many of not so vigorous a constitution, the bud, not having sufficient vigour to receive the sap of the stock, becomes soon overpowered, or else a vast quantity of suckers are thrown up; while often the Dog Rose obtained from the hedge has not sufficient root to impart vigour enough to the Rose. To meet these difficulties it is the custom at this establishment to sow the seed of the Dog Rose, and to graft low down on the seedling plant those varieties, such as *Madame Furtado*, &c., which are not of the vigorous constitution that others have. I cannot but think that this affords a useful

hint to us in England; and doubtless the Rose itself would root and thus become almost on its own roots, while at the same time it would be more long-lived than if on the *Manetti*. I found that some sorts which are regarded as fine in England are not well thought of here, and *vice versa*. *Reine des Violettes* being considered fine, and *Due de Cazes* good for nothing; while some seen to come equally fine in both countries. It is the same in every kind of flower; I saw at Mons. Rougier-Chauvrière some of our finest Dahlias most complete rubbish.

I cannot close this notice without alluding to the most kind manner in which everything was shown to me (as a friend of Mr. Standish's) by Mons. Baptiste Desportes, M. Leroy's partner, or to the hospitality which I received at the house of M. Leroy himself. One rarely meets with one so full of anecdote and *bonhomie*; and surrounded as he was by a family whose names are well known to us as Rose-growers—his son-in-law, M. Eugène Appert, and his grandchildren, Messrs. Thèse and Marguerite Appert, with his aged mother-in-law, it was a pleasant sight to see the affectionate intercourse of four generations, and gave me a most favourable view of French country life. I shall ever retain a lively recollection of one of the most pleasant and interesting visits I ever made; and shall be glad if I have made what I saw anyway useful to your readers.—*D., Deal.*

TREATMENT OF OLD VINES IN A VINERY.

I HAVE this summer changed my residence, and at my new place there are two vineries, with which I am rather puzzled how to proceed. The previous owner and occupier of my house and gardens, looked after the vineries himself as an amateur; and I hear that for years past he has allowed the Vines to bear the heaviest crops he could possibly get. The Vines are naturally feeling such overcropping, particularly as the border is a very insufficient one at the best, and indeed, how the Vines have borne such large crops as I am told they have, is to me a mystery with such a border.

The Vines are White and Grizzly Frontignans, Black Hamburgh, Black Tripoli, White Sweetwater, a large white *Spanish* Grape (I think), in all seven or eight Vines in each house. The Vines have been trained each with three equally large leading stems, so that the whole surface under the glass is equally covered all over with leading shoots. This proves very bad for plant growing, as it excludes anything like a good amount of light to the plants below. This is one of my difficulties.

The border is a miserable one. It is only about 4 yards wide, from the front of the houses to a hard gravel walk, and it is nearly flat; very little slope from the front of houses to the walk. The other day I made my man dig holes opposite two or three of the Vines, but on the far side of the gravel walk, about a yard into the vegetable-bed beyond, and at a depth of 18 inches to 2 feet, we came to numerous fibres of Vine roots, none thicker than a crow-quill, but many of them clearly showing that the Vines had travelled right under the gravel walk, and into the vegetable-beds beyond.

Now, what I wish to know is, how best to proceed to renovate the border. If I confine the bones, manure, &c., to the present border, I am afraid the points of the roots are mainly in the bed beyond. If I move the gravel walk further back, and dig up the present gravel walk, I am afraid of exposing and injuring the Vine roots beneath it, and if I do not do something to keep the Vine roots from wandering further still away in the beds opposite, I shall never know where to have them, and where to apply stimulants. What would you advise? The border must remain nearly flat; a slope cannot be got. The houses have a due south aspect, and are in a warm, dry soil. The Vines are remarkably free from disease. They had large crops (far too large) left on this year, and consequently, the Grapes have been small, and not coloured well, and the Vines evidently want a thorough root-refreshing.

Would you also advise how many bunches are enough to allow each Vine to set?

Can I this autumn safely cut away from each Vine all but one leading shoot, so as to train them on one and not three?

The house that is usually forced first has good fire heat sufficient to heat well; the other house which only small hot-water pipes, just enough to keep out frost.—*G. R. V.*

[From all you state we should decidedly say, Leave well alone. Most likely the roots have got something nice below the

gravel walk. If the surface soil on the old border is exhausted, add a little fresh, after removing all the old you can without injuring the roots. Your thinning out the shoots, and thinning out the bunches, will cause more strength to be thrown into the bunches left; but all growing of Vines and plants must ever be matter of compromise. If one Vine stem is left to a rafter—say a feet apart, and fine bunches are wanted, from nine to fourteen bunches may be taken. Most likely you may have twenty to forty from the different stems. Perhaps it would be as well to leave one stem the whole length, and one more half the length the first season, reducing the number to one stem afterwards. The roots, be assured, in such circumstances as you describe will look after themselves, and if not deeper than you state, will neither cause want of colour nor want of swelling. Try one year at any rate, and if that does not please them, renovate the border and lift the Vines, and keep them to the desired width if you deem that desirable.]

CINERARIAS BLOOMING PREMATURELY.

I HAVE some fine large Cinerarias, this year's offshoots, and they are showing bloom-buds. Unfortunately my greenhouse has very little sun from November till February. Would you advise me to pinch the buds out, to throw them back? I intend keeping the greenhouse about 45° in the winter, but am afraid the bloom will not expand without sunlight.—J. A. F.

[You had better pick out all the forwardest and let them bloom. The rest nip off any incipient buds and report in larger pots. Whenever Cinerarias fill their pots with roots and get matted, they will throw up flower-stems, whether the plants be in small 60's or large 12's. At the heat you speak of, the flowers will open nicely. You must keep the later plants at the coldest end, and it would be as well if the pots stood on damp moss.]

SYCAMORES UNHEALTHY—MAKING A CARRIAGE ROAD.

ABOUT twenty years ago a plantation was turned into a garden. Several trees were left standing, and some of them being tall and slender were bound with iron to keep the stems (two or three), together. The iron appears to injure the trees, as the leaves turn yellow very early, and the topmost branches are leafless. The bark has overlapped the iron. Can I save the trees by taking off the iron bands, cutting away the bark which has grown over them, or would this weaken the trees too much, or otherwise injure them? The trees are all Sycamores.

Please to inform me how to make a good carriage road. I can get chalk, sandstone, gravel, and sand. My soil is a light loam.—G. B.

[We fear there is something else the matter with your trees than merely being iron-bound, although that, doubtless, does some harm, and we cannot well understand why it was done; but Nature is so accommodating as to cause the swollen parts of the wood above and below the band to unite and grow over the ligature. This is often seen in young trees that have been tied up to a stake and the tie not loosened in time. Perhaps your trees are suffering at the roots. Examine them and see if there are any leaky gas-pipes, or has any pernicious chemical substance come in contact with them. Generally speaking, the Sycamore is one of the most hardy of all forest-trees, and not particular as to situation. If you cannot find out anything at the roots you might take off the bands if you can do so without cutting away much of the newly-swollen enlargement; but if you cannot get it out conveniently, merely cut it in two in one or more places, and also reduce the head by cutting away some of the more sickly branches, or you may cut it off entirely, making a sort of pollard of it. Early in the autumn is the best time to cut Sycamores, as they bleed much when cut in February or March. If your trees do not show signs of improved health next year, write us again, stating more particulars as to situation, and if you be injured in any way by factory smoke of a poisonous kind—that from soda being very obnoxious to vegetation.

You may make a good carriage road of the materials you name, by not excavating the line more than 3 inches or 4 inches, and if it be in the least inclined to be wet, let the foundation slightly incline to the centre, and run a drain there, filling all above it with rubble stone. Break the sandstone to the usual

size of road metal, and lay it on quite to the height of the tur edging, and upon that lay on some hard gravel that has had all the finer sandy matter sifted from it, so the top edges of the sandstone will grind down with the carriage wheels to make the road smooth, only you must recollect that all depends on the hardness of the gravel for making a firm good road. Softer material cuts so with the wheels. Many gravels are flinty, but when hard gravel is not to be had, other hard stone broken very fine answers quite as well. We have seen some such stones broken by the inmates of union workhouses, and sold at a cheaper rate than could be obtained in any other way.]

THE PEACH TREES AT THE CRYSTAL PALACE SHOW.

WITH OTHER REMARKS ON ORCHARD-HOUSES.

By an oversight I was not aware that the few stray notes I had made on the late Crystal Palace Show and its gardening had been received with so much animadversion by one of your readers until it was too late to reply by last week's publication.* I now, however, endeavour to reply to some of his somewhat personal observations, which compel me to be more egotistical than I otherwise would be, and which I have endeavoured as far as possible to avoid. But as the matter of orchard-house cultivation of trees in pots is engrossing considerable attention at the present time, it is to the general reader that I now address the following remarks, leaving "A CONSTANT READER" to form his own conclusions.

My acquaintance with Peach trees in twelve-inch pots commenced about 1831. How long prior to that date they had been cultivated in that way I cannot say, but at the date I mention they were regarded as novelties, but not new; and although, I need hardly say, I had not the charge of any at that early time of my life I had a fair share of the management. The cultivation at that time being to place the trees in any glass house that was light enough, and when there was room for them (and glass houses in those days were not so plentiful as now) and the usual attention in watering, syringing, disbudding, and the like being gone through at the proper time, the trees were set out of doors in a sunny sheltered place some time before the fruit ripened, and a crop of fruit precisely of the same character as the majority of that obtained now was the general result, which was that of their being about two-thirds, or say three-fourths, of their proper size.

I may further inform the general reader that at the time the trees were set out in the sun, the pots were neatly bound round with hay or strawbands to keep them moist—a plan that is now met in plant culture of other kinds by inserting the pot in another and larger one; but the pains taken to bind these strawbands neatly around the pots formed a job which young men were proud to show their skill in, much the same as they now do in a due distribution of sticks and string in a specimen plant. But the Peaches and Nectarines (for I do not remember any other fruits attempted to be so grown in pots) were seldom, if ever, to be compared with the medium-class fruits obtained from trees grown in the ordinary way, and certainly never approached fruit of a first-class kind; and the same may justly be said now.

As orchard-houses, on what is called the improved principle, have existed for some years without in any one instance that I have heard of producing fruit from trees in pots that was fit to compete at a horticultural show with those grown in the ordinary way against walls or in Peach-houses, and at the most important fruit show in England—that of the Crystal Palace; some trees sent there for exhibition, and occupied a prominent position on the tables, are pronounced by "A CONSTANT READER" at page 498 as "poor specimens of orchard-house culture, and ought not to have had a place in the Exhibition"—a disparagement, by-the-by, ten times worse than what I said about them, and one which tends more to confirm what I have before said of the inutilty of Peach trees in pots, excepting for purposes of novelty, than "A CONSTANT READER," perhaps, intended it to do; and, as one of those who like to see a Peach larger than a Green Gage Plum, I thank him for pointing out how small those were that were exhibited at the Crystal Palace. At the same time, it is only fair to the grower to say that the trees had an excellent crop of fruit on, and showed as good an example of gardening as anything there.

* By an oversight the publication of this has been delayed.—Eps. J. O'H.

Although I have no great pretensions to the character of a traveller, I generally ramble over some hundreds of miles each year, and am not yet too old to learn anything useful or new, and I may tell "A CONSTANT READER" that I would go a good long distance to see a dozen really good fruit on a tree occupying a pot only of the size of those exhibited at the Crystal Palace. I do not want to see potted trees standing on the ground with their roots occupying that ground in all directions. Such fruit are not grown on potted plants any more than some Grapes exhibited at a country show, and justly disqualified by the Judges, as detailed in THE JOURNAL OF HORTICULTURE a short time ago. But I believe the trees exhibited at the Crystal Palace to have had no "ground assistance," and as objects of cultivation they deserve every credit; certainly more than "A CONSTANT READER" (and he, too, an advocate for potted trees) gives them. Nevertheless, as a mode of growing Peaches, I saw nothing about them but what confirmed me in the opinion that it is a costly and uncertain way of obtaining fruit; and though it may not be quite so bad as the Irishman's horse that was bad to catch when turned out, and when caught good for nothing, still Peaches and Nectarines grown in pots of a size that one man can move about has a much closer resemblance to the two faults of the poor Irishman's horse than is often admitted. Those having enthusiastically entered into the growing of such trees and found it fail, have naturally enough an aversion to publish their want of success, and their silence makes the few successful ones the more vehement in praise of their hobby.

Let us now take a view of an orchard-house in another mode of cultivation; trees planted out and allowed to assume a certain amount of bush-like character, and we are told they bear well, and the fruit is good. This I have not the least doubt of—on the contrary, I have seen Peaches and Nectarines in exactly the same condition twenty-nine years ago. A lean-to house, not called by the ambiguous name of "orchard-house," but simply a "Peach-house," had trees trained against the back wall in the usual way; and in the front trees were planted and trained (if the little pruning and tying they received could be called training) in the bush fashion. The house being a tolerably wide one with glass in front allowed this to be done pretty well, and the trees bore as well as trees in a general way did bear. How long before 1832 this house had been so occupied I cannot say, but the gardener, who was fast verging on seventy years of age, spoke of his father having had better crops than ever he had had; nevertheless, he did not admire the wild appearance the trees had, and often wished for a front trellis, as it was necessary to stick in stakes here and there to tie an unruly branch down a little, and another branch being, perhaps, tied to that one. The appearance was not nice, and the trees being old, perhaps twenty years or more, it was not easy without such tying to present anything like a healthy centre at all times. Cultivators dating back from 1859 may, perhaps, think differently, and it will be fortunate for them if they can avoid the evil here spoken of, and continue to have successful crops and healthy trees for a period of half the extent of those of the old gardener I allude to.

Having detailed what fruits were grown in years gone by in precisely the manner now advised by orchard-house revolutionists, it is only fair to say what I never saw attempted. I never saw Pears or Plums so grown. I have seen Apricots, and I believe Plums worked on the Peach, but it was only by way of trial, and I think was not successful; but Cherries have been certainly grown in pots from a very remote period. An old Archduke Cherry was once pointed out to me which had witnessed the passing away of several generations, and which tradition reported as having originally occupied a flower-pot; but whether so or not, some of the early numbers of Loudon's "Gardeners' Magazine," published in 1825 and subsequently, mention instances of success and failure in that way of cultivating Cherries, both being common then as well as now.

That this need not be further alluded to, I may also add that in years gone by I never saw a glass house resting on a hedge as a foundation, as is reported to be the case now in some places, brick or stone work being in every instance, that came under my knowledge an indispensable portion of such structures. I do not here find any fault of the means made use of to construct glass houses cheaply—on the contrary, I admire such as are in really cheap; or, in other words, such as are after a lapse of years proved to be so, as we all know it is not everything which costs little money that is cheap, in the true sense of words, whether such articles be clothing, furniture, or glass house—time alone tries them all.

To those who have paid much attention to gardening matters the last quarter of a century or more, it is needless to ask how many objects, or things strongly urged at certain times, have fallen into oblivion. Some time after the first monthly gardener's periodical that came into existence, edited by Mr. (now Sir Joseph) Paxton, and Mr. Harrison, orchards, in miniature, were strongly recommended by some enthusiast that way, and pictures of Apple, Pear, and other fruit trees bearing bushels of fruit within the easy reach of a child were presented to view; and such like orchards were recommended as very good adjuncts to dining-rooms, where the company could walk out and partake of the delicious fruit fresh from the tree. This luxury is so far short of the one offered to notice at the present day, inasmuch as the present temptation has the advantage of a house covered with glass. This "very fine" state of things, however, like most other pleasant illusions had but a short duration, and miniature orchards in a short time vanished into still more diminutive proportion, having previously reduced the purses of their advocates in like manner. The only vestiges I have seen of these novelties was one near Bolton, in Lancashire, where a large space in a garden was covered over with wirework, to exclude birds, which, like all other biber members of the creation, were to be denied admittance to this paradise of horticulture. Unfortunately from some cause that the maker never expected, the trees would not grow and produce fruit, and the large wire cage was all but empty when I saw it some three or four years ago. Orchard-houses are certainly better than this, and, if in the hands of a gardener, he is sure to make them useful one way or another; if Peaches trees refuse to bear respectable fruit in pots he will turn them out, and they will then do so I have no doubt. Only give him the house and he is sure to turn it to account; only I would advise those about erecting one not to be too sparing in expense at first cost; not to lay the plates or sill on the naked ground, but to have brick or stone foundation of some kind; and better still if they contrive to have this foundation to consist of pillars, so as to allow the roots of trees planted inside to pass through; timber posts may do, but if well done must be more expensive than brick, and Larch or Scotch Fir trees of 6 inches or 8 inches in diameter, last in such places not a day longer than they will do elsewhere, which at the outside may be some half-dozen years.

In taking a view of other whims to which horticulture, in common with everything else, has been guilty of, one of the first projects the introduction of cheap glass brought into view was glass walls. These costly appendages, however, soon gave way, and by degrees expanded themselves into full-sized houses, with their heating could be applied. Fruit in basketfuls was predicted from such transparent walls; but John Bull after the first impression could not see it, and glass walls are as rare as miniature orchards.

As years rolled on revolutions in other departments were threatened, and *Spergula pilifera* was expected to drive every inch of turf from our lawns; and a nobleman once told me, in serious earnest, that he feared if this *Spergula* was to get anything like a firm hold of any particular place it would drive all our grasses out of the field; and, like the *Anacharis salsinatum*, which has become so great a pest to the canals, this *Spergula* would become the pest of husbandry, changing by its marvellous powers the very face of the earth. When this is to take place I do not assume to foretell, but its fitness to do so is about on a par with glass for fences, and orchard-house fruits for principal market supplies, that I anticipate the trio will go in unison.

Having said sufficient about the cultivation of Peach trees in pots in years gone by I may be allowed to say that I have not had any for eight or nine years; but before that time had several, which bore fruit of a medium description, or perhaps a grade or two below that, in the same way that similar trees do now in a general way, but at a great amount of trouble in watering and attending to. I may, however, inform "A CONSTANT READER" that I have seen several orchard-houses, and some in which the owner prided himself not a little in the number of fruits then growing on the trees, but an awkward apology was to be made when they were to be a ked for at the proper ripening time. I have also seen others where conviction had done its duty, and the very ugly wood hubnag (I beg pardon for using it) was applied to the whole thing. Others who had, doubtless, in a certain manner become sponsors to the said orchard-houses, and desirous of their doing well, wisely turned the trees out of their pots into a well-prepared border and exultingly pointed out

the result in the healthy condition of their trees, and the little trouble they caused—a matter in which I cordially coincide. At the same time, a less ambiguous term than orchard-house ought to be used; a savage's canoe might as well be called a man-of-war. An orchard is generally expected to produce fruits in tolerable large quantities: I have seen for sale Marie Louise Pears grown on open standard trees as well as *à la bushel*. Query, How many bushels would half a dozen orchard-houses furnish? Yet we are told Pears can be profitably grown in these structures. But I have already said enough, and will leave the further commendation of Peaches in pots to "A CONSTANT READER," since he has done more to disparage those at the Crystal Palace Show than I did; and in regard to the other fruits there, if he reads the heading of my article he will see that I did not assume to describe all that was at the show, but merely to point out such things as I thought worthy of particular notice. J. ROSSON.

CULTURE OF THE PINE APPLE.

(Continued from page 11.)

HEATING.—*Bottom Heat.*—Spent tanner's bark, 3 feet deep, makes a very excellent medium to plunge the Pine-Apple pots in. The heat sometimes, however, is too violent, partly through the want of due preparation; the watchful gardener will soon perceive this, and the moment he has ascertained that the heat is approaching the danger point not a moment must be lost, the pot must be lifted out and set on the surface, and allowed to stop there till the heat is on the decline; as soon as it declines to from 75° to 80° the pots may be plunged in Oak and Beech leaves. These make a good bed for bottom heat. Gather them and lay them in a large heap, turning them once or twice, and if dry sprinkle water among them; cover them with mats to keep off heavy rains, and in six weeks they will be ready for use. The heat from leaves so prepared lasts longer than when bark is used and is more agreeable to the plants. However, if bark can be had easily place a layer upon the leaves to plunge the pots in.

Hot Water for Bottom Heat. This, when judiciously applied, is excellent, and can be regulated to a nicety in regard to temperature. Under the beds where the Pine Apples grow, whether in pots or planted out, there should be a chamber, and in that chamber a large tank filled with water, through which pipes filled with water and connected with a boiler should run, ascending and descending to have a due circulation. This method has the advantage also of being clean and tidy, and there is not at any time so much trouble in preparing the bed as is the case where bark or leaves are used. If the plants are grown in pots, there must be something to plunge them in, even when bottom heat is supplied by hot water. As that something is not required to produce bottom heat, of course the pit to hold it need be no deeper, or very little than is necessary to hold the pots level with the rims. Bark, or sawdust, or even sand, may be used for plunging in; the last being the cleanest and least liable to breed worms or other insects. I have seen Pines grown successfully by having a platform of boards with holes cut through to suspend the pots in as it were, over or in a chamber heated with hot water, and good Pines were produced thereby; but such a method requires so much attention and expense to keep up a regular bottom heat all through the year, that I fear its permanent adoption for the purpose is not likely to become general: still I conceive it is worth further trials.

Steam for Bottom Heat.—At Horsforth Hall, a place I have already referred to, the houses were heated by steam sent round the houses in shallow, tight, stone flues, and under one large pit jets of steam were thrown in similar cavities at intervals. The pit was filled with bark, and certainly the occasional throwing in the steam had the effect of keeping the bark warm much longer than if no steam had been used. The grand objection to steam used any way to supply heat is that before any heat can be obtained the water must be got up to boiling temperature (212°) in order to produce steam; whereas in the hot-water system heat is generated as soon as the fire is lighted; and, besides that, the expense of a steam apparatus is much greater, the boiler being very much larger, and the fireplace also of a proportionate size requires a larger amount of fuel: hence steam is now, I believe, quite gone out of use.

This completes the section on the proper habitations that the grower should provide for growing this delicious fruit. He will put up three houses for the different stages of growth; he will

provide for a supply of heat both for top heat and bottom heat; also means for giving air, and as in certain seasons the internal air should be duly supplied with moisture, he will obtain this by having evaporating-pans fixed on the hot-water pipes, or by syringing them when warm. The season when this moisture in the air is necessary and useful is in spring and summer, to promote growth and to cause the fruit to swell kindly and equally.

I may as well state on the rather disputed point of growing them in pots when of a fruiting age and size, or planting them out at that time of growth, that certainly the finest pit of Pines in fruit that I ever saw, were planted out, and that was at Trentham, when Mr. Fleming was gardener there. From his great success I must give the palm to the system of planting cut. His fruit (Queens), chiefly were all large, well-sweetened fruit. This point, however, I leave to be decided by further trials.

VARIETIES.

During the time that the pineries are being erected, the plants to furnish them should be inquired after. Great care should be taken to obtain them clear—that is, free from insects, such as the white and brown scale and mealy bug: hence it is requisite that the gardener should see and closely examine them, and being satisfied with them, he can order at once the quantity required, and have them carefully tied up, packed, and sent home. The fruiting plants should be sent with their balls entire. If those balls are carefully mossed round they may be laid flat in either boxes or square large hampers. If, however, the place is near enough, the plants may be tied up and set in their pots amongst bark or sawdust in a large-enough van, and thus they will travel securely and safely to their destination. Succession and nursing plants may have the greater part of the soil shaken off the roots, be packed in moss, and the leaves tied up snug, and in that state they may be packed in large, square hampers and sent safely by rail to any distance.

In selecting the varieties the cultivator will bear in mind two or three points. First, Are the Pines required for any particular season, for there are, happily, sorts that will be good in winter, and others that are suitable for summer; also, secondly, whether large or medium-size fruit are esteemed; and, lastly, if the fruit is required all the year round.

It may be, that my readers would be glad to know where they could procure Pine-Apple plants in quantities and qualities to furnish a moderate-sized stud of pineries. Some years ago I used to obtain Pine plants from a Mr. Davis, of Starch Green, near Hammersmith. His plants were always clean and well grown. I also have had good plants from Mr. Wilnot, of Isleworth, but he being dead I do not know whether his successor keeps up the stock. Messrs. Jackson & Son had, a few years ago, a great stock of plants in the range of houses they rented at Hampton Court. If there are any other growers of Pine plants for sale, all I can say for them is, Advertise your stock and you will get customers for them no doubt. Many private gardens dispose of their surplus stock of Pine plants. If I wanted such I would advertise for them at once, and I should not fear obtaining any quantities that I needed.

The best season for these exotic plants to travel is, as a matter of course, during the summer months. They might, however, be so securely packed in the earlier and later months of the year as to be conveyed safely during those seasons.

The Queen.—I place this good old variety the first. For general purposes there are none better. It is dwarf in habit, free to grow, easily-excited to fruit, and, when well grown a good fair useful size, and its flavour is most excellent. There are some varieties of it—namely, *Ripley Queen*.—Rather stouter in habit, free to grow and fruit, rather larger in size than the old Queen, and by many esteemed superior in flavour. *Moscow Queen*.—Very dwarf, short broad leaves, and easy to fruit, favour rather inferior, generally less in size than either of the former varieties. *Welbeck Queen*.—Very dwarf in habit, leaves rather long, curving downwards; spines very large and rather thin on the leaves; fruit medium, very firm flesh of a nearly white colour; flavour good. Keeps well. In estimation about second-rate. *Fairrie's Queen*.—I first saw this fine variety at A. Fairrie's, Esq., Aighburth, near Liverpool, in whose pinery it fruited, I believe, for the first time in England. Habit dwarf and compact, leaves short and rather curving downwards, fruiting-plants not occupying more than 15 inches square; fruit large, handsome shape, rather globular in form, firm in flesh, very juicy, and well flavoured. A first-rate variety for summer or autumn; but I apprehend not so good for winter.

Black Jamaica.—Habit, rather tall with long leaves. Fruit, medium size; pips, flat; shape, a long oval; flesh melting, flavour most excellent, as good in winter as summer, keeps well. I know no Pine so good in flavour as this fine variety. The gardeners in the north of England call this variety the *Montserrat*, but as the best growers in the south name it the *Black Jamaica*, I think that should be its general name. The *Montserrat* is something like it, but more pyramidal, and soon decays after it is ripe: previous to that decaying it is equal to the other in flavour. I believe it is now out of cultivation.—
T. APPELEY.

(To be continued.)

PRUNING LARGE LIMBS OF FRUIT TREES. VARIATION OF PLANTS.

SOME time since, in your No. 26, you observed, "We cannot advise about this wall trees without more information. Cutting off branches of Peach, Nectarine, and Apricot trees, 4 inches in circumference, requires much discretion."

Now, I have cut leaders and side branches of various sizes, from 8½ inches in circumference, with perfect success; and in every case I find the bark grows over the cut. Many years ago, when in Manchester, I was shown the cut by a gentleman, a schoolmaster, who was passionately fond of trees of all kinds, and though he did not to my knowledge cut fruit trees in the way I beg to bring to your notice, I thought I would try the plan on the stone fruits, and see if it would prevent the "gumming." Well, the first year it was good, second ditto, and third the same; so now the public shall have the advantage of the schoolmaster's cut, for it is not my own, and I do not intend to play the Jackdaw among Peacocks, and strut off with plumes and honours not my own.

We learn as much by the eye as by the ear—I have, therefore, sent two little drawings, *a* the right cut. It will here be seen that the bark is bevelled down to the wood; it is easily done, no matter what time of the year the cut is made; *b* is a clean cut, and the branch will gum unless the wound be rubbed over with lime, or some caustic to burn the edge of the bark. If what I have written is not clearly understood I shall be happy to offer any further explanation.

In the summer of 1860 I found growing in my shrubbery a most beautifully-variegated young Oak. I showed it to Mr. Standish who thought it worth trying to see if the variegation would stand. He took it up himself and shook out all the poor sand from the roots, for it grew in a damp, shady, sandy place, and potted it in good soil. This year the variegation had nearly grown out, but I have taken it and put it into poor sand again, and we shall see if it returns to the variegated or comes green. As it may be of interest to Mr. Beaton I will give him the plant if he likes to experiment on it, for his word has authority, whereas I am simply an unknown quantity.—X.

[Beveling the edge of the bark is a very old mode of finishing off the stump of an amputated branch. We practised it forty years since, and then it was an old practice with our teacher. When we spoke of "discretion" being required in cutting away the large branches of Peaches and other trees, we had not in contemplation the fear of gumming, but the general disturbance of a tree's constitution, often occasioned by severe amputations. Many trees never acquire a vigorous growth afterwards.—
EDS. J. OF H.]

TIMBER FOR GARDEN STRUCTURES.

No doubt when good sound oak is used for door-frames, sills, and wall-plates, and best Petersburg red deal for rafters, sash-bars, &c., a very durable house can be made with such materials; but I am inclined to think one equally as good, and perhaps better, can be built with Pitch Pine of best quality.

My own experience of it is slight; but your correspondents speak of it as being as durable as oak for posts, staircases, &c., and amongst others whom I have mentioned the subject to, the

Messrs. Smith, nurserymen, of Dulwich, give it an excellent character. They have known it in use for many years; and I saw, when at their nursery a short time ago, they were using it for making and repairing frames. At any rate, I think of trying it for a span-roof house, 30 feet by 50 feet.

I quite agree with those who advise a free use of paint when jointing the parts together, and in contract work this is not always properly attended to. Ours is not done by contract; it is done on the place, and the carpenters have no objection to a paint-pot standing beside them.—JOHN STEVENS, Gardener, *Malvern Hall, Solihull.*

WINTERING DELICATE STANDARD ROSES.

WE have some new standard Rose trees from France. They have flowered this summer, but look delicate, and we have fears for the approaching winter. We should be much obliged for hints for protecting them during the approaching winter. Our aspect is exposed on the north-west coast of England, and very bleak and windy.

[There is no better plan for protecting delicate standard Roses than that which Mr. Rivers hit upon, and recommended for Bourbons, and such others as are like them. The plan is to take them up carefully and place them behind a wall—that is, on the north side of a wall, and the heads leaning against it. The roots, or over the roots, he mulched with some dry litter, and with mats he secured every bud when most Roses were more tender than the present race. If such Roses were planted out again at the end of February, they would bloom as freely as if they had not been moved, and after three years of that treatment any Rose which would not stand our climate ought to be frosted and done with. We followed Mr. Rivers' plan, and found it most useful.]

The next best plan is to stuff hay, or straw, or fern, which is better, in among the branches, and make it conical like a boy's rush helmet; but the standards must be well staked. Thirdly, and the most expensive plan, which is perhaps the surest, is to make a triangle with three long stakes higher than the top of the Rose tree, fasten the tops of the triangle over the centre of the Rose, and thatch the triangle like the thatch of a cottage-hive, and stuffing dry fern or hay among the branches if the winter prove very severe.]

OXFORD MILLS' CELERY AND FLOWER SHOW.

ON Saturday, September 14th, the workpeople in the employ of Hugh Mason, Esq., held a Horticultural and Floricultural Show in the lecture-room of the neat and commodious institution, recently built by that philanthropic and public-spirited gentleman, near his extensive mills. The exhibition comprised an excellent collection of flowers and fruit grown by the workpeople, with a number of choice plants and flowers from the conservatories and gardens of Thomas and Hugh Mason, Esqs. The show-room was beautifully adorned with a large number of devices in flowers, which were so well arranged that they would have been a credit to professional hands; but several of them were made by the wives of the workpeople, and the colours were so judiciously blended as to produce the most perfect "harmony of contrast." There was a little neatly-arranged stand table worked in red and white flowers, save the top, which, with purple and white flowers, was made to represent a draughts-board; another was in the form of a chandelier, and, although a pretty piece of floral ornamentation, it failed in obtaining a prize through its non-arrival in time for competition; but George Charlton, Esq. (who accompanied Hugh Mason, Esq., and other gentlemen during the evening) was so pleased with the design that he gave it an extra prize equal to the first; that which obtained the second award was in the form of a palm tree, and was very pretty, but not so well arranged as the others. Besides these, there were other designs, amongst which we particularly noticed one in the shape of a proud Peacock, with its extended fiery tail spreading around as though it were alive, and in search of Sol's benignant rays to reflect his light upon it. There were some very good Apples and other fruit exhibited, and specially observable was a plate of Raspberries, grown by Mr. W. Tipping, manager of the mills. They were splendid fruit for this time of the year—or, in fact, any other time. There were also some

splendid Dahlias, some early Crocuses, and numerous other fine specimens of plants, flowers, and vegetables. Indeed, we may say that everything was very good, and the Show being free to the public, it was visited by large numbers during Saturday and Monday. On the evening of the former day a brass band was in attendance, and on that of the latter a party of tonic sol-fa singers were engaged, conducted by Mr. T. Woodcock. The chief prize for Celery was the very handsome sum of £3, given by Mr. Hugh Mason; his father, T. Mason, Esq., also gave a prize, the others being raised by the workpeople. The Judges were Mr. John Moss, Mr. William Worrall, and Mr. John Hague, gardener to Mr. Hugh Mason; and we are glad to learn that their decisions gave the completest satisfaction. We had almost forgot to allude to the fact; but talk about Celery sticks, and there has been a good deal of talk about them lately, why there was one here (not for competition) which weighed upwards of 13 lbs. The show-room was set out and embellished with pictures and banners, and we saw that the reading-room had just received an additional attraction by a large photograph of Hugh Mason, Esq., subscribed for by the workpeople, and forming an appropriate companion ornament to the address lately presented to him. Several of the cottagers had flags floating from their windows, large colours were hoisted above the mills, and everything was done to render Oxford as gay as possible, and not without success either, as the *tout ensemble* clearly demonstrated. It would be well if other large employers of labour would encourage horticultural pursuits, if only for this season, by breaking up some of their land to find their workpeople employment this winter. They might let off pieces as Potato land, which could be turned over during the winter, while the mills are running short time, and be in readiness for cropping in spring. This would be a much better plan than for the male operatives to be walking about with their hands in their pockets, and we trust the suggestion will receive that consideration which its importance demands.

On Saturday, October 12th, the cottage gardeners who competed with Celery, flowers, and fruit, in the reading-rooms connected with the mills, on Saturday, the 14th ult., held a tea-party in honour of the event, when about 200 sat down to an excellent tea and sandwiches, to which they did ample justice. After tea, Mr. John Hague, Hugh Mason, Esq.'s gardener, was called to the chair, in consequence of Mr. Bipping being indisposed.

The Chairman, on rising, said he felt a little flattered by occupying the chair at a tea-meeting of gardeners, their wives, and friends, and was glad to see so many people patronising gardeners. He thought he might congratulate the Oxford Mills' cottage gardeners on the success of their first Floral and Horticultural Show, and hoped to see them next year improving on what they had done so well this. This being a gardeners' festival, he would say a little about gardens and gardeners. Some people made a point of saying that there was no art in gardening. Now, he (the Chairman) supposed that those were the people who took their saucers early in a morning and helped themselves to the cottage gardeners' Onions and Gooseberries; and if he should ever catch one of the people he would be inclined to Lynch law him, and feed him on Onions until he was fairly satisfied. He was glad to see so many cottage gardens in the neighbourhood, for they were good places for the factory-workers to spend their leisure time in, and a little gardening was beneficial in many ways. A garden was a good school in which to learn patience, perseverance, and order, for so that nothing might be done in a hurry. The gardener had to abide by certain laws, which would rarely allow of any exception or breaking. He might learn patience from a common Gooseberry tree, and see something worth the trouble by watching one put forth its tiny leaves in spring, and then see it put forth its bloom; then see its fruit form, and watch it from the size of a pin's head until it became the full-grown ripe fruit; all these things would teach him that Nature performed her great and wondrous works in no hurried manner, but performed all with an unerring certainty. A garden taught patience by the gardener seeing his fruit, flowers, and vegetables, grow better by daily watching and tending them, and protecting them from their enemies, and giving them help in the form of water and manure; or, as he (the Chairman) would call it, giving them food, drink, and clothing. They would learn that nothing could be done without patience; and soon learn that success in gardening as well as in other things, required a deal of perseverance. The commonest over-ermer might teach his children order in a garden; for

if he must be successful he would see that his work must be done at the right time, and everything be in its right place. Weeds should not be allowed to choke the crops; and he could see how much better it was to have good things, which only took up the same room, whether they were in the garden or in the mind. To the factory-worker a garden was a good place for him to resort to in spring and summer, at the end of his day's labour, which was generally very monotonous in its character. In the garden he was brought in contact with Nature, whose pleasing changes and forms never stood still. An essential advantage was gained by the factory-worker in having a garden; he could have nice fresh vegetables, instead of vegetables that have travelled a long way, and were often scarcely fit for human food; and a garden was a good place to pass leisure hours in, now that the hours of labour were shorter than they were in time past, which he, for one, hoped would never come again. Although factory operatives worked less hours than formerly, they would still want something to do; for a man grown up was like a child, he must have something to do, even in his leisure hours, and if he could not do good things he generally did bad ones. He was glad that his worthy employer had given the operatives of Oxford Mills something towards encouraging them to make good use of their leisure hours; and he (the Chairman) should be happy to assist them in their efforts at cultivating the soil. After speaking very highly of professional gardeners, and passing some humorous remarks upon the privileges of gardeners, he sat down amidst loud applause.

The choir (which is mostly composed of the mill hands, and led by Mr. Thomas Woodcock) gave some very choice glees and songs, for which they were deservedly encored; and a number of recitations were given, when votes of thanks, with three times three, were given to the choir, and also to the tea-makers, reciters, and Chairman. The room was then cleared, and a quadrille band introduced, to which the young folks danced right merrily; others played at various games in the reading-room, while a number of the older hands sang and recited for one another in the smoking-room until eleven o'clock, when the company broke up, after having spent a very pleasant evening.—(Ashton Reporter.)

WINDOW CONSERVATORY.

A LADY whose residence will, probably, be at Torquay, will be grateful for information respecting the construction of a conservatory. It is intended to alter and improve the house, and she wishes to know if the sash-windows of the drawing-room and dining-rooms cannot be made available for the front of the proposed conservatory. The situation of the villa is very high and exposed, but as the conservatory will receive very ray of light and gleam of sunshine throughout the day, it is thought that the building will be light enough with broad piers between the front lights. The question she desires to be answered is, How broad might the piers safely be built, and what glass should be used for the roof?

[The piers, pillars, or pilasters, might be from 18 inches to 20 inches, according to the height. If the front of the house was to be 10 feet in height, from 15 inches to 18 inches would be wide enough not to make the house look heavy. However, it would be as well to arrange according to the character of the villa. The sashes may do very well. The roof may be of Hartley's rough patent, and no shading will be required then.]

OVER-VIGOROUS ES-PALIER PEAR TREES—MEALY BUG.

I HAVE two espalier Pear trees in my garden, which from improper pruning have not borne any fruit for several years. Instead of producing fruit-spurs, they have sent out in their place a number of strong wood shoots, which, of course, are perfectly useless. In order, therefore, to bring them into a fruit-bearing state, would it be advisable to cut off the horizontals tolerably close to the main stem, and thus let them send out new wood for future training? or would it be advisable to discard them altogether, and plant a new tree or trees in their place? If the latter, what Pear would you recommend for espalier training?

My pyramidal (Apple-trees) are infested with the mealy bug, Will an application of linseed oil destroy them?—REV. A. K. H.

[If your trees are not shaded by buildings or other trees,

root-pruning would be more likely to improve them than anything else. Certainly if they be healthy they ought not to be destroyed, but if the branches be long and unsightly, it would be advisable in addition to root-pruning to cut the trees down and graft them afresh, when you might have several kinds on one tree, the branches being simply cut off at their base, and grafts put in at the proper time. If your situation be south of the Trent, the following kinds will do in most places:—Marie Louise, Ash-down Park, Winter Nels, Ne Plus Meuris, Glou Moreau, Beurre Diez, Passe Colmar, Duchesse d'Angoulême, and several others. Under any circumstances if the tree has become unsightly, it would be advisable to cut it down and graft it with some of the favourites of the district, adding some others which may be equally good, or better, but not have been tried, and if the soil be wet and sodden, better take the trees up entirely, and raise them above the surface, draining the ground at the same time, as the Pear seems to require a drier soil than any other of our hardy fruits.

Mealy bug is a very difficult affair, the only known remedies for it being also hurtful to the tree, but linsed oil is, perhaps, the least so of any. Rub over the affected parts wherever the insect makes its appearance, and if taken in time with young trees, it will check the pest; but with old, unhealthy trees it is hopeless to restore them to vigour again. It would be better to destroy them and plant others, not in the same place for a year or two, unless you take the trouble of exchanging a cold soil or more of the soil they are grown in for fresh mould. Salt water, turpentine, various chemical substances inimical to animal life, have all been tried to eradicate this pest, but the injuries done to the trees were worse than the effects of the insect itself, that we fear you must patiently watch its progress, and drop a little linsed oil into each place as it appears, and not by any means coat the tree all over with it as a preventive, for in so doing you would seal it up.]

FLOWERING-BULBS IN JANUARY.

In reference to your correspondent "CLERICUS," let me just say that my bulbs, put in a week before this time (October 23rd), last year, began to flower before the end of December, and were in full bloom all January; those in the soup-plates, I mean. They were in a sitting-room, only just above freezing at night in that cold weather.—E. A. M.

VENTILATING A GREENHOUSE—WINTERING GERANIUMS AND FUCHSIAS.

I HAVE a lean-to greenhouse about 18 feet by 12 feet, with a very high pitched roof. The high pitch causes the sliding sashes to run very heavily, and they have remained closed nearly all the summer, the trouble of opening and shutting being so great. The Vines, three in number, have borne well, but are eaten up by red spider, the result, my gardener tells me, of deficient ventilation.

Would a sliding shutter 3 feet by 1 foot 6 inches inserted in the back wall as near the roof ridge as possible, supply the place of the sliding sashes, or be only a useful supplement to them? I cannot put two shutters as another roof would interfere.

I have taken up some of the old bedding Geraniums, potted them, and placed them under the stage of the greenhouse. Will they do there, especially when the house is heated, as it is occasionally, by a hot-air flue? Will that not excite them into growth? How about watering?

May I turn Fuchsias out of flower on their sides under the stage, and withhold water for the winter?—CARDIFF.

[I do not think one shutter will be enough under the circumstances. Instead of cutting your wall why not fix your heavy sashes, and have every other one so much shorter as to have ventilators of 18 inches or so in each alternate sash at the top, which might be hung on pivots to shut and open easily with a string. Your one large shutter in the middle of the back wall might do, if you could open the angular spaces at the ends above the doorways close to the apex of the roof. With plenty of front air on, these two end openings and the shutter in the middle, you may keep all right, and set the red spider at defiance. Without such means half of the sashes at least, or ventilators in them, should open at the ridge.

See "Doings of the Last Week," as respects Geraniums. If

watered now they will need little more before spring. We presume you have taken off the leaves.

The Fuchsias if to have no water will do better standing, instead of the pots being laid on their sides under the stage, as in the former place they will absorb moisture sufficient from the ground. If you must lay them down, you had better water them previously, and if pots are placed above pots, cover them over with moss to keep them from getting too dry.]

MYRTLE INJURED LAST WINTER.

WILL you inform me of the best method of treating a Myrtle under the following circumstances?—It is 12 feet or 14 feet in height, against a wall due south. It has hitherto remained out all the winter without any protection; but last winter the frost injured it very much, and, consequently, in May I had not only the dead wood cut out, but the tree was lightened of a considerable quantity of its healthy wood, but being unwilling to diminish the height, I left the wood at the back. This summer it has come out vigorously where it was cut, but the other wood, though perfectly healthy in appearance, produced yellowish, sickly foliage. This autumn it has gradually assumed a more healthy hue, still it is unlike the vigorous bottom shoots. Under these circumstances would you defend it carefully from severe frost this winter, in the hope of its coming out healthy in the spring, or would you reluctantly sacrifice the growth of years, and reduce the tree to a common shrub?

[Touch not a leaf of that beautiful Myrtle till the end of next April. Then, or when the new growth of 1862 is just 1 inch long, stop every one of the new shoots or new growth of this season near the bottom, and do not allow any part of the bottom to grow higher than where you stopped till the top of the plant is in full vigour again, if it were not so for the next two years. But you may expect to see the balance of power between the top and bottom restored by next August. We have done the very thing more than once, and we saw a favourite Myrtle sacrificed this last summer for not doing it. Sometimes a very strong shoot breaks from a dry part of the top shoots, a robber as they call it, that you must not allow, but stop it at 6 inches or 9 inches, so as to equalise as much as possible the fresh growth all over the top part of the plant.]

EDGING MATERIALS FOR WALKS.

FOR the information of any of your readers able to procure it, the "Kerridge," or self-faced flagstone, of course set on edge, makes a firm, durable, and neat border.

I have this year laid down a quantity procured at Cooke's quarry, Bollington, near Macclesfield, which cost, delivered by canal 120 miles from the quarry, 6d. per yard. It is sent dressed on the edge and jointed; and in lengths of 1 foot to 4 feet, by 9 inches to 12 inches, by about 1½ inch.—K.

A FEW DAYS IN IRELAND.—No. 3.

THE VICEREGAL LODGE, PHOENIX PARK.

THERE is little of the magnificently royal in the outside of the unpretending, modest-looking building appropriated as the residence of the representative of Majesty in Ireland. We have been assured, however, that the internal arrangements are sufficiently capacious and suitable, to have met the requirements of the many celebrated noblemen who in turn have occupied the position of Lord Lieutenant. Shut in from the bustle of the external world, embowered in trees and shrubs, it seems just such a place as poets and philosophers might long for, if permitted to long at all, and no doubt by its very quietness has helped to soothe down many a heart wearied and distracted by the turbulence, the anxieties, and the cares of political life. There seems to be something peculiarly fitting, that such a lovely spot should now be occupied by the Right Hon. the Earl of Carlisle, not more known for his patriotism than for his liberal benevolence and true warmheartedness. Now, when the political strife and deadly enmities of bigoted partisanship are fast dying out, never again it is hoped to be aroused into action, and when a neighbour as he meets neighbour, and sees so many that is worthy of his respect, wonders he could not see it all before as well as now, just because he could not perceive that other men were as

anxious as himself to secure the public good, though the means adopted might not be exactly identical. More of the "charity that thinketh no evil," would be exemplified, when we act on the fact, that the same goal may be reached by many a different route.

The garden front has more of the dignified, but in unison with the dignity the chief features are—completeness, quietness, and repose. The dignity is chiefly secured by a broad terrace of gravel and grass, extending as far as the garden front of the mansion. This terrace is some 3 feet above the level of the flower garden, in front and on each side. A broad walk of the same width as the gravel on the terrace, with stone steps at each side, runs the whole length of the flower garden. The walk on one side going on to a cricket ground, shrubbery, Pines, &c., and on the other side next the kitchen garden, after passing the boundary balustrade, opening to a walk, narrower, though still wide, extending in a straight line 370 yards, and adorned on each side at regular intervals with plants as regular in outline of fine-grown, healthy Irish Yews. The middle of the mansion acts as the measure for dividing the flower garden in two by a wide gravel walk, with suitable steps at the incline. A fine dial in the centre of that walk, and steps again at the extremity to take you up to a narrower terrace bounded by the balustrade and vases. The accompanying section will show this, and also

how such terraces, and the simplicity in the details, give a dignity to the garden front of the mansion. (See the plan of half the garden). Be pleased to notice how the fine Irish Yews are placed at regular intervals at the sides of the walks.

Then the first sight of the garden, even without going over it, which we did not do, shows its completeness in itself. The straight lines in such a position, the dividing it into two equal parts, and the boundary balustrade make all this manifest. No mere scattering of beds in front of a mansion or anywhere else, will ever produce such a feeling of unity and wholeness. Where the position will admit of it, a flower garden near a house will never suffer from a clearly-defined boundary. There is no chance, then, of a good plan being spoiled by one man making a few more flower-beds here, and sticking in some more shrubs and trees there, just because he has taken a fancy to do so. Perhaps, the idea of completeness in connection with seclusion and quiet, may have been carried too far, as we noted the tops of young trees planted outside rising above the line of the balustrade. There might be good reasons for this, which we neglected to see. There were plenty of openings to admit the beautiful surrounding scenery in the Park and beyond, and there might be a reason for concealing the wall from the outside, more potent than hiding anything outside from the inside; but even then the trees should not be too near the wall, nor be prominent features from the terrace, unless objects really worth looking at.

What pleased us most of all, was the seeming quiet seclusion of the mansion so nicely carried out in the feelings of rest and repose excited by the garden itself. How distracting to the mind already jaded with care, to stand on either of these terraces and see the whole space a mass of gorgeous colour with hardly space enough between the beds for the one to be distinguished from the other. In some positions this would not be so undesirable, but here we think such an arrangement would have been wholly out of place. The great charm of this garden is the breadths of fine green turf for the eye to rest upon. Not but when we saw it in the middle of September, there were not abundance of flowers. The parallelogram-beds next the walks

PLAN OF THE FLOWER GARDEN AT THE VICEREGAL LODGE, PHENIX PARK.

The small circles mark where upright Yews are planted.

were beautifully in bloom, generally two or three colours, or more, in each bed, and the circular group in the centre was equally well filled. The very simplicity of the arrangement,

united with the open spaces of turf, gave a charming effect to the whole, and would teach a lesson to those friends who must have a bed placed in every possible open space. Perhaps it

might have lessened the simplicity, if the parallelogram-beds had been shorter, curved inwards at the ends, and a circle placed between every two; but it would have admitted of more variety in outline, and more variety not in planting merely, but in the style and manner of planting, as even level masses of colour, however beautiful, if appearing all of the same height, become monotonous to the eye. The upright Irish Yews so far prevented this drawback.

The useful garden is large, we forgot how many acres, well surrounded, and we think divided by walls into three unequal divisions. The lesser of these contains what may be termed the Melon ground, pits, small houses, and ground for standing plants in summer, and the residence of Mr. Smith, the much-respected gardener, with whom we had not been five minutes without experiencing not only that we had made a new friend, but one with whom we could use the familiarity and freedom of an old one. Some business arrangements prevented us getting as much information and that comparison of ideas, at all times so pleasing, as we could have wished. As we have been dwelling upon flower-gardening matters, we may here state, that if bedding plants were planted in the flower garden in hundreds, they must in the kitchen garden have been turned out in thousands. The sides of the main walks were thus rendered ornamental, showing not only the love for such flowers in masses, but that there was plenty of room to spare besides for the useful as respects the kitchen and the dessert table.

The entrance from the Melon-ground quarter to the larger garden showed a fine range of glass houses 400 feet long, with wide borders, and the front of the border a straight-lined ribbon. A broad ribbon occupied the other side of the walk much longer than the range of houses. On your right hand as you entered, in front of a wall of healthy Apricot trees, was another ribbon, and the opposite side of the walk was planted in a similar manner. The plants in front of the Apricot-border were all naturally low, or made so by nipping and pinching, and a good space next the wall was left unplanted. There were five rows beginning at the Box edging, white Variegated Alyssum; *Gazania splendens*, fine; Purple Spinach, of Henderson's, pinched down; *Tropæolum Stamfordianum*, dwarf and full of bloom, though with us it grows too strong; and seedling *Cineraria maritima* for the back row, showing the same grey instead of silvery appearance as they have done with us, as mentioned a short time ago. The other side permitted of taller plants at the back.

Then of the long wide border 15 feet, opposite that in the front of the houses, the back row was a dense mass of Sweet Peas, then Hollyhocks in good bloom, followed by distinct rows of *Ageratum*, white *Verbenas*, Scarlet *Geraniums*, Purple King *Verbena*, Bijou Variegated *Geranium*, *Beauté de Paris Verbena*, a bluish-grey, *Mangles' Variegated Geranium*, and *Cerastium tomentosum* next the Box and gravel. We forgot how many rows were on the borders in front of the houses, but they did not occupy above half the width, and beginning with *Cerastium* next the Box, the rows were confined to plants of low growth, and similar to the opposite side, as far as they went. For ourselves, though the one border would not have been so striking without the other, we do not think that such borders in front of houses are to be recommended, unless at the very front, and that not so much because the plants starve the border, as because they keep the sun and atmosphere from acting on it. The rows were farther apart than we are in the habit of planting them, and, therefore, every row was clear and distinct from end to end.

We now return to the Melon ground, having disposed of bedding plants before going farther, to have another look at a quantity of splendid *Chrysanthemum* plants plunged in ashes to save watering, which took our eye on entering the garden-door. Many of these plants were in 24 and 16-sized pots set inside larger ones, and then plunged, and ranged from 3 feet to 4 feet, and even more across, bristling with shoots all over just knotting for bloom, and many of the widest plants were not much more than 1 foot above the rim of the pot. These plants were chiefly struck in the early autumn of the previous year, were potted and grown on slowly all the winter, getting stopping as they required it, received their last potting early in summer, and were regulated and stopped until the beginning of July. The training is effected by two rods of wood laid at right angles across the pot, and as far beyond as the shoots are expected to reach. These rods are securely fastened to the rim of the pot by a string or wire below the rim, and a smaller wire binding the rods and the wire together. A stout wire forming a circle is fastened to the four ends and the frame is complete. If the

circle is large—say 3 feet, or more, in diameter, a ring or two more of wire divides the space inside. To such frame the main shoots are tied as they grow, and then the upright flowering-stems need no sticks whatever, only a little arranging with threads to keep them regular. The plants are kept rounded in the centre to give them a graceful outline. Of course such plants are liberally nourished.

Besides great quantities of such plants as Chinese-*Primulas*, *Cinerarias* out of doors, and in cold pits, in the heated pits and houses, there were fine plants of *Thysanotus rutilans*, *Euphorbia jacinthiflora*, *Poinsettia pulcherrima*, *Justicias*, of sorts, and other things for winter blooming, and a very plain and serviceable low-spaced house appropriated to Cucumbers and Melons trained to a trellis about 15 inches from the glass. The beds on each side were heated by hot-water pipes below them. There were upright pipes for letting up damp heat as required, but chiefly for giving moisture to the roots, and there were pipes through the bed, near the pathway, communicating with openings outside, so that the air so admitted should be heated before rising into the house. The chief peculiarity, however, and one involving economy of fuel, was that the flue from the boiler runs beneath the pathway in the centre, and the flue being strongly built, and covered with strong tiles raised on the edges, so as to hold water, there was never any want of a moist atmospheric heat. This only proves what we have often stated, that the proprietors of small places may go to large places, even regal ones, to learn economy in management.

The fine range of houses in the large garden are curvilinear. A great change and improvement is being gradually carried out. Formerly they were only 11 feet wide, and there not being too much ventilation at the top, we should judge that the heat must at times have been excessive. They are now being enlarged to 17 feet in width, by taking the back wall farther back, leaving the first roof as it is, supported on pillars, and connecting it with the new back wall by a hipped glazed roof, from which abundance of air can be given, and also space afforded for cultivating many things against the back wall, with a good share of light coming to them.

One of these houses was filled with fine, healthy, well-grown *Pelargoniums*, designed to bloom early in spring, and that without anything worthy of the name of forcing. The plants had been struck in 1860, potted in spring, stopped as needed, no flowers allowed, and now they are nice bushy plants some 30 inches in diameter, with shoots of equal strength all over, that will ere long knot for flower-buds. Another house called the *Geranium-house*, was filled with large and older plants, perfect pictures of symmetry, now not much more than 1 foot in height above the pot, and from 3 feet to 4 feet in diameter at the base, trained exactly as stated above for the *Chrysanthemum*. Many of these had been cut down last August, or rather pruned back, have been grown on slowly ever since, no flowers allowed to come, and now they are well regulated with stout shoots of about equal strength, and will bloom in May and June of next year, when we were assured they would be fully 5 feet in diameter at the base. These and those at the Chief Secretary's, were the best plants, we think, we have ever seen. It will not be forgotten, however, that the best part of two years is bestowed on getting them to the flowering state. As soon as a young plant is struck, potted off and stopped, the training commences. Many gardeners have told us how splendid these, and those treated much the same way at the Chief Secretary's, look when in bloom, and no stake and hardly a tie is perceptible.

There is a house also devoted to hardwooded plants, as *Acacias*, *Heaths*, *Eperisies*, and many other things, promising abundance of bloom. The workmen were engaged with others from which the fruit had been removed. In one late house there were some nice Black Hamburg Grapes, and in another a heavy crop of Muscats just changing colour, and getting yellow. In one viney 70 feet long, a Vine planted in a corner at one end inside was destined to fill the house. There had been several plants, as *Heliotropes*, and other things planted close to the end of the house. Mr. Smith thinking the Grape (Black Hamburg) better than usual, had these plants all cleared away, and as good loam, &c., as he could get put about the roots, and the branches of

A, A, A, A, the four ends of the two crossed sticks. Centre circle-pot to which stakes are fastened. Two outside circles wire forming the training-frame.

the Vine divided and trained so as to grow longitudinally along the house some 2 feet apart. It has been spur-pruned. It already occupies more than two-thirds of the house, and the young wood at the point of every spurred stem is not only strong, but very equal in strength, short-jointed, and the buds bold and rounded, showing that the Vine will shortly fill the house. The bunches were regular, and of a good size, but slightly tarnished, here and there, from being syringed with water that had left a little sediment. Many to avoid this, never syringe at all after the Vines are in bloom. The flavour was delicious, but we could not say it was thoroughly distinct in this respect without tasting other varieties at the same time. Without this is done we have no faith in the dictum, "Never tasted anything so nice." The houses were heated by pipes on the level. The flue from the boiler was also used.

In what we may call the second garden there was a range of glass in several divisions 250 feet long. There was here an early vine just pruned, the wood looking nice, and three Peach-houses, from which the fruit had been all gathered, but the wood showing that a heavy crop had been obtained, and the wood in the best possible condition, ripe and ripening, neither too strong nor too weak. These Peach-houses 13 feet wide and 12 feet in height at the back, had the trees trained up 16 inches from the glass, and few plans answer better, and none is more simple.

In front of these houses two large quarters were devoted to dwarf and pyramidal trees of Peas, Apples, Cherries, &c. Dwarf trees round the walks, especially young ones, had grown so well that Mr. Smith contemplated raising and planting again to check their vigour. The walls were well supplied with trees, and most of them, especially the Peaches, showed signs of ripening their wood kindly. Fruit of all kinds, except early small fruit, was scarce this season. The Strawberries in beds, and also in pots, were looking strong for next season. We suspect a great number of Strawberries are forced every season. The Strawberry-pots were plunged in the ground.

We may just add, in conclusion, that those cannot be done without things—vegetables—were in great plenty and good condition. We forgot it as Asparagus; but there are many places in which this will not grow, though it flourished some twelve or fifteen years ago. Among other things extra good were late Peas, and especially Hair's Mammoth Pea, true, which was very fine, with not a sign of mildew about it. The grand secret, Mr. Smith told me, was manuring with rotten dung as heavily as for a Celery-bed. We expect it will bear until the frost cuts it down. R. Fish.

GROUND OR EARTH-NUT.

CAN the Editors inform me what the little bi-lobed plant is that school-boys call the Ground-nut, and which they dig up with their knives and eat in large quantities? It formerly was found in Rutlandshire. I wish to obtain a supply for experimental purposes. If any information could be kindly furnished me where it is probable it may be obtained, I shall esteem the favour. It is not the *Orchis mascula*, which, I believe, was formerly used for saley. If I remember, the plant had a small white flower. Could it be the *Saxifraga granulata*?—M. D.

[It is *Bunium dendudatum*, sometimes called the *B. flavosum* and *B. bulbocastanum*. It has many English names—viz., Earth-nut, Pig-nut, Ar-nut, Kepper-nut, Hawk-nut, Jur-nut, Earth Chestnut, and Ground-nut. Swine are very fond of these tubers, and fatten upon them. They are pleasant tasted when boiled or roasted, being superior in flavour to Chestnuts. They are cooked in soups in Holland, the Alps, and many places in this country, and are said to be very nutritious. We shall be obliged by any of our readers sending us some of these tubers, which we would forward to our correspondent.]

PINE APPLES DECAYED IN THE CENTRE.

HAVING lately cut about three dozen beautiful-looking Pines, in a small pit attached to several others for the cultivation of Pines, to my great disappointment these Pines when cut are nearly all black in the core. They were grown in pots; soil used, three-quarters tuff loam, to one-quarter peat, with a little charcoal mixed. The pot is fibry and full of fern roots. The pits are heated with hot-water pipes top and bottom. The bottom heat has been kept at 90° to 95°, the top heat 80° to 95°

by day, and 65° to 70° by night. Every attention has been devoted to air-giving, watering, and syringing. Water is withheld altogether the moment the fruit begins to change colour. They had a little weak guano water once a week when the fruit was swelling. I have grown Pines somewhat extensively for several years, but never was so unfortunate with them before. I shall be particularly obliged if you can tell me the reason why they turn black in the centre, and suggest a remedy. Nothing could have looked better than these Pines when swelling and colouring?—DEVONSHIRE.

[We once had a case somewhat similar, and attributed the defect to keeping the plants too moist at the roots, and in too moist an atmosphere to swell the pips to the greatest size. In another case, to give fine flavour, we kept the roots dry and the atmosphere more moist than it should have been, and the centre was a brownish colour and dry.

We by no means would state that either of those treatments was the cause of the decayed centres in the present case, as we have heard of the inquirer as a first-rate Pine grower, but we merely mention our experience and hope that our coadjutors and readers will be able to give a more decided reason for this very great annoyance and disappointment.]

BOUQUET OF FOLIAGE.

At this dull time of the floral year, few are the flowers that can grace our vases; but empty vases are the gloomiest of things, and I think the readers of THE JOURNAL OF HORTICULTURE will like to have a hint of a way which I have often found very useful, as to how to fill them.

I have a vase before me at this present moment, which looks as light and graceful as I could wish to see, and all its contents are half a dozen leaves!

Everybody knows the magnificent foliaged plants introduced so largely by the Messrs. Veitch. A few days ago I wanted some pretty plants, and these gentlemen very kindly sent me up some "patterns"—that is to say, cut leaves of several Ferns and flowers. The flowers, gay as they were, I left to fade unheeded; for the leaves alone made so exquisite a group as was enough to charm the most genuine lover of beautiful shapes and colours.

There are three kinds of Ferns—one, with a silvery vein; another upright-leaved one having moning beautifully with the paler green; another of the exquisite *Pteris tricolor*, with its lilac veins; and then a *Caladium* veined with crimson and dotted about with white. Two dark, coppery *Begonia* leaves are added; but whether they are improvements I can hardly say. Faithful to my principles as to Ferns and Heaths, three or four sprays of a small pink Heath peep up amid the Fern, and give a little height. From my own stock I added one frond of *Davallia* (*D. canariensis*), I purchased as a small plant some months ago from Messrs. Hooper's stock, and potted directly into cocoa-nut fibre refuse, which makes all Ferns grow so luxuriantly and well; and one frond of *Adiantum formosum* waves gracefully above all.

This is so simple and so easy a plan for filling empty vases, that I am sure your readers will like to try it. My vase is just 12 inches high, and about 5 inches wide across the spreading lip.—E. A. M.

SHAKSPEARE'S GARDEN.

THE following letter to the Rev. G. Granville, Vicar of Stratford-upon-Avon, is so interesting to the lovers of Shakspeare, that we have no hesitation whatever, in placing it before our readers:

"24, Essex Street, Strand, Sept. 13, 1861.
 "Dear Sir,—I read in the *Athenaeum* in the spring of what you were doing for the Home of Shakspeare; as the trees which the Committee had already planted, and of what they hoped for. It was said, 'a fine Fig tree is climbing up the west wall and will give us green Figs in time'; and it was asked, 'who will give to Shakspeare a hardy Vine, one that will bear the "purple grapes"?' This house is built upon part of the substructure of Essex House. The two lower stories have the old thick walls. The garden is where the old terrace once was; 20 feet and more above the adjoining Temple Garden. Under it is a long lofty vault, and in it are two old Vines. I do not pretend that they are as old as Elizabeth's time; but I have a fond hope that if it are-storied 'ivy gave grateful treble shade, as one of them does now. Their roots are somewhere, no doubt; the old mortar in the vaulting must be very good to give such fruit. Now, my fancy is so romantic as to believe that Shakspeare must have many a time walked up and down the bit of terrace; have sat at the end with my Lord Essex and Lord Southampton, admiring the moonlight and the river or jostling with 'Night's' tempters over the parapet wall; must have drunk some sack in the cellar, and taken water at 'the stairs.'

It is even believed that hardly at Stratford is there anything so little altered and so near to Shakespeare's footsteps as our paved garden: hence my writing, that the year before last I reared a Vine by bending down a shoot from the oldest one; that it is well rooted now, and though this season and the last have been unfavourable it is in excellent health; and that, if it so please you and the other members of the Committee, the autumn being come, I would have it taken up and carefully packed, and sent at the proper time for transplanting in its 'New Place.' I am not unused to Vines; I think that very soon it would 'bear the purple Grapes.'—I am your obedient servant,
"JOHN J. COLE."

Of course the Vicar and the Birthplace Committee very gladly accept of the appropriate present. We hope the plant may thrive. —(Athenæum.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE late beautiful weather has, I hope, been embraced for carrying out all matters previously directed. Perseverance must still be continued in the way of hoeing, forking, and surface stirring amongst growing crops, particularly Coleworts, Cabbage, late Savoys, and Kale, as a regular demand for things of this description may be expected throughout the season, and more especially in the spring. Beans, a few Mazagans may be planted in soils favourable to vegetation during winter, either where they are to remain, or on a sheltered border, for planting out early in the spring. Cabbage, vacancies in the main plantations to be filled up immediately. Employ lime or soot about young Cabbage and Lettuce plants, and repair rages from slugs. Carrots, the whole of the principal crops to be taken up and allowed to dry before they are stored away in sand. Cauliflowers, those in frames and under hand-glasses to be divested of their dead leaves, and if any vacancies occur they should be filled up. Give air freely every fine day. Celery, if severe frost should set in some long litter should be laid over the most forward crops. Endive, when quite dry, tie up a good quantity for blanching. Onions, the autumn sowings to be hand-weeded, and the ground slightly hoed between them. Peas, in very dry favourable situations the first sowing may now be made. Shallots and Garlic may now be planted in light, dry soils; but where the ground is heavy it is better to postpone the planting to February. It is advisable to observe particularly if there are any fresh-used mouse holes, if any should be discovered at once get some water and begin pouring it hastily into the hole, which will soon start the inmates, when a flat bushy bough, if used expertly, will soon put an end to all fears about their attacks when the Pea-sowing season arrives.

FLOWER GARDEN.

It is advisable to go over the standard Roses, and to shorten all the very long shoots, that the power of the winds may be considerably lessened when beating on their heads. Chrysanthemums against walls to have their shoots closely tacked to them, and some slight protection to be in readiness in case of an unexpected frost. If any of the biennials are still unplanted let them be planted out now in the places where they are to bloom. Pansies may be divided and planted out for next summer's bloom. The sooner the Tulips are planted the better; when the bulbs begin to elongate the leaf-spike the roots are taking harm. Wherever alterations are in progress lose no time in completing the transplanting of evergreens, the present mild, damp weather being favourable for their removal. Be careful to secure transplanted things against wind, especially large plants, which should never be left until they are properly staked or otherwise made fast; for where this is neglected or postponed it frequently happens that the roots get injured through the tops being rocked about by the winds. As soon as the greater part of the leaves are off the trees let the pleasure-ground be thoroughly cleaned and swept; the leaves, if abundant, to be stacked up for forcing purposes, covering borders, &c.; and in small places to be swept into a hole to rot into leaf mould. The part near the house to be swept daily, to r-move leaves and worm casts; and the gravel walks to be frequently rolled, to preserve a smooth surface. As the re-arrangement of the herbaceous ground is considered necessary every two or three years on account of the free-growing plants getting too large, the present is a good time for doing so.

FRUIT GARDEN.

Look over all kinds of stored fruit occasionally, sort out the affected, and wipe others when required with a dry cloth. The out-door Vines to be gone over, and all the lateral shoots that may have been left to the strong shoots to be taken off, and two

or three of the joints of all the young wood at once pruned off, which will be the means of greatly facilitating the maturation of the wood. Look over the trees in old orchards, and remove at once those that are considered worthless or worn out. Prepare some good soil for planting other varieties. Prepare ground for new plantations of Currants and Gooseberries. Cuttings of favourite sorts may now be made and planted.

STOVE.

The weather has been most favourable for ripening the succulent shoots of free-growing plants, and, therefore, they may be expected to get well through the winter. The temperature may now decline at night to 60°.

GREENHOUSE AND CONSERVATORY.

On all favourable occasions admit air freely; it will not produce those withering effects that such an exposure would do in spring. The plants having been recently fully exposed to shut them up close now would induce growth, and produce ruin. Pelargoniums will now require some care; watering to be given in the morning, and when there is any appearance of ill health from a foggy moist atmosphere they would be benefited by a little fire applied with abundance of air to drive off the damp; the plants to be placed pretty close to the glass; the principal shoots to be pegged out at regular distances, and the useless ones removed. Cinerarias intended to flower as specimens in spring should now receive their final shift.

FITS AND FRAMES.

Neapolitan Violets to have as much air as possible, and the runners to be removed as they appear. Intermediate, Brompton, and Ten-week Stocks intended for next year to be kept dry, and air to be freely admitted to prevent damp. See that everything is now stored for winter, and give air most abundantly while the weather is fine. Stop Verbenas and other such free-growing plants as they advance, in order to render them busily, and water them occasionally but very carefully. The lights to be on during wet weather, but tilted up at the back. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

SOWED a row in fine prepared soil of the Parsnip Cervil (*Cherophyllum bulbosum*) recommended by Messrs. Vilmorin, Andrieux, & Co. Earthed-up Cabbages to keep the stems secure if severe frost should come. Never knew Cabbages and Turnips grow as this season, dry weather and all together. A fine shower on the 22nd, which will help to fill tanks in this neighbourhood that have been next to empty. Laid down in an earthen pit the stems of Cauliflower now beginning to button, to which we will give a little protection when needed. Went over the Cauliflowers showing heads on border, broke a leaf or two and laid over them, which will protect the heads from rain and throw past them a few degrees of frost. Took up all but the last sowings of Carrots, Beetroot, &c., as the latter is best never to see much frost. Gathered the last of the Tomatoes, which have been going a-begging this season; and dug, or rather trenched, part of Carrot ground, in order to put out a good piece of younger Cabbages in case the first should be too forward to stand the frost well, as the want of Cabbages in spring is almost as bad as the want of Parsley, and that was scarce enough in some places last year. Cleared off spent pea haulm, the latter ones being still pretty good; and collected seed of *Scutell Ranera*, which will be good this season and no mistake. If I had not obtained plants from a neighbouring farmer I should have been rather pressed—my own seed, and that from an eminent seedman, alike refusing to grow more than something like one in six. I do not know what quantity our neighbour sowed in a b-d. He said the seed was from two to three years old; but the bed was as thick as the plants could stand, and there was no want of applicants until it was thinned sufficiently. I believe our friend was downright sorry when being able over coming to his bed, there is such a pleasure in people giving to oblige. Swept over *Mushroom-beds*, put droppings in sheds for successions, and removed the spawn from the heap as it matured, as there may be month's difference in the bricks being thoroughly spawned through. The spawn should be kept in a dry place, where it will keep good for years. I cannot well say for how many, and therefore, if a dealer has some good old spawn, there is no use waiting until his fresh

made of the season comes in. I have used it with good results four and five years old, and I am not sure but that Mr. Judd, of Althorpe, has used it older still. It is as well, however, not to use it too old, unless extra well kept, for if exposed to damp, or allowed to get too warm, I would not give much for it. When matured the spawn should be permeated with the white streaks smaller than the finest hairs; if as large as small threads of cotton, it may do for present use, but it is too far advanced for keeping. Blanched Endive, by placing a tile or a slate over the tops, and moved some to earth-pits, where protection could be given more easily as wanted.

Dusted charred rubbish among young Cauliflowers, Lettuces, and all young things whatever, that the slugs might be apt to nibble, and sent boys round the walks to pick all they could find of the slimy fraternity in a damp or dewy morning. The black-backed yellow-bellied chaps so difficult to kill, are fond of getting on a hard walk at such times, and also of getting round and upon a handful of brewer's grains.

FRUIT GARDEN.

Much the same as last week. Brushed a few more leaves off the fruit trees, and prepared for fresh planting. Now and for a fortnight or three weeks to come, is the best time for planting all sorts of fruit trees, and also a good time for planting forest trees, as though the leaves be still on the trees they will not be injured now, and the roots begin to run into the warm soil before winter. Evergreens may also now be moved with half the trouble they will require in spring.

GREENHOUSE, &c.

The greenhouse being thoroughly cleaned has been refilled with *Camelias*, *Azaleas*, &c., and means taken for filling all the spaces beneath the stages with plants, such as *Fuchsias*, and old *Scarlet Geraniums*, that require little light and less water in winter. All places under glass will now go through a cleaning process, and to be followed by a cramming process. Properly speaking, in most cases, this would be wrong, as plants under glass in winter, in a growing condition, require more room than in winter, owing to the light being so deficient; but, then, when we cram so much we keep down the temperature to the living-point in opposition to the growing state, and when we let growth take its way as the days lengthen in March, we can turn a good many under protection out of doors. A pit containing some decayed leaf-mould was turned over, 15 inches of drishy dung, a little warm, placed beneath it, and the leaf mould on the top, and on this leaf mould the Golden Chain and Alma are being plunged after being up for a week, the most of the leaves being removed, the best plants squeezed into 60-sized pots, and smaller ones, four or five, into a 48-pot. The little heat at the bottom will encourage a few fresh roots before winter. The tops will be kept cool by air. We do not want these to break much before March. Alma, and a few other variegated ones, will be treated the same way. We shall take up some others, and pack them closely in boxes, or in good-sized pots, and try and get them under stages or into sheds where frost and damp will be excluded. Have pricked out a border of *Cerastium tomentosum* and Variegated Arabis a few inches apart, using little bits so as to form them in rows, with a little sand put in. I have no doubt they will be nice plants by April. The beds in the flower garden are so little disturbed that we can do nothing with them as yet. *Scarlet Geraniums* are as fine as ever they were. The variegated ones are about over.—R. F.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to the Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E. C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

PLAN OF GREENHOUSE (A Country Curate).—See pages 79 and 71 as to

tank-heating. Your mode of dividing the house is good. Glass will be best, at least above the stage in the front. The other part may be what you deem best. Whatever may be your mode of division you should have openings in it to shut and open at pleasure; otherwise we fear if you have merely a tank along the south end, and not also along the west side, you will not have heat enough in the colder greenhouse part. With openings in front the propagating-house in severe weather you may do very well. In such circumstances we prefer the plan to the lead-to. Your having glass to the ground on the west side will require more heat in severe weather. The plants close to the south end will draw that way unless you reverse and turn them round frequently, but the tank will face the west not afterwards.

FRUIT TREES FOR A VINEY (Berks).—We do not advise you to put Plums in the house if you use it to force at all; but Figs would do admirably in the warmest end, and Apicots in the coldest. If you could give abundance of air there, you might try Coe's Golden Drop Plum. Both these and the Apicots will have plenty of air. When in fruit and in severe weather, shine a little shade over the sides of the house, but it would be better if you may grow in pots and plant out, so as you can get at the roots when the plants grow too freely.

ENGRAVINGS OF FRUITS (A Subscriber).—There is no modern work like that of B. Langley's "Pomona," published in 1723. The only recent portraits of fruits are coloured, and are in various works, such as the Horticultural Society's "Transactions," the American Agriculturist's "Horticultural Garden," Bonaldi's "Pyramus Mains Brontfortiensis," Hooker's "Pomona Londinensis," and Brook-hav's "Pomona Britannica."

WORK ON PRUNING (A Subscriber).—There is no work devoted to the subject. Our "Fruit Manual for the Many" contains an epitome of the modes of pruning all hardy fruit trees. You may have it direct from our office for five shillings.

NAMES OF FLORA (Flora).—Your Apple is King of the Pippins.

DESA GRANDIÆRIA (Flora).—You had no just excuse for writing to Mr. Leach on the subject. That gentleman gave the entire stock of it to the Gardeners' Benevolent Society, the money the plants sold for to be added to the Society's funds. I have never heard what the stock sold for, nor who bought it; nor had Mr. Leach heard a short time ago. Perhaps the Secretary has since informed him.

WAXING GERANIUMS (G. L.).—The best way to keep *Scarlet Geraniums* in winter is to cut them down and burn, and brush like *Delarganiums* in October, and then give them six weeks' or two months' bottom heat; that is most certainly the best plan. Then it must follow that most of the small fibres are cut out. But when they, the plants, must be dried and go into casks and similar places, the small fibres would most certainly die of themselves, just like the fibres in Mr. Rivers' orchard-house trees, and it is as certain that it would be best to part with them at once.

PRUNING ROSES (Ilem).—The very weak and the very strong wood of all Roses, without exception of kinds, should be pruned in July, not in October or November. After the first flush of summer bloom is over every Rose ought to be pruned, which means that the main pruning of Curran's and Gosselbergs. The very weak wood of all Roses ought to be cut out at the end of October; and all the unkindly and weak Roses you see here and there on the top of fiddlestick stems and called standards ought to have their annual winter pruning before October has passed. All moderate Roses should be pruned in January, and the very strong in March. The reasons for the differences will be found amply detailed in former volumes. We are glad to have queries from you, or from any other correspondent, every week, but only two or three questions at a time, so that each enquiry may have due attention.

TAKING A SMALL FARM (Farming Adventure).—It is difficult to give advice in your case in the absence of all knowledge of the locality you propose to settle in; but assuming it to be in the environs of some large town there seems no reason to doubt of your success. At the same time you must prepare yourself for many difficulties and some few disappointments, but with a determined perseverance to succeed there is little doubt but you will ultimately do so. We think, however, that less than six acres will suffice if you purpose to cultivate it by hand labour, which is the best way to make expensive land pay, and in the neighbourhood of a town you will find it very dear. A friend of ours similarly circumstanced as you, started a small nursery or market garden a few miles out of Liverpool, and he had to pay an almost fabulous price for the plot of land he wanted, and he is doing well. All, however, depends on the prosperity of the district. If you have some knowledge of gardening you might erect some glass structure to produce Grapes or other fruits that would pay well, or you might turn your attention that way and send some for your neighbours to see, being an increased demand for such things. At all events, before you embark in an undertaking of which you are not most intimately acquainted, it would be advisable to look well around you, and consult others similarly situated to what you wish to be, making, of course, allowance for any prejudicial opinion that may be given. Having given this general advice, we will be glad to answer you on three questions. 1. Six acres of land, if good and within six miles of a town of 100,000 inhabitants, would in all probability cost £500, and more if there were buildings upon it; and indifferent land is dear at any price for hand labour. 2. The neighbourhood of a town would most probably be the best for such an undertaking as affording the best market produce. 3. If cultivated by hand, less than six acres ought to occupy both you and all your family. So much, however, depends on the character of the cultivation, market garden crops following each other in quick succession requiring much labour. Fruit orchards, less, excepting in the fruit season, and then the increased employment for all. But above all, do not settle down in a bleak ungenial neighbourhood; for although you may succeed even then, you will find it uphill work. In conclusion, we advise you to read carefully the directions given for cropping, &c., in the Two-Acre Farm, and also in the subsequent articles in that way in THE JOURNAL OF HORTICULTURE.

FLOWERS IN BOUTIERS, &c. (A. L. M.).—The communications on this subject which have appeared with the signature "E.," will shortly be published in the form of a small volume.

FLOWER-GARDEN PLAN (C. A.).—The planting is very good indeed. We never offer an objection to any plant or plants any one may choose, providing the colours come near the truth; and there is not much discrepancy between plants which are matched in pairs, or planted the one with the other.

ARCHBISHOP MACRINE.—"T. P." wishes to know where he can obtain one. Any machinist advertising them would find our customers.

ASPHALTE WALKS (*Miltonianis*).—We know that the asphalt walks do not injure trees or plants growing in the adjoining borders, nor do they injure the grass of a lawn which they bound; nor do we think they would injure the soil, unless the tar was allowed to run among it, which might be easily prevented by a board placed before it, while the asphalt was being laid down.

PROPERTIES OF A GREENHOUSE (*Quid Prodest*).—For such a house 18 feet long, 9 feet wide, the height at back might be 10 feet to 11 feet, and the height in front from 5 feet to 6 feet. The front sashes may be hinged half of them as you propose, or the ventilation may be in the brickwork, and the glass as well as at the rear, where two ventilators in the back wall 3 feet long, and 1 foot wide near the apex, would do for such a roof, and then all the roof might be fixed. This would, perhaps, be simpler than having three ventilators in the roof at the apex, and all the rest fixed. For such a purpose as you propose, a brick or iron stove will do, with a pan of water on it; a fire-brick on the top, would enable you to heat both houses. W. Riddell, and Lynch White's conical, without brickwork would answer your purpose, or any other small one.

DISSECTING LEAVES.—Mr. Pease has sent us some specimens of leaves "done in a quarter of an hour." They are of the Oak, and one or two other trees, and very perfect.

PRESERVING WHITE-HEADED CABBAGES (*Alpha*).—The best plan we have seen tried, was to take up the plants, or even cut them over level with the ground when the heads were quite dry, and cover them up, stems, heads, all in dry bog earth. We have also tried the same in burned charred rubbish, but not with so good effect. They will keep a good while in a cool dry shed, with their stems struck in soil; of course, the place in all cases must be dry. What say your correspondents?

VEGETABLE PLANT.—The correspondent who wished for one can be supplied by sending for it to Mrs. Potts, Gilston Road, West Brompton, Middlesex, who most obligingly offers it.

CURRENT, GOOSEBERRY, AND RASPBERRY BUSHES FAILING (*S. M.*).—Your soil being "light and dry on a subsoil of chalk," explains why these fruits fail. Your only remedy is the application of clayey loam to improve the soil; mulching over the surface to keep in the moisture, and watering liberally during dry weather in the spring and summer.

ROCKLET (*L. M.*).—You will see your inquiry treated of at length in an article by Mr. Robson next week, which we expect will meet your case, and we thank you for making the inquiry, as the subject of a rock garden had not been sufficiently treated of in our Journal.

GROWING MUSHROOMS (*A New Subscriber*).—You will see an article next week on the subject, and some others will follow. You must obtain spawn from some respectable dealer, as it is now too late to make it for use the present autumn. It is sold by the bushel, and in general is good.

WHITE TREE CARNATI & THE BRIDE (*S. Coistars, Edinburgh*).—If the plant retains its present character it will be a valuable addition to the class of Tree Carnations.

PROPAGATION OF STRAWBERRY BY FLOWER-STEM (*John Southern*).—You do not understand the case. Your specimens are merely runners bearing fruit prematurely; or the other was an instance of a flower-stalk being induced to strike root, either as a layer or a cutting. Your specimens are only instances of what occurs every year.

SIZE OF SUPPLY-PIPE.—"Whether will a two-inch pipe, or a four-inch pipe, from the boiler into three flow and return pipes, of a 4 inches diameter each, heat a conservatory in the quickest and best manner?"—K. L. M.

[The four-inch flow-pipe will convey the hot water much more quickly; and, as there are so many flow-pipes of large diameter, it would be altogether more effective than a supply-pipe only 2 inches in diameter.]

NAMES OF PLANTS (*A Subscriber*).—You is *Centaurea montana*, not *C. candidissima*. If anywhere, you may obtain *C. ragulina* by applying to some of the chief London nurserymen. Notes upon residences will continue to appear in our pages. (W.)—A form of *Leontodon hispidus*; but from the tip of the leaves cannot tell if it is any peculiar form, or merely a vigorous example of the species.

FLOWER SHOWS FOR 1861.

NOVEMBER 6th and 7th. ROYAL HORTICULTURAL SOCIETY. (Fruit and

Chrysanthemum.) Garden Square, Tottenham, G. Egles.

NOVEMBER 12th and 13th. STONE NEWINGTON CHRYSANTHEMUM SOCIETY.

Sec., W. T. Howe.

NOVEMBER 14th and 15th. CRYSTAL PALACE. (CHRYSANTHEMUM SHOW.)

Sec., W. Houghton.

N.B.—Secretaries of Societies intending to advertise in our columns will

oblige us by sending an early intimation of their exhibition days.

POULTRY, BEE, and HOUSEHOLD CHRONICLE

CALNE EXHIBITION OF DOMESTIC POULTRY.

The Meeting just closed is the first Poultry Exhibition ever yet held in Calne, and although all the arrangements indispensable to the successful carrying out of such a Show were, consequently, quite new to the Committee, great credit is due to those gentlemen for the efficient manner in which it was conducted. The entries amounted to 170 pens, a number, as will be generally admitted, quite equal to the anticipations of those who reflected on the fact, that both the Worcester and Devizes Shows are this year held within a few weeks only of the same time as that we now refer to. The pens were placed under a most commodious tent, erected by the kind permission of Mrs. Gabriel, on her land closely adjoining the lawn at the front of her

residence. We were much gratified to find that not a single instance of ill health presented itself among any of the specimens exhibited, although of late sickness has been somewhat prevalent at the generality of our poultry shows; nor can we omit to mention the wise precaution of the Calne Committee in white-washing the pens at the onset, together with posting publicly placards requesting the visitors not to handle or feed the poultry. The admission of dogs was strictly prohibited, and a good supply of gas was laid on specially for this occasion. To add to its popularity, the band of the Rifle Volunteers enlivened the proceedings by playing at intervals throughout the day, at a short distance from the poultry-tent. Calne, though small, is a very neat and healthy town, it possesses a fine old church, and in the graveyard surrounding it is to be seen a somewhat expensive tomb, erected in the year 1717, in memory of Inverto Boswell, "King of the Gipsies," who died at the advanced age of 83. The legend runs, that throughout this long life he never once slept beneath a roof, but invariably abided under the tents, at that time so universal among the tribe to which he belonged. Here we have a pretty good evidence that constant exposure produces hardihood, a hint that may possibly prove useful to those of our poultry friends, who as invariably "coddle up" their pets, and thus not unfrequently "kill them with kindness." The gipsy's tomb is a most singular and elaborate structure, somewhat injured by the hand of time, but still one of interest to the passing visitor. But to return to the poultry-tent.

Spanish fowls stood at the head of the prize list. In the class Mr. Rodbar exhibited a pen, doing his yard no inconsiderable credit, and securing to that gentleman a special prize of five guineas; an equally well-deserved slice of good luck falling to an especially good pen of White Dorkings, the property of Mrs. H. Fookes, of Blandford. Both these premiums were a liberal addition to the general prize list, being the gift of Mr. and Mrs. T. H. Allen Poynder, of Hartham Park, for the best two pens in either Spanish, Dorkings of any variety, Cochins of any colour, or Game fowls of any breed. These prizes undoubtedly added greatly to insure a keen competition. In the class for any breed of Dorkings except Greys, a mistake in entry by three different exhibitors, placed four pens of undoubtedly the best birds in the tent quite out of competition. We repeat, as we have done again and again, competitors cannot pay too much attention to the correctness of their entry papers, as any mistake here renders disqualification inevitable, nor can Judges or Committee rectify such irregularities after their admission. We fully admit the gravity of annoyance to owners from such a result; but it should be remembered that though such slips between the cup and the lip, when the fowls prove for themselves how easily they could have won, only render still more keen the disappointment. The real ground of complaint is not in the strictly carrying out the regulations, but the wrong entry beforehand. Many pens of the Bull Cochins were really excellent, still, strange to say, neither the Blacks, Whites, nor the Partridge-coloured were anything but indifferent. The Game classes were both good and closely competing. The *Hamburghs* were good compared to those usually shown in the southern counties. In Black *Polands*, Mr. T. Panton Edwards, of Lyndhurst, exhibited two pens that proved one of the chief attractions in the whole Exhibition; indeed, it is very rarely they have been equalled.

Although in the class devoted to Golden or Silver-laced *Sabright Bantams*, only three pens of the former variety were entered (not a single specimen of the Silver being shown), we cannot recall to mind so close a trial for superiority, all nine of the birds being far better than have been seen for a long time past. By referring to the prize list it will be seen that those voted Bantam breeders, Harvey Dutton Bayley, Esq., Rev. G. S. Craws, and Rev. G. F. Hodson, were the proprietors. In the class for any other Bantams, the Game were faultless, and the White-booted ones were excellent.

We do not expect to see much improvement throughout the season in either the *Turkeys* or *Geese*, which took precedence at Calne.

The Rouen *Ducks* were both numerous and good, but the Aylesbury breed were indifferently represented. The Show stood well as to Buenos Ayrean Ducks, with an entry of twelve capital pens. The first-prize pen were peculiarly small and lustrous. The plumage of many of the remaining pens was also faultless.

It is some time since we saw a show that stood so strongly in numbers, or so well in *Brahmas*, as the Calne Meeting, both the light and also the dark-fleshed varieties appear to be especial

favourites in this locality, and not a few of the chickens were unusually promising.

The "Any other variety" class was well filled, and the specimens far beyond the average of such entries. The Sebastopol Geese, a most beautiful and unique variety of ornamental water fowls, were shown in first-rate condition by Harvey Dutton Bayley, Esq. Their novelty brought many visitors. A protective price of £25 the pair prohibited sale, however. It seems somewhat singular, that though introduced some years back, and thus beautiful, they still appear to be nearly as limited in point of numbers as at the onset.

Although Calne now labours under the real disadvantage to a poultry show, of being six miles from a railway station, the birds were promptly returned; and we hear with pleasure a line is now actually in construction to the town. In future years, therefore, there is but little doubt that the Calne Show will rise considerably in importance, more particularly should the meeting take place at an earlier period of the year.

SPANISH.—First, J. R. Rodbard, Aldwick Court, Wington. Second, J. O. Brinkworth, Calne. Highly Commended, A. Heath, Calne.

DORKINGS (Grey)—First, Lady J. Cornwallis, Linton Park, Staplehurst. Second, R. Henly, Jun., Calne. Commended, R. Henly, Jun., Calne.

DORKINGS (any variety except Grey)—First, Mrs. H. Fookes, Whitechurch, Bradford (White). Second, withheld.

COCHIN-CHINA (Cinnamon and Buff)—First, Mrs. H. Fookes, Whitechurch, Bradford (Buff). Second, A. Heath, Calne (Buff).

COCHIN-CHINA (any variety except Cinnamon and Buff)—First, withheld. Second, R. Everett, Gibraltar Cottage, Monmouth (White).

GAME (Black-breasted and other Reds)—First, J. R. Rodbard, Aldwick Court, Wington (Black-breasted Red). Second, R. H. Keable, Freshwater, Monmouth (Black-breasted Red). Commended, R. Henly, Jun., Calne, V. Sandford, Chatsworth Lodge, Monmouth (Black-breasted Red). Commended, V. Sandford (Black-breasted Red).

GAME (any variety except Red)—First, A. M. Soper, Seend, Wilts (Duckwings). Second, Rev. G. S. Cruwys, Cruwys Marchard Court, Tiverton. Third, F. Baily, Calne (White).

HAMBURGS (Gold or Silver-pangled)—First, Lady J. Cornwallis, Linton Park, Staplehurst (Silver). Second, F. Baily, Calne (Cinnamon). Highly Commended, J. Gilbert, High Street, Devizes.

LACEWINGS (Silver-pencilled)—First, Miss L. Keable, Modell Farm, Lambourne (Silver). Second, E. C. Phillips, Chippenham (Golden). Commended, B. Rumbold, Calne (Silver).

POLANDS (any variety)—First and Third, T. P. Edwards, Lyndhurst, Hants (White-crested Black). Second, J. Hinton, Hinton, near Bath (Red).

BANTAMS (Gold or Silver-laced)—First, T. H. D. Baily, Ickwell House, Biggleswade. Second, Rev. G. S. Cruwys, Cruwys Marchard Court, Tiverton. Highly Commended, G. F. Hooson, North Peterbourn Bridge-way (Silver).

GIANTS (any variety except Laced)—First, T. H. D. Baily, Ickwell House, Biggleswade (Black-red Game). Second, V. Sandford, Chatsworth Lodge, Monmouth (Duckwings). Highly Commended, Rev. G. S. Cruwys, Cruwys Marchard Court, Tiverton (White); V. Sandford, (White). Commended, J. Gould Chippenham, (White).

ANY VARIETY OF FOWLS NOT UNDER THE ABOVE CLASSES—First, J. H. Craigie, Woodlands, Chigwell, Essex (Brahma Pouter). Second, J. J. Fox, Devizes (Malays). Third, A. Heath, Calne (Light Brahmas). Highly Commended, A. Heath, Calne (Light Brahmas). Commended, J. Hinton, Hinton, near Bath (Brahma Pouter).

TURKEYS—First, Miss L. Crawley, Caversham Park, Reading (Cambridge). Second, Miss J. Milward, Newton St. Loe, Bath (Black). Highly Commended, Mrs. G. H. W. Henage, Compton Bassett (Norfolk); Rev. H. G. Baily, Swinon (Cambridgeshire).

GREYS—First, Mrs. H. Fookes, Whitechurch, Bradford (Grey). Second, T. H. D. Baily, Ickwell House, Biggleswade (Sebastopol). Highly Commended, Miss L. Crawley, Caversham Park, Reading (White Dutch); H. Brown, Blackland Park (Chinese).

DUCKS (Rouge)—First and Second, Rev. H. G. Baily, Swinon. Highly Commended, Mrs. C. Sainsbury, Lower Hill, Bovingdon, Bucks. Rev. H. Keable, Laock, Wilts. Commended, J. P. Coleman, Beversbrook House, Calne.

DUCKS (Aylesbury)—First, G. Hanks, Quobwell Farm, Malmesbury. Second, G. Bryant, Jun., Littlecott Mill Wevers.

DUCKS (Black East-Indian)—First, F. W. Earle, Fidenhurst, Prescot. Second, G. S. Sainsbury, Lower Hill, Bovingdon. Highly Commended, G. S. Sainsbury. Commended, G. S. Sainsbury.

DUCKS (Any other Variety)—First, T. H. D. Baily, Biggleswade. Second, E. C. Phillips, Chippenham (Call Ducks). **SPANISH CHICKENS**—First, J. R. Rodbard, Aldwick Court, Wington. Second, J. O. Brinkworth, Calne. Commended, F. Cook, 12, Harrington Street, London, N.W.

DORKING CHICKENS—C. Smith, Durnford, Salisbury. Second, Lady J. Cornwallis, Linton Park, Staplehurst.

COCHIN-CHINA CHICKENS—First and Second, Major F. C. Hassard, Hilsca, Farnham. Commended, Mrs. H. Fookes, Whitechurch, Bradford.

GAME CHICKENS—First, W. Long, Devizes. Second, R. Elling, Sutton Priors, Warminster (Black-breasted Reds). Highly Commended, J. Keable, Tatcham, Newbury (Black-breasted Reds); R. Elling (Black-breasted Reds). Commended, W. Blenden, Calne; F. Baily, Calne (Black-breasted Reds).

CHICKENS (Any distinct breed)—First, T. P. Edwards, Lyndhurst, Hants. (White-Crested Black Polish). Second, Lady J. Cornwallis, Linton Park, Staplehurst (Silver-pencilled Hamburg). Highly Commended, T. H. Craigie, Woodlands, Chigwell, Essex (Brahma Pouter). T. P. Edwards (White-crested Polands); J. Hinton, Hinton, near Bath (Brahma Pouter); J. P. Coleman, Beversbrook House, Calne (Japanese); F. Baily, Calne (Black-spangling Long-legs). Commended, J. H. Craigie. **SWAMPYARDS FOR PINK**—First, J. R. Rodbard, Aldwick Court, Wington (Spanish). Prize, J. Lamb, Highworth (Black-

breasted Red Game). Prize, A. Heath, Calne (Light Brahma). Highly Commended, J. R. Rodbard (Duckwing Game Bantam). Commended, A. Heath (Spanish).

The Judges were Charles Ballance, Esq., of Taunton, Somerset, and Edward Hewitt, Esq., of Sparkbrook, Birmingham.

COLOUR OF POWTER'S EYES.

WILL you say in your next paper if a first-class Powter would be disqualified if the eyes do not match, one being a pearl eye and the other quite dark? Please say if that would disqualify the pen, or would an inferior bird with even eyes stand a better chance of a prize than the one named?—CHESHIRE.

[Any Powter, except white, should have gravel, orange, or pearl-coloured eyes. Imperfect eyes are a fault, but not of that magnitude as to be considered a disqualification, yet sufficient to turn the scale where the competitors are otherwise very nearly balanced.—B. P. BRENT.]

HYBRID BETWEEN THE GROUSE AND BLACK COCK.

WE have often denied the existence of crosses and, consequently, hybrids in a state of nature. We were last week compelled to own we were mistaken. We saw in Mr. Baily's shop, in Mount Street, a plain cross between the Grouse and Black Cock. We say plain because it possesses, undoubtedly, such evidence as cannot be questioned, that it is the produce of a cross.

It is, we believe, being stuffed. We will give a full account of it before long.

REMINISCENCES OF A GAMEKEEPER.

(Continued from page 80.)

A WEEK sufficed to show me I was fallen into a very land of milk and honey. My cottage was furnished not only well, but almost elegantly, and it possessed everything that could be required for comfort, ease, and utility. What a difference between the agent and manager! Instead of a written order to justify the disbursement of sixpence, I was told if I wanted anything I could have it. I was haunted by only one care; it was too good to last, and I was always on the *qui vive* to prevent or avoid anything that could jeopardise my place.

I found whenever there was the probability of a hard day, the head keeper had the gout, and his duty devolved on me; but everything was so perfect, and so liberally provided for, that even work became a luxury. Such guns; such dogs; such an unlimited number of makers, watchers, or beaters, that I often seemed to myself rather an officer in command than a servant under orders.

The manor was a beautiful one, rather hilly, but abounding in open, level spots, and offering almost any description of sport. My master was more than popular, he was beloved by every man on his estate, and for that reason the keeper's place was an easy one; every man was a keeper. I may here be pardoned if I indulge in a trifling digression. I would sooner take two-thirds of the salary of a popular man, than twice as much of one who was disliked. It was a treat to live on this estate. Capital cottages, large gardens, constant employment, and uniformly kind treatment, made a contented labouring population. Except for a fortnight before and after Christmas, and for a week or two about laying time, no real watching was necessary, and I soon found, like all the other servants, I was thriving, and my clothes were getting small. But we all saw with fear, that the life that suited us so well, was killing our master. He not only got stout but he was drowsy, and although the medical men ordered more exercise, he took less. He now rode when shooting. When I was first with him, he generally started about ten, luncheon met him at the appointed spot at two, and there was little shooting afterwards. But *they* were luncheons; not a little hand-basket of notions and remnants, but two doekys, one laden with paniers, the other with a keg and bottles.

The house was always full of company in the shooting season, and two or three parties, of two each, in September, had their beats and keepers appointed to them, with instructions to meet at luncheon-time. No office was so serious in my master's eyes as to be unpunctual. The steward's-room boy and a stout lad accompanied the luncheon, and with our help it was soon

spread out. Those paniers were rich ones; every description of pie, cold fowls, small hams, large tongues, sandwiches, fruit, &c., all packed in metal cases that fitted in a box which formed the table. Silver forks, spoons, and goblets, and in winter I have known hot soups and made dishes sent out into the covert. All sorts of wine and mineral waters loaded the other donkey, while the keg was filled with beer for us. Luncheon always lasted an hour, often more. Nothing eatable was returned to the house, but all was given to the keepers and others. It was the head keeper's place to name the spot, and he generally pitched on a summer-house or good shed, except in very hot weather, when he would select some shady, sheltered spot, where timber sticks were lying.

In the early part of my stay there, luncheon was generally over, and the cigars finished by four, and one hour's shooting brought us to the Hall. Master was too fond of eating and drinking, but there was nothing selfish about him; he wished every one to be like him, and has told me hundreds of times jokingly, that if I did not get fatter he would discharge me. Now, master rode his pony, many days he scarcely shot at all, and on others he would ride straight to the luncheon spot, where we should find him asleep on our arrival. He was listless and careless about everything except his eating and drinking, and it was only after luncheon he rallied and became somewhat like what he used to be. He would eat, drink, and smoke till he fell asleep, and would forbid us to awaken him until the carriage had ordered came for him.

PARTHENOGENESIS IN THE HONEY BEE.

I ENCLOSE a full report by the operating surgeon of the post mortem examinations of a perfectly fertile queen, a couple of drones, and a drone-breeding queen, which took place at the Devon and Exeter Hospital, and which will be found much more full and complete than the account already given by "A DEVONSHIRE BEE-KEEPER."

"EXAMINATION OF THE SPERMATHECA OF A PERFECTLY FERTILE QUEEN (September 28).—The sac was about the size of a mustard seed—spherical, opaque, milk white. A canal passed from it into the oviduct. On rupturing it on a glass slide, a milky fluid flowed out, which immediately covered with a piece of thin glass, and examined under the microscope with a power magnifying 220 times, showed countless numbers of minute, attenuated filaments, rapidly moving in ceaseless gyrations, but forming such a dense mass that it was impossible to trace any one thread separately. Pressure was applied, and some of the fluid squeezed out from between the glasses, leaving behind a very thin stratum. Each filament could now be separately traced, and appeared as a transparent structureless line, without any dilatation throughout its length, indeed both ends became so greatly attenuated that they were scarcely visible. These points were made out more clearly by applying higher powers, magnifying about 400 and 700 times. The movements adopted by the spermatozoa were chiefly in circles and figures of 8, but this doubtless was partly due to the pressure used and the narrow limits allowed them, as in subsequent examinations some assumed a more longitudinal direction. A diagram of a spermatozoon of an insect, and pretty accurately corresponding with those just described, is given in Griffith and Henfrey's "Micrographic Dictionary." The ovaries were examined but appeared to be quite empty (it was the end of the season), no ova nor germ masses in any stage of development could be made out, a little diffused granular matter seem'd all the only contents."

"EXAMINATION OF THE DRONES (October 7).—The testes, seminal receptacles, and auxiliary organs of a drone having been carefully isolated, and their connection with the muscular ejaculatory sac by means of the excretory duct, traced—the yellowish, somewhat fusiform seminal receptacles were successively opened, and the contents of each examined with 1-5 and 1-8 inch lenses. The fluid, besides granular matter and (apparently) nuclei, contained abundance of linear, rapidly moving bodies, exactly corresponding with those found in the spermatheca of the queen previously examined."

"The opaque, glistening, pearly white, cylindrical coeca, larger than the seminal receptacles, and into which each of these latter opened respectively, were found to contain a granular, very viscid fluid in which, after a very careful search, no spermatozoon whatever could be discovered. The posterior extremities of the two coeca almost or quite coalesced, and from the point of union the common excretory duct took its origin."

"EXAMINATION OF DRONE-BREEDING QUEEN (October 13).—The spermatheca when isolated was rather smaller than that of the perfectly fertile queen, and, unlike it, was colourless and hyaline. The wall of the sac, though transparent in most of its extent, had several semi-opaque spots on it, which subsequent examination proved to be adhering connective tissue, tracheae, &c. On pricking it with a fine needle, a clear, extremely limpid fluid exuded, which, examined as before, was found to contain neither filaments, cells, nor nuclei, a very few scattered granules were alone visible in it. Further careful examination of the remaining contents of the sac equally failed in detecting a single spermatozoon."

"The microscopes used in these investigations were those of Messrs. Powell and Leland, and Smith and Beck.—J. U. HUXLEY, October 20, 1861."

AN OBSERVER PUZZLED.

WHILEST beguiling a leisure hour by perusing the apian articles contained in the last two volumes of THE JOURNAL OF HORTICULTURE AND COTTAGE GARDENER, I was rather surprised to find that your able contributor, "A KENFREWSHIRE BEE-KEEPER," avows himself in No. 661, old series, as being the same correspondent who writes also under the signature of "A YOUNG BEE-KEEPER." Remarking at the same time, that under the first appellation he boasts "a still longer experience" than ten years; whilst in the latter character he modestly hints at his "limited experience." I should be glad to be informed, if his really excellent contributions are to be ascribed to the wonderful precocity of a comparative novice in bee-keeping, or are to be valued as the results of a lengthened experience.—OBSERVER.

FECUNDATION OF THE QUEEN BEE—RAPID MULTIPLICATION OF LIGURIAN STOCKS.

I REGRET that I am unable to furnish "INVESTIGATOR" with precise information respecting the age of the young queen with undeveloped wings, at the time she was removed. My impression is that she was three weeks old, and the distended state of her abdomen satisfied me that she was about to commence egg-laying. The malformation of her wings being evidently congenital, I was rather surprised that it had not earlier attracted my attention; but, happening to have queen cells in a state of forwardness at the time, and the season being so far advanced, I destroyed her at once, and substituted a couple of royal cells as the only chance of furnishing the stock with a fertile Ligurian sovereign. I should add that there were no drones in the hive.

I find that I mistook "INVESTIGATOR'S" query regarding a second "foundation," owing to his using the word in a different sense to that in which I am accustomed to apply it. I have for some time suspected that more than one copulation may occasionally take place, although I have not been so fortunate as he appears to have been in verifying my suspicions. If I were inclined to theorise on the point, I should conjecture that the sexual impulse on the part of a queen bee is not altogether allayed until her spermatheca is completely filled with male semen, and that as the size of that organ varies in different individuals, some may require the services of more than one drone to effect that object, and such would very probably turn out to be possessed of an extraordinary degree of fertility. When either an impregnated or virgin queen commences egg-laying, I believe all sexual desire on the part of the female is extinguished for ever.

The ten colonies raised from one stock were formed in this manner—during the months of April and May eight small artificial swarms were taken out on the following days:—17th, 24th, 26th, and 29th of April, and 9th, 16th, 23rd, and 25th of May. At this time honey was collected in such enormous quantities that the queen could not find an empty cell, in which to lay an egg. Seeing, therefore, that breeding was nearly put a stop to, I was compelled to give room, which I did, by putting on a super 13 inches square by 7 inches deep: this was filled, and when taken off contained 38 lbs. of excellent honey.* The bees were afterwards employed in finishing a super taken from another hive; but the honey season being over, they did not make much progress, and on the 9th of August a very large artificial swarm, being the ninth and last for this season, was formed.

* This super may be seen at Messrs. Neighbour & Sons, 149, Regent Street.

Of the first eight swarms several have been dispatched to different parts of the kingdom. During this present writing I have had a visit from a friend residing near Honiton, who possesses one of them. He tells me that he has placed it in a hive, 18 inches by 14½ inches, and 9 inches deep inside, with twelve frames, which it has completely filled; and he declares his firm belief that it is more populous than any stock of common bees in the kingdom. The others, after divers revolutions, which have resulted in their sovereigns founding new dynasties in distant regions, or perishing in the attempt, have been recruited by the addition of common bees and a copious supply of food, and now appear sufficiently strong to stand the winter.—A DEVONSHIRE BEE-KEEPER.

YOUNG BEES EXPELLED FROM HIVES.

To assist "A PERPLEXED YOUNG BEE-KEEPER" in elucidating his difficulty as to his "Young Bees Expelled from Hives," I may mention that such a proceeding is by no means rare;—indeed, we have had considerable experience of it in our locality, and can confidently attribute it solely to an erroneous estimate of the ways and means.

It generally takes place, should congenial weather set in, towards the end of the season, with a large quantity of brood verging towards completion; and where it is carried to an alarming extent, we have invariably found it in hives possessing young queens, although it sometimes occurs with a very late swarm.

We have often compared expelled young bees with those emerging upon driving a hive, and found wings and every other portion as fully developed in the one case as in the other, but only weaker.

Should a hive in this condition be transported to a later locality or the moors, and honey gathering set in, I will warrant it will be completely checked. Or even if feeding be continuously persevered in it will have a similar effect, in exemplification of which take the following case.

A friend had a Stewarton-hive a few years ago which changed its queen in the month of July. After the old one had been put out, he saw the youthful successor to the throne take two or three aerial excursions. As nearly as he can recollect it weighed 50 lbs. in three boxes. The hive began to expel bees to an alarming extent. About the middle of August he converted 4 lbs. of sugar into syrup, gave half one evening, the other the following. This partially checked the evil; but in two or three days it was renewed as determinedly as ever. Fed as before two days, after which gave 1 lb. daily for the succeeding five or six days. This had the desired effect, and he had the pleasure of witnessing plenty of young bees taking wing afterwards. The hive did well the following season.—AN AYRESHIRE BEE-KEEPER.

UNITING BEES.

ALTHOUGH unwilling to differ from so good an apiarian as "A RENFREWSHIRE BEE-KEEPER," I am of opinion that the reply which was given to "A. W.'s" inquiry was perfectly correct. I have invariably found that a queenless hive placed upon another possessing a queen is (after fighting is over), treated as a super, and that the lower one becomes the stock-hive.—A DEVONSHIRE BEE-KEEPER.

"B. & W.'s" APIARY IN 1861.

(Continued from page 509.)

It was on the 18th of July that I made the transfer of stock boxes D and A, depriving the latter of its queen, and compelling the bees to rear an Italian hybrid out of the brood of D. My first intention had been to make of this stock a sort of nucleus for the rearing of a sufficient number of young queens to supply all my other stocks. As it appeared, however, that they had only one properly-matured royal cell on the 25th, I did not venture to disturb them again. Nothing remained but to repeat the operation of the 18th, which accordingly I did on the 2nd of August. Driving the Italian queen a second time out of her box, a quantity of brood ceased and unceded, and eggs too were found in it; all the latter (unceded brood and eggs), I assumed to be pure Italian brood, as a fortnight had elapsed since the first transfer. A piece of this brood in the comb was given to E, in the hope that the bees here would behave better than they did on the 25th of July (as related page 509); but again they

refused to rear a queen, merely contenting themselves with laying the foundations of a royal cell, in a bit of empty comb abutting on the piece of Italian brood-comb which they wholly neglected. At first I thought they might have done this for convenience, intending to transpire one of the eggs; but, although evidently aware of their being queenless, they persisted in ignoring their duties, and the royal cell remained unoccupied.

To return to the Italian stock. Having taken out this piece of comb and given it to E, I put the box with its remaining contents of Italian brood in the place of C, the strong artificial swarm of May 24. C itself, queen and all, was shifted to a new stand in my garden, excepting a super full of bees, which was placed over the Italian box in the bee-house. In a few days the great majority of the bees of C found their way back to their old locality, and everything went on so favourably that on the 5th six royal cells were found tenanted, one of which with a whole comb of brood I put into a small box and gave to E, resolved to give them one more chance. On the 13th, I took out another comb containing four royal cells ceiled over (leaving two behind), and gave them to F. This stock I intended to treat in the same way as A and C; but on driving the bees out I found a quantity of artificially-formed royal cells in every stage of progress. No doubt the old queen had lately come to the close of her natural life, and the bees were repairing their loss. Every one of these royal cells I carefully cut out, and substituted a bar of Italian brood with the royal cells taken from G. Thus it will be seen C became a nucleus, which supplied E and F, as well as itself, with Anglo-Italian hybrids. Each of these three stocks has since done remarkably well. C and E especially have very fertile queens, which have been breeding rapidly the last three weeks, during which time I have been feeding largely with the bottle throughout my apiary. F has only just begun to carry pollen, but I doubt not they have a fertile queen. The queen of E I set eyes on on the 20th of August. She being herself a pure-bred Italian, was beautifully marked: her offspring, of course, will be hybrids. This stock was so very weak in bees at the beginning of September, that I hardly expected to save it. However, by adding bees and brood taken out of other hives, the population so far increased as to suffice for the wants of the young hybrid brood, and it is now rapidly increasing in strength. In fact, I look upon it as the most promising stock in my apiary, judging from the extraordinary quantity of pollen (extraordinary for the season and the circumstances of the hive), which is daily being carried in. C, however, is by no means inferior in promise.

Thus it will be seen four of my English stocks had become successfully Anglo-Italianised. B only remained to be operated upon. This was supplied on the 16th of August with Italian brood direct from the parent stock D; by repeating the process of transposing the boxes, D and B (as in the case of D and A and D and C) after killing the young English queen of B. Both B and D were full of brood, so that neither have suffered by the transposition in regard to population. Everything went well here, as in the case of the other hives. The young queen was hatched in due time, and has just commenced laying, pollen being carried into the hive in large quantities. The pure Italian stock has gone to rest for the present, while all my five Anglo-Italian hybrids are in full vigour of breeding. This is to be accounted for by my having taken to feed them liberally to make up for the great consumption of honey which has followed upon these various operations.

It only remains for me to re-arrange the order of my apiary as it now stands finally disposed for the winter. In the bee-house my six stocks are as follows:—

A. (Anglo-Italian hybrid queen, artificial. July, 1861.)	B. (Anglo-Italian hybrid queen, artificial. Aug., 1861.)	C. (Anglo-Italian hybrid queen, artificial. Aug., 1861.)
D. (Pure Italian queen, artificial. June, 1861.)	E. (Anglo-Italian hybrid queen, artificial. Aug., 1861.)	F. (Anglo-Italian hybrid queen, artificial. Aug., 1861.)

With these six stocks I propose to work my apiary, if all is well, in 1862. G and H having English queens, are to be removed to a bee-house belonging to a clerical neighbour four miles off.

Before I close, I wish to speak a word in favour of the bottle-feeder recommended by "A DEVONSHIRE BEE-KEEPER." I have two of Messrs. Neighbour & Sons' feeders in operation, but any common wine-bottle will do equally well. This is decidedly the best mode of administering food to bees which has

come under my observation, nor I believe can it be excelled. It is the *ne plus ultra* of bee-feeding.

I may further state that my honey harvest has reached the amount of 207 lbs. weight of honey and honeycomb, of which I have sold upwards of 1 cwt. for £7 0s. 2d. Some of it fetching as high a price as 1s. 6d. per lb. This is decidedly the best honey harvest I have ever had from only seven hives partially plundered.—B. & W.

A PLEA FOR A FEW MORE SMALL FARMS.

In your No. 613, Mr. Appleby gives some hints to gardeners, and as there appears to be a greater supply than there is a demand, Mr. Appleby offers several suggestions as remedies. Firstly, not to train so many young men to the profession; secondly, emigration; and thirdly, to turn their attention to farming.

On the two first remedies I shall have but little to say; but if there are fewer young men trained to gardening, there will be less need of emigration, except from choice. But for a man to turn farmer is much easier said than done; and to become a first-class farm labourer (which he could not) would not better his condition at all; and if he was competent to become a farm bailiff, or manager, he would find but very little elbow room there, as there are scores of farmers' sons, either from want of capital to stock a farm, or from the want of a farm to employ their capital upon, that would be glad to take situations of that description for very little pay, merely to get a start from home and in the world, and would be taken in preference to a man having a knowledge of gardening only. And to become a farmer to live and thrive by farming requires, besides a knowledge of cultivating land, a knowledge of buying, rearing, and managing stock on first principles, though on a small scale.

This is the additional knowledge that is required by young gardeners to make them the most useful, the most sought after, and the best paid men in the country, and what is more difficult to obtain than either the knowledge or the means to farm with, is the farm.

There are hundreds of careful, industrious, practical men at the present day, whose family has increased beyond the limits of a gardener's cottage, that would be glad to rent from five to twenty acres of land, would give more rent for it than the large farmer, produce double the crop, be a valuable member of society, keep down poor rates, and bring up his family to a knowledge of industry and independence. Although the above is very desirable, at present it is not comestable to the extent required; still there is another door open for the young gardener who cannot see a prospect of realising the hoped-for position as a gardener.

It is pretty well known that the merchant and manufacturing gentry of the higher class take every opportunity of enjoying a country residence; and whether they buy a property or rent one, a good deal of alteration generally takes place; labour is employed, and money is circulated, and the neighbourhood is generally much improved, and the gentleman is in hopes of enjoying the bounties of nature raised upon his own land. The vegetables fresh from the earth the morning they are dressed; Strawberries on the breakfast table with the morning dew upon them; the cream genuine, thick as custard, just brought from his dairy; eggs warm from the nest of his own fowls; and then what butter! and the guest declares he never ate such butter before; and the lady of the house very seriously informs him that they consume double the quantity of butter since they have had a dairy, and she must have another cow to supply the house with butter all the year round, as she must have the cream, and cannot eat bought butter. This is not imagination, but what really took place. And what beautiful fowls too, plump and tender. A certain city friend on each visit always stipulates for fowls and bacon for dinner. And don't the gentlemen at the dinner party find a subject for conversation in that quarter of lamb! "My own rearing, gentlemen, and fatted on my own premises. My first attempt; hope to do better next year." But every one exclaims, "splendid!" and in drawing the carving-knife through the kidney he experiences a pleasure much better felt than described. But this is only a part of the enjoyments. Who can enjoy that cream and butter without having a desire to know something of its manufacture? and every fresh visitor must see the cows milked, and the butter churned, washed, and made into breakfast pats. Then there is the poultry. Of course they must see the poultry fed, and away goes Peter with the food to the fowls. Barton, the lady and gentleman of the house, and the visitors following closely to see the force of

habit, which the master of the house has just been discoursing about. The food is strewn about a nice gravelled yard, with pens for various purposes round the north and west walls. But where are the fowls? A glance from master to man tells at once who enjoys the fun. Then Peter gives a whistle, both loud and shrill, and down comes a flock of Pigeons; then rushing helter-skelter over the wall and through the doorway whole troops of fowls of all sizes; and last of all come waddling through the grass, heads erect, forty-three Aylesbury Ducks. I have seen them when returning home at night, all in one line—a sight worth seeing.

"I should think it must take a long time to learn them your whistle, Peter?" "Well, no sir, not very long, though perhaps I may whistle a very long time for any other purpose before they would understand me." "But what is become of the chickens?" Then the master points out the above-mentioned pens, and explains his success in rearing poultry. These pens are chiefly made of laths partitioned off into four compartments. No. 1 has a very small entrance for the youngest; No. 2 a little larger, and so on to the fourth. There is food and water kept in each pen, so that the chickens can go to it whenever they like. There are holes in the partition, so that if No. 1 should by mistake run into No. 4, they pop into No. 3, and so on till they get into the right one; but they rarely make a mistake.

I must leave the sheep and lambs till a future day, and come more to the point. The gentleman and his family are enjoying the fruits and pleasures of rural life; and there is not a village in the country but contains one or more such property, to say nothing of the number in the vicinity of towns, and yet they are only enjoyed in part. There is the garden with its fruits and its flowers, but where is the land? Why, the nearest farmer rents it, and if the gentleman is asked why he does not keep it in his own hands, he tells you he cannot get a man that understands the management of these things and the garden. Another will say, "Well, I have tried it, and there is always something going wrong, and in the end I am considerably out of pocket by it."

Now, here is a field open for the surplus gardeners. Gentlemen would be only too glad to meet with such men as Peter, and give them better wages than nine out of ten would ever get as gardeners only. They have only to wish it and it is done; but the "how and the why" shall be given in other papers if not objected to.—THE DOCTOR'S BOX.

THE KERRY BREED OF COWS.

CROSSING the ch-mud, we find that although the cattle met in different parts of Ireland present a great diversity of type, the unimproved cattle of one district differing materially from those in another, there is one distinct native breed, possessing certain characteristics, which renders the neglect with which it has been for the most part treated the more disgraceful. In fact, it would almost appear as if breeders of Keries had entered into a combination to destroy it; but despite of all the neglect the breed has experienced, still pure-bred specimens are to be found of such uniform character that it is evident it only requires a man possessing sufficient skill and judgment to set about breeding Keries in a proper manner to render it one of the most valuable "fancy" breeds of cattle in the kingdom. As it is, they are eagerly sought after; but there are plenty of cattle sold as Keries which are not pure bred; they may have been bred in Kerry, but they are not Keries.

True-bred Keries yield rich milk, and that, too, in much larger quantities than one would imagine from their diminutive size. When put on good keep they fatten readily, and their beef is fine in the grain, and of an excellent flavour. In the latter point the Keries and Z-land cattle are superior to all other breeds, closely resembling each other in the quality of their flesh.

The pure Kerry is small, light, and active; the head is small and fine, with a clear, bright eye; neck fine; horns short, and turned upwards. Sometimes the horns are not "cocked" alike, there being a kind of twist in the "cock," and some look upon this as one sure mark of a true Kerry. In general, they are light in the hind quarters, but high-boned, and wide over the hips. The colour is varied, being either black, red, or brindled, or piebald in any of these colours. When kept on their native mountains their hair is long and rather coarse, but it becomes short and fine when they are brought to better keep. If means were taken to improve the breed it would be advisable to secure, if possible, a distinguishing colour; and, probably, a piebald

black and white would be the best, particularly as such marking would be more liked in a fancy animal than, for instance, a pure black. This, however, is a matter of taste, but uniformity would certainly be highly desirable.

We have said that the breed is small; and as an example we may remind our readers that a beautifully finished Kerry cow was exhibited at the winter fat stock show of the Royal Dublin Society in 1860, which was only 38 inches in height at the shoulder; 70 inches in girth; and 42 inches in length from the top of the shoulder to the tail head; indicating a weight of about thirty imperial stones.

Some have proposed improving the Kerry by crossing with some kindred breed—the Snye Highlander, for instance; but we would most strongly condemn such a proceeding. We believe that the improvement of the Kerry, and the establishment of a uniform character, both in shape and colour, must be effected by judicious and skilful selection, and by that alone. There is ample material for doing so, and we feel assured that any sensible man, competent for the undertaking, who will go quietly and judiciously to work in this matter, selecting the best and purest-bred sires and dams to begin with, of a uniform colour, &c., if possible, and carefully culling any of the produce which does not come up to the mark, will be amply repaid for all his trouble. This should be done, however, in a high-lying district; for the cultivation of the breed in this manner, where the pasture is rich and the climate genial, might lead to its complete alteration, at least in several of its characteristics.

When put to short-horn bulls, Kerry cows produce good crosses, much larger than their dams, which fatten readily, and produce good beef; but in the meantime we would much rather see the improvement of the pure breed earnestly and judiciously carried into effect. The Bretonne cattle resemble the Kerry very much in their size and general appearance, as well as their milking qualities, and it is evident that the two breeds are closely allied. Indeed, from the proximity of Brittany to Kerry, it is not at all unlikely but that there have been, at some remote period, a transmission of cattle from the one place to the other.

We have alluded to the diversity of appearance which is to be seen in the cattle found in several parts of Ireland. This has arisen, in a great measure, from the numerous breeds which have been introduced, especially bulls, from time to time, and the careless and irregular manner in which these have been used by the common class of farmers. The imported bulls might be used for a season or two, and the produce would then be put, perhaps, to a cross-bred bull, or a bull of no particular breed, simply because such a bull could be got for a shilling, or because the cross-bred bull was most convenient. From this cause, among others, there is, in many parts of the country, a race of mounds, which it is impossible to assign to any particular breed, whilst in others we may readily detect traces of some distinct breed. Thus, we find in the north that polled animals are by no means scarce, showing that the use of Galloway bulls, which was much in fashion in that part of Ireland at one period, has left its marks, although the polled specimens we now meet with are of all colours except that which characterises the Galloway. In other cases we find evident signs of a crossing, more or less remote with the Ayrshire, the Hereford, the Devon, the Dutch, &c., so that in some country fairs we have seen descendants of half a dozen of different breeds, and not a pure-bred animal of any breed on the ground. Matters, however, are improving in this respect, at least where landlords have the good sense to keep up a constant succession of pure short-horn bulls for the use of their tenants; and we could name districts where the most marked improvement in the description of cattle found in the hands of the ordinary run of farmers has taken place, solely in consequence of the landed proprietors in those districts having adopted this most judicious course. We must protest, however, against the use of cross-bred bulls, a practice which is, unfortunately, too common; and we are sorry to see that it is even encouraged by some farming societies giving prizes to such animals.—(*Irish Farmer's Gazette*)

INSECT VAMPIRES.

In a little practice like mine, within a month I have had ten cases of rather severe erythematous inflammation, apparently from stings or bites of plants or insects.

But one out of the ten suffers much from the bite or stings of gnats, bees, or wasps, and the majority have never been bitten by flea or bug.

There is a small central puncture in every case, and they are all situated on arms, legs, and neck: exposed parts. Has any other practitioner observed this kind of attack?

Has the great heat hatched any new noxious insect? or are our gnats undergoing "progressive development" into mosquitos, or into that dire African insect mentioned by Livingstone as an unpronounceable name, having e and z in it?—*RUYER, Isle of Elg.*

RHUBARB AND MULBERRY WINES.

The following are two very good receipts:—

RHUBARB WINE.

Cut rhubarb as for tarts, and to every 4 lbs. add 1 gallon of boiling water. Let it stand twenty-four hours, then boil it with 3 lbs. of loaf sugar to each gallon, for half an hour; work it with yeast on toast, and afterwards put it in a cask with 1 oz. of isinglass, and 1 pint of brandy.

MULBERRY WINE.

Gather the fruit dry, squeeze and strain them to 1 pint of juice; add 1 pint of water, and 1 lb. of sugar; set it to work with a crust of bread and yeast. Afterwards put it in a cask, in which it must stand six months. When you bottle it off add a little brandy to each bottle.

OUR LETTER BOX.

EAR-LOBES OF DORKING COCKER (E. S.).—The semi-white ear-lobe is quite as correct as a red one. If he is intended to be shown with pullets or hens in class, his speckled breast would disqualify him for any other than open competition. He will, therefore, be shown as a "Dorking." The breast of a "Silver Grey" must be black.

GAME FOWLS SNEAKING (Chester).—The wet and cold weather have had an influence on your fowls. They have caught cold. Give them, directly, stale bread, steeped in strong ale, three times per day till they have recovered from their sneezing. Discontinue the Indian corn, it is bad food for poultry. Give potatoes sparingly, bread freely, and ground oats once or twice per day, and give some peas daily for a week or fortnight before exhibition.

ACCOMMODATION FOR FOWLS (Bob).—You may keep Spanish, Cochins, or Bracons, in the space you name. The accommodation place must not be airtight; it wants ventilation all round, but above the perches. If the woodwork is painted, no fowls must be put in till the paint is really hard. If the wire is 6 feet high, there needs no covering at top, as the birds will not fly over.

EGG PROTECTOR POTLRY (H. F.).—Having a supply of eggs solely in the hands of the Darker-fathered Cocker-Chester, and pulling off the Silver-penciled Hamburgs are to be selected. The Cuckoo-Chinas will lay through the winter, and when they become broody in spring, the Hamburgs will continue the supply and never want to sit.

GAME COCK'S HOLE BROKEN OFF (An Amateur).—We do not consider the loss of a heel important to a game cock for exhibition. Those accidents only are important, which may be considered, without illiberality, to remove or conceal a defect.

AGE OF PENCILED HAMBURG CHICKENS (Fair Play).—We did not see the fowls in question, and cannot, therefore, give either an opinion or information on the subject. Mistakes are often made unintentionally, and in this case, the class being for Chickens of 1861, the birds would be eligible, even if they were three months older. As a proof that mistakes are made, one of our most experienced exhibitors showed a pen of chickens in a chicken class, in October, and described them as eleven months old, hatched early in January.

STEWARTON HIVE (W. Johnson).—The reply you refer to is a printer's error. It should have been No. 16 of our New Series. If you send us the Number you have purchased we will send you No. 16 in exchange. If you also send us 500 of our first Series, you will see in that a drawing of the hive improved.

LIGURIAN QUEENS (A Subscriber).—I regret to state that after devoting two seasons to the attempt, I have failed in raising a sufficient number of Ligurian queens to supply those who have applied to me. An endeavour to obtain a few more, by the same method, has been unsuccessful. With reference to the annoyance is, the number of failures which have taken place in substituting Ligurian for native queens, although I gave the best instructions in my power for performing this operation in THE JOURNAL OF HORTICULTURE, in the 25th May last. My present intention is, for the future, to turn my attention to multiplying stock, which will travel safely to any distance, and are free from the uncertainty attending the introduction of queens. An advantage will be offered to them who are on my list of subscribers for queens. Taylor's "Bee-keeper's Manual" contains good instructions for bee management, but I should advise "A Subscriber" to enquire collateral and nether-lying.—**A DEVONSHIRE BEE KEPT.**

WORK ON CIDER (Apples).—We have seen no private work on the subject since the late Mr Knight's "Treatise on the Culture of the Apple and Pear, and on the Manufacture of Cider and Perry." The last edition, we believe, was published in 1858. The last novel essay we have read is Crocker's "Art of Making and Managing Cider;" but we have never seen the volume. There is a good treatise on the subject in the "Penny Cyclopædia; and another in the "Library of Useful Knowledge"—British Cyclopædia," vol. II., and a third in Baster's "Agricultural Library."

BRUZZEL (W. C.).—Redpolls are rarely little birds and easily kept; feed on canary seed. An occasional tincture of maceweed may be allowed, but it is better to avoid hemp seed, such being too gross for birds in confinement (it would be like keeping a clerk close at huskies all his life and feeding him on fat pork). They few get larval to it, the majority become diseased sooner or later. Clean water, sharp sand, and a good supply of green food, such as chickweed, groundsel, shepherds' purse, plantain, dandelion heads, &c., will be the best addition to the universal canary seed. The red on the head does not wholly disappear in confinement, but changes to an orange shade, the rusty breast of the adult cock also changes to a buff.—**B. P. FINN.**

WEEKLY CALENDAR.

NOV. 5-11, 1861.			WEATHER NEAR LONDON IN 1860.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 51.9° and 35.8° respectively. The greatest heat, 63°, occurred on the 5th in 1852; and the lowest cold, 18°, on the 9th in 1854. During the period 122 days were fine, and on 116 rain fell.

PHASEOLUS CARACALLA—VENTILATING AND PRESERVING ICE.

HERE is a printer's error in the second name of the queer-looking flower which "D." of Deal, mentioned last week, and which he thinks might make a good greenhouse climber. From his description of it, "the buds are exactly like a ram's horn, twisted in the most curious manner," an old shepherd converted to the ancient craft of the practical gardener can readily perceive the climber is Phaseolus caracalla, and if it would submit to in-door cultivation it would, indeed, be a striking climber in a greenhouse, but it refused to do anything of the kind in my younger days. There is no plant allied to Desmodium, to Hedysarum, or to Swainsonia, in the Indian jungles,

which is more impatient of in-door work, or more liable to the attacks of the red spider, than the "Hooded Runner"—the old name we had for Phaseolus caracalla. It is a case exactly opposite to that of Bougainvillea spectabilis. Old gardeners, myself amongst the rest, knew as well as we did our pruning-knives that no mortal could bloom that plant in England to pay for its keep, while at Paris we knew it was bloomed yearly to perfection: and the cry about it, as having been conquered at last in England, was not made by men of practical knowledge, but by others who were on the wrong scent all the while—Bougainvillea speciosa having been mistaken for spectabilis. But there is no mistake about the ram's-horn flower, in bunches like those of a Glycine.

Phaseolus caracalla would flower as freely in England in a greenhouse as a Scarlet Runner would at a cottage door, if you could grow it, and it grows as freely as Dolichos lignosus, the freest of all the old greenhouse climbers, out in the open air in most parts of England, but will not bloom outside and inside a house. It is the most difficult plant in cultivation to do up to moderate. It is only right, then, to give the warning in time.

I am firmly of the opinion that our credit here in England for fair play, fair criticism, and fair, honest counsel in our gardening pursuits, has been in the balance for a considerable time last past, and is beginning to tell unfavourably on us gardeners, as a class, because it is found wanting. I could go back ten or twelve years and prove from black and white, that that which is white on one side is not white on the other side, that things have been said and done when we did not expect, when we wanted rather to improve our credit, as just and fair writers on and about our things, immediately previous to 1840, when our credit was lost in the balance for blights.

Take one example of what I allude to, and then decide. What would they say of one who announced only a week or two back that the ventilating of ice-houses was a new invention over from America, not from Paris this time, while there is hardly one whole volume of this Journal from the second year of its age, which does not recommend that process as the very best and safest way to keep ice? And in one of the early volumes it was told and explained that an M.P., who may now be said *as then* for some part of Cheshire, had instructed THE COTTAGE GARDENER to keep ice where he never could keep it before, that THE COTTAGE GARDENER did as the M.P. said, and found it to be the real secret for keeping ice, and that the "invention" was due to a London architect. Now, all these people, and all our own readers, know all that very well, and they, or none of them, would now fight for or against the Americans for a new invention which we ourselves sent over to America twelve years back.

Now, this ice "invention" will be a very serious business this winter. Suppose the ice will be a foot thick, how do you mean to keep it—Wenham Lake fashion, or how? But suppose the ice shall not be thicker in the winter of 1861-62 than the old sixpenny pieces were which were called in with the rest of the sillar in 1816?

How will such ice, or how can such ice, escape deluge and destruction if it is sent up in old ice-houses, with so many doors in the passage to the ice-well, and so much straw stuffed between every pair of doors? It would be all up with it ere the dog days were in.

But suppose the ice shall be just at the skating-point of firmness, how will you proceed? Will you try this American invention of ventilation, or will you chance it, and put up fifty loads of it for every fifteen you may want and for every five which will be used? The more ice the more labour in cold weather, and the more labour the more hearts will be warmed—not by the ice, of course, but with the toast and hot ale which should come in at the pounding, and pummelling, and stamping-points of the process.

The first thing to be done about ice is to see, before Lord Mayor's day, that the ice-house is or has been perfectly swept and cleaned out, and is then as dry as a neatly Potato, and if it is not so dry and smells just as sweet, that will be the first error. Then see to it at once. The second step about ice, in country places, is to be taken when all the autumn leaves are down. You are to see that the pools, or ponds, or lakes from which the crust is to be procured are not choked with the fallen leaves, or those of Water Lilies, or with Rusli-like growths, and also that no sewage-like runnings have found their way to where the ice is to be had. And the third step involves two more steps, the third itself being to begin collecting ice in such a winter as this is to be, when it is as thick as a half-crown piece, for it keeps all the better by the "American invention"—at least it used to do so with me fifteen years back, when it could be had no thicker than two half-crown pieces put together. The two steps which are involved in the third are, the one to see that all the hooks for pulling the broad sheets

ashore are in the right place to find them on the morning of the first snow, are in right sockets to stand out the work without repairs, and that the handles are sound and safe, and may be trusted with the weight of a man if properly handled on the centre of gravity. I have seen a man go down, front foremost, his whole length through a sheet of ice he was hauling with a rotten pole and a hook at the end of it, and his end was not far off if friends had not been near.

The other step is about the boats, carts, stages, sledges, as in running the ice down a bank, and who are to be pikemen and who the smashers, and who will pound and pack in the well the first part of the first day. Now, unless any one of these steps is taken in the right direction, the first half of the very best day of the ice season is lost, say for twenty men and eight horses—a very moderate allowance for an ordinary family with an old-fashioned ice-house. In all the old-fashioned ice-houses there is a passage from the outside to the well of ice, and through that passage the ice after being pounded outside has to be carried to the "well," and thrown in through a door in the vaulted roof. That is or was the worst arrangement of the old school. The best of such ice-houses had a man-hole on the crown or very top of the dome over the ice-well, and through that hole the ice was thrown at once from under the clubs of the pounders down into the very centre of the well. When all was finished, that top opening and all the doors and passages were stuffed with straw to keep the ice from the air, and there is where the great error rested. The moment the first particle of ice melted a vapour was formed, and the vapour being warmer than the ice, and being confined all round it, was the cause of the ice melting four times faster than it would, if it had not been in contact with the warm, moistened air.

The "American invention" is not so practically good in detail as the account of it which we sent there in 1849, as you may see by reading the first essays in the second or third volume of THE COTTAGE GARDENER, and by comparing them with the last accounts from America. When an ice-house of this description is properly ventilated, the best plan is not to put straw between the ice and the sides of the well, or house, for this reason—the ice begins to melt first next the straw, and the straw never gets dry afterwards; and after it is once wetted it helps to melt the ice, because the air cannot get at it *in a current* to dry it, or to carry the damp from it; whereas, without the straw round the sides a cavity is soon formed between the sides of the ice and the sides of the well, and as fast as the ice melts the vapour rises or is taken up by the air, according to its heat, and if in rising it gets into the current, which should be passing constantly day and night *over the bed of ice*, why it is carried away as fast as it is generated, to the great saving of the ice, and the cold caused by this evaporation is well explained in its effects on the ice by the American. But he missed the best part of the story. The whole top surface of the bed of ice ought to be rigidly excluded from the air, if that were possible, which it is not. That part of an ice-house, or ice, never begins to give way or melt till the sides are going very badly indeed. It is the vapour, rising from the sides and hovering over the surface of the ice, which melts it: therefore, very dry straw should always rest on the surface of the ice—a foot thick of straw there is not too much. I have scores of times found the surface as dry as tinder under that covering, while the sides all round were melting fast.

If straw could be kept dry between the ice and the walls of the ice-well it would be best to have it there of course. Now, this American invention was first set in motion by the hand which writes this in the winter of 1816 or 1817. I had a desperately bad house to manage then, and all we could make of it was to keep fruit and game a little longer than otherwise. The M.P. who had an ice-house built for himself in Cheshire all but above ground, by a London or by some architect, explained to me the natural law for keeping ice as it was told him, and as it proved to be in his new ice-house, and I got the old house altered, and put it right as nearly as I could, and the alteration did famously. The man-hole at the summit of the vaulted roof was opened, and was kept open with an umbrella-like top over it to throw off the rain. There was a well door into the vault from the side passage, and two doors in the passage itself, besides the outer door; all these doors were removed, and all the straw taken out of the passage, and the outer door was made self-ventilating, and thus a strong current of air got in, and then along the passage and in over the ice-well by the doorway, into it, and right out of the top of the dome, like

a whirlwind at times. After that the ice, of course, did not melt one-quarter so much as when it had been kept close.

Philosophers have been at work on the cause or causes of these terrible avalanches you read of in alpine regions. The cause of avalanches could be explained in an old-fashioned ice-house. There is but one cause, and it is the same, and must be so in all countries and climates, for it is a law of Nature, and that law is, that all masses of ice and of snow hardened to the consistence of ice on the surface, never melt by direct heat, or by thaw on the surface, but round the sides, as the sides come in contact with rocks or hill sides, but in the lowest part under the mass, if it were a mile through, the melting goes on at six times the rate it does on the outer sides, and when there is no melting at all on the surface.

The very same process which causes the destruction of whole villages in alpine countries by these avalanches, is at work to the destruction of our ice in ill-ventilated ice-houses—that is, confined vapour from the melting of the mass is the source of all that mischief. We have so far cured our ice-house, and it is just as safe, and, indeed, more so, except the expense, to prevent the largest avalanche on record from budging an inch out of its place high up on the mountain side. And, now, to conclude, I shall test the reader who is personally interested in the ice question, by asking him if he understands the drift of the story, and if he does understand it, he can very easily explain how a pending avalanche could be avoided—that is, could be made not to slide down the mountain, and I ask for his explanation.

D. BEATON.

THE ROCKERY AND ITS FORMATION.

I CONFESS it is not without some reluctance that I address myself to the task of replying to "A SUBSCRIBER" on the subject of rockwork, as amongst the many features of gardening this is one which has received the least notice from horticultural writers, and it is also one on which we see the greatest blunders made—in fact, a piece of really well-executed artificial rockwork is so seldom met with, that I am not surprised at our correspondent calling many of them "burlesques on Nature." Nevertheless, there are some noble examples. Elvaston Castle, Derbyshire, contains very good rockwork on an extensive scale, and arranged with a degree of natural ease and likelihood, forming a strong contrast to the quaintly cut objects in other parts of the grounds. Some very good rockwork has also been described at Redfern, in this county (Kent), but in this case Nature has lent some assistance; and at Belton, the noble seat of the Earl Brownlow, in Lincolnshire, there is an excellent specimen of artificial rockwork, aided materially by the river Witham, which traverses the grounds, and contributes a feature not often met with in such places; but the rockwork is well managed. A rustic-looking bridge spans the stream, which is made to appear as if issuing out of a cavern, and the river is no pigmy spring, but a stream about 20 feet wide, and apparently capable of driving a mill of 60 or 100-horse power. Nature, however, has not lent any further aid here than supplying the water, the ground being very low and flat; but the eye is so agreeably deceived, that a sort of rugged Glen has all the appearance of having been formed so by Nature, yet it is not so. The hilly slopes around Belvoir Castle, the noble seat of the Duke of Rutland, Leicestershire, also present some fair examples of rockwork, though not so good as that at Belton, as Nature had done all that could be wished for in the way of preparing a steep bill, thereby rendering artificial help a comparatively easy matter. Some other places I have seen also present some fair specimens of rockwork, but the majority are sad examples of overdoing the matter.

Piles of stone against the base of a purely Grecian or Italian residence is of all plans the most improper to form rockwork. Certainly, they are often laid with a degree of accuracy that disqualifies them for that name, although they often receive it nevertheless. A mound of earth in the midst of a dressed lawn is also undeserving the name of a rockery, although there may be stones stuck into it, but they are too often done in that fantastic manner, of which no examples are to be found in Nature, as every stone must have its angular point or edge upwards, a position we rarely find in mountain scenery—in fact, as I have above said, much of the artificial rockwork met with in most places is overdone or misplaced, so that a really well-managed piece is far from common. I think that at the Botanic Garden is good though not extensive, but there is nothing of the grotesque about it.

I believe in all the above cases that are instanced as being approved of, natural stones have been carried and arranged in the form they now assume, and I am told the floating down the river Derwent of the large stones used at Elvaston was a long and laborious job; but there are instances in which large stones have been dispensed with, and bricks and other substances fashioned into the shapes and sizes of such stones in a truly artificial manner. Of course, this requires still more taste and judgment than in the arrangement of stones ready made to hand; but when it is really well done, there is proportionately more credit at performing a feat in Nature by purely artificial means. Decidedly the best example in this way that I have seen is at Berry Hill, near Maidenhead, where a Mr. Noble had formed a very natural-looking piece of rockwork around a piece of water; the material used being, I suppose, brick coated with cement; but so well done that even the impress of age was given to it. It is some two or three years since I saw it, which, in fact, was while it was in the course of formation, but it struck me as looking remarkably well, and I have no doubt is now much improved; and the ingenious uses of cement and brick afford many parties the chance of giving their grounds the appearance of possessing huge rock stones, which they could not otherwise obtain except at great cost of transit. But there is, also, the great danger of this useful invention being also overdone by the formation of masses too huge to be expected to be natural, or forming them in a position at variance with that in which they are usually found.

Having given the above examples of artificial rockwork, as being the best I can at present call to memory as having seen, it is only fair to call attention to some cases in which Nature has already supplied the more genuine article. The rugged cliffs of many hills, not being of a chalky formation, present examples of naked and partly obscured rock as well as huge loose stones, which some terrible upheaving of the ground had hurled into their present position. These loose stones are sometimes of gigantic size. Fancy pictures to my eye the many times I have gathered Whortleberries amongst such stones in years long since gone by. Some of these stones in size and proportions equalling that of a moderate-sized haystack, and a piece of the fixed rock which overlies its foundation by a dozen feet or more was often honoured by picnic parties. Some industrious individual of a former age having formed a very large and well-shaped basin on its top, it received the dignified cognomen of the "Punch Bowl;" but its contents if ever full must have been measured by the hundred gallons. This, however, and other similar mountain features rarely form portions of dressed grounds, so I will pass on to some places where good examples of rockwork created by Nature form important features in the dressed grounds of which they form a part, and amongst the most prominent of such places Alton Towers is conspicuous. The Castle itself is perched on a high hill, or ridge, with a deep valley on two sides of it, and these valleys again rising up into abrupt rocky precipices, well clothed with becoming shrubs and trees, the natural rock presenting itself in that pristine grandeur which we may in vain attempt to imitate. Chatsworth also presents some good specimens of natural rock—in some places, however, showing the marks of the handiwork of a recent as well as a bygone age; and the rich and varied scenery of Mount Edgecomb, the seat of the noble Earl of that name, cannot well be surpassed. A noble harbour, a large and populous town, and coast scenery of every form, rocks and precipitous slopes, presenting themselves in every shape. In one instance I noticed a very good conservatory attached to the marine villa of the noble peer (not at the mansion of Mount Edgecomb), which was built against a cliff or permanent rock, the rock forming one side of it, and the interior arrangements showed that the exotics did not dislike their being in such close contact with the hard quartz, slate, and sandstone. In cases like this and others that might be mentioned, the formation of a rockery is a comparatively easy matter, and advice is needless; but in such places as are either destitute of stones, or where they only exist very sparingly, some means must be adopted to make the most of those that are to be had, and as examples of artificial as well as those of a natural kind have been adduced, I will now endeavour to describe, so far as I am able, what ought to be avoided as well as what ought to be done in the way of arranging a rockery so as to really, in some respect at least, to resemble what it is intended for.

If we examine the condition of loose stones, lying perhaps midway up an acclivity of more or less elevation, we will see that if that stone be a flat one—that is, if it be much greater in

length and breadth than it is in thickness, it will in ninety-nine cases out of a hundred be found lying flatways on the sloping bank; and if the stone be an irregular cube of considerable dimensions, it will be found that the heaviest, and consequently the largest, side will be the one that is on the ground. Now this is no more than is done when we handle and throw down much smaller stones. The same laws of gravitation regulate both: hence we may learn from this in what position we ought to place stones intended to imitate these colossal examples of Nature, and always place them flatways, or in such a position as resembles the one which Nature has given us specimens of. Secondly, whenever we observe stones in a state which we think has never been disturbed by Nature, although we are told there are really very few such, yet whenever we see them in an undisturbed condition we invariably see such as belong to the sandstone, limestone, and freestone sections, lying all more or less in a horizontal position. Slate, quartz, and I believe granite, are often found with an angle of elevation more approaching the perpendicular; but the mass of ordinary strata lie nearer the horizontal than the perpendicular line: hence we see the propriety of again copying Nature, and arranging what stones we have to represent our imitation in courses approaching to the horizontal line—or, if there be any deviation from the level, let the inclination once given be carried on throughout. A "dip," or diagonal inclination of strata, generally extends (in a natural way) over a greater breadth of space than is often under the control of the maker of a piece of artificial work. When, therefore, portions of fixed or permanent strata are wished for (and they are perfectly proper features in rockwork), let their "dip" (and they begun with (if the level line be departed from), be carried out with all that is to be done.

I have already explained that if the natural features of the ground to be operated on be level, it must be broken up in such a way as to show hills or elevations which are characteristic of a rocky district. This object will be easier attained if shrubs or trees abound—in fact, I hardly know how it can be well accomplished without the aid of these accessories. For an irregular mound on a plain surface shows in an unmistakable manner what it really is; whereas, if it were backed by a mass of shrubs, or trees and shrubs, one side of it would be so much concealed as to give the idea that the elevation was a natural one, which would not be the case if we could see round all sides of it at once, perhaps. In preparing the mound avoid all regular forms; at the same time do not digress too much to the other extreme by giving it too much of a tortuous character, which will also tell in like manner that it has been created artificially. A path may in some cases have an acute turning where a jutting stone obstructs a more direct way; but if that stone or something else in its stead did not exist, let the path, or whatever it may be, proceed in a more direct manner. In like manner in the formation of the groundwork for the rockery, let the outline be easy—all groundwork is so by nature. A long lapse of years has worn out all angular jutting points. And if we look at the most, nay all, the natural hills that I am aware of, we see the steepest portion of their sides is about the middle or halfway up, the top and bottom being always more or less concave or convex gradually merging into the level at both extremes. In like manner the artificial rockwork foundation ought to be the same, excepting in such cases as when a perpendicular cliff abruptly terminates the entrance.

J. ROBINSON.

(To be continued.)

AMARYLLIS FORMOSISSIMA PRODUCING SEED.

THE late Hon. and Rev. Wm. Herbert in his interesting work entitled "Amaryllidaceae," speaking of *Amaryllis formosissima*, at page 135, says—"No instance has come to my knowledge of its bearing seed in this country," and "numberless unsuccessful attempts have been made to cross it with other genera," &c. I succeeded several years ago in obtaining a most interesting pod of seeds from it, by crossing it with *Kurwinski*. I sowed them in a pot as soon as they were perfectly ripe, and I should imagine every one of them must have grown by the number which came up. They still remain in the same pot, but some of them have died. My old plants, their parents, have never bloomed since, to enable me to repeat the experiment, but I do not despair next season, as they have grown vigorously the last. *Martynia fragrans*, too, is said to refuse to bear seeds in this

country, but I have several large pods, both of the rose colour and the yellow, now hanging from the almost defunct stems. They somewhat resemble the seed-pod of the Balsam, only considerably larger.

I have succeeded in producing a fine spike of beautiful flowers from each of three of my old plants of Guernsey Lily this autumn, which I have never before accomplished.

Having to write to you, I thought I would just allude to the other trilles, and which I doubt not but other gentlemen have been able to accomplish as well as—THOS. R. DAVIS.

[Yours is the first instance to be put on record of Anaryllis formosissima having succeeded at all under cultivation. Karwinski we do not know, and if you flower it next April or May along with or without fecundissima, we should be very much obliged by a sight of the plant, not a cut flower. We would go a distance to see it. Do you know glauca or glaucum, and the tumbler or cytister, and is Karwinski like them, or more in the way of a Hippastera?

We have seeded *Martynia fragrans* often, and never heard it was difficult to seed. The seed-pod is most curious and most Lory for such a soft plant. Such "trilles" as yours are highly interesting.]

WINTER FLOWERS IN ROOMS.—No. 3.

I MUST now proceed to give some hints as to the final arrangement of the bulbs already started, for these growing bouquets.

The Hyacinth and Snowdrops, Scillas and Crocuses, that I put in last month have now splendid roots, long or bushy, as the case may be, and very pleasant it has been on several mornings lately to saturate the sand in the store-plate, and gently drawing out the well-rooted bulbs to arrange them prettily in glass and china dishes.

Many people may not know of the little glass milk-pans made by Messrs. Millington, and varying in diameter from 6 inches upwards. These seem to me to be made on purpose for such beautiful little groups; and from the first day they are planted, if not beautiful they are truly interesting. The dark green of some and the narrow pale leaves of others soon begin to unclose, and to show the colour of the not yet unfolded buds; and even though we must wait some weeks for the open flower, we have, so to say, an intimation of the pleasure they will afford us later. I am very fond of a most simple and most common plant—namely, that is to say, in its materials and in its easy tendency, but far from being half so common in the universal sense as I wish to see it.

For this commonest and most elegant of little floral groups, we take a round glass dish, a china old-fashioned tray, or even a common soup-plate. This dish has creased on it a little dry silver sand about half an inch deep, and then one very large corn of some very fine blue *Tucus* is drawn out of the nursing-plate, and straightway placed in the centre with four others round it. Then some paler Crocuses are added, and also white ones. But the white, it must be remembered, are often slightly streaked—far from a disadvantage in forming such a group. About five very dark, twelve of the next shade, and eight quite white make the quantity that I think does best, and it is indeed a most perfect "dish."

What would be more pretty in the depth of winter than such a plate raised in the centre of a drawing-room table, or standing alone on a marble slab? Crocuses, some say, are not worth growing indoors; but I suspect those people have grown theirs very badly, and are not, therefore, qualified to speak of the result. Crocuses must have full light, never get dry, and have their leaves well dusted with Diamond's Insect Powder as often as there is a symptom of green fly appearing, and then I think they will be well approved. Soup-plates hung up in wire baskets at windows are capital contrivances, turning them round each day. Managed thus they do not blow up. I should think it a great disgrace if the leaves of mine came up above the strong well-grown flowers.

For children nothing is so early and equal the charms of Crocuses and Scillas. They really see them growing from the first day they are planted.

I prefer, however, not mixing Crocuses with anything but Tulips, unless it may be Snowdrops. An edge of Snowdrops looks well with most things.

But I must proceed to Tulips. The little Van Thels not being so common, I will make such a charming centre for a dish

of white Crocuses. They should, however, have also a few Snowdrops dotted in amongst them.

HYACINTHS, SCILLA SIBIRICA, AND SNOWDROPS.

I have already spoken of these; but I beg to announce, for the benefit of those who are interested in others' progress, that my milk-pans are full of roots, and my Scillas and Hyacinth showing delightful points of dark green, while they require, I find, a large supply of water to be constantly added to the sand they grow in. Only two bulbs of mine have come to grief this year—two little Snowdrops they were; so, judging by the display of roots and size, I begin to think that the florists' lists are right in promising us such a splendid bloom this season.

The only other thing I must speak of to-day is the *Cyclamen persicum*. Both for its leaves and flowers, often so very sweet, this beautiful little plant is one of my greatest favourites. My own are very forward; but Messrs. Hooper sent me some the other day already out in blossom—quite covered, too, with beautiful little buds.

I know no plant in which it is more important to know of a good stock. Both last year and this I have bought some for trial, amongst other bulbs, which never gave one blossom and only two shabby leaves! And the price of those bulbs was exactly the same as that of the exquisite little gem now standing on my plant case—only on, not in, the case, for my plant case just now is at almost stove temperature; and the beautiful *Cyclamens* do charmingly in a window in a double pot, not very much watered but always in full light.

Talking of double pots, if Mr. Beaton had done nothing else for gardening, his late invention, which he calls stops and pots, would entitle him to a general vote of thanks from every one who possesses so much as a window-sill on which they want plants to thrive.

For my own part I think it delightful to have such a good and such a cheap appliance, quite as much for keeping as for growing plants—and for my new plant cases too—I can hardly tell yet the full value of the idea. I have written off immediately to ascertain the cost at which such things are to be acquired, and I hope ere long to see them in full use. But here my papers on winter flowers in rooms will merge into the use of the "Indoor Plant Case," a contrivance the result of which is simply to give hot-house flowers to those who have not even a greenhouse.—E. A. M.

TEMPERATURE OF WATER FOR STOVE AQUATICS.

I HAVE just finished a large stove, in the centre of which is a cistern for growing *Nymphaeas*; but I fancy my engineer has put too much piping in, so that the water will be too hot. Please, therefore, say what should be the temperature of water for the purpose above-mentioned.—W. K. H.

[If the tank is over 18 inches deep the surface of the water would be nearly boiling before the bottom was too hot for the roots. To get over that fix Sir Joseph Paxton hit on the plan of a constant waste of the hot water, and as constant a supply of cold water on the surface; that is the way at the Crystal Palace where *Nymphaeas* do remarkably well, and keep green till long after the New Year. If your tank is not over 7^{ft} to 8^{ft} on the surface long together the roots will take no hurt, as then the bottom of the tank will hardly be up to 60°; but 7^{ft} would be the proper pitch from April to October, and 6^{ft} for the winter months.]

FORCING STRAWBERRIES, KIDNEY BEANS, AND POTATOES IN A PIT. SCALE OF AN ACACIA.

I HAVE a six-light pit. There are three divisions separated by a four-and-half-inch brick wall. I have the command of top and bottom both from hot-water pipes. There are no stop-cocks in them, so that I shall be obliged to use them all at the same time, which makes it very awkward. I am to force Strawberries in one division, Dwarf Kidney Beans in the second, and Potatoes in the third. I want to have all three ready for table by the 1st of May, 1862. The Strawberries I have for forcing are Keen's Seeding and Prince of Wales. What kind of Potato and Kidney Bean would you recommend for forcing? and

would you recommend me to grow the Beans in pots, or to make a bed for them over the pipes? The bottom pipes are 3 feet 6 inches from the glass. I was thinking of making a chamber, so as to leave about 12 inches or 15 inches between the pipes and the bottom of the bed.

I have three *Acacia armata* plants, all the lower parts are covered with a kind of mildew. I have enclosed a few leaves for your inspection.—G. S.

[There is no difficulty or awkwardness in the management of your pits. You may have a chamber if you like above the pipes, but we would put some clinkers and brickbats, and then some sweet dung and leaves in the two parts designed for Beans and Potatoes, and soil above them if crops are to be planted out, or if in pots plunge the pots, to give a little bottom heat. Whether you have clinkers or not in the Strawberry division, the plants will do best on shelves at an early period. As soon as the fruit is set you might plunge the pots also in a bed of leaves, with rotten leaves on the top. In either case the plants should not be more than a foot from the glass. We would also alter your arrangements, and place the Beans next the boiler, the Strawberries next, and the Potatoes farthest off. If you are new to the work, the Beans might as well be in pots, five or six in a twelve-inch pot. China dwarf and Sion-House-forcing are as good as any, and the Newington Wonder, a small Bean, if it is desired to cook them whole. The Potatoes may either be in pots or planted out, two sets in a similar-sized pot. Nothing, in our opinion, beats the Ash-leaved Kidney now. You do not tell us how the bottom heat is given, whether the top pipes return, or you can give bottom heat independently of top heat. If the plants are in pots, you can regulate the bottom heat to a nicety, by raising the pots a little; but in either case if well managed you are not likely to have too much of it. The Beans should be sown about the beginning of March. It will be best to be time enough in case the weather should dull—any, therefore, last week in February. Bottom heat from 70° to 80°, top heat at night from 60° to 65° by day, from 65° to 75° in sunshine. Strawberries, begin with from 45° to 50°, increase from 55° to 65° when in bloom, and from 65° to 70° when ripening, and a drier atmosphere. Potatoes commence with bottom heat of 70°, and top heat of 50°. The top heat from artificial means should not be higher than from 55° to 65°, with a rise from sunshine, and plenty of air given. With your divisions there will be no difficulty in all this. You must first give more or less air in proportion as you want a low or a high temperature. In such a pit we have grown Cucumbers in one division, and Geraniums in another. If you can protect your Strawberry plants from heavy rains, frost, &c., during winter, all the better for them. See "Doings of Last Week," in last Number.

Your *Acacia armata* is smothered with white scale. If all is as bad as the sample, cleaning the whole plant is impossible. We advise cutting off all the twigs, leaving only the bare skeleton, then wash and scrub that with soap and water, when dry rub it again all over with a thin solution of glue water, and let the plant stand in a shed for a week. Then scrub it again with water about 100°. This will pretty well destroy every insect and egg left on the bare skeletons. You may then place the plants below the stage in the greenhouse, and see that the pots are not quite dry. Next spring they will break all over and furnish you with healthy shoots. If you could give the plants a little heat in a forcing-house in spring you will get the shoots forward enough to be ripened, and bloom the following winter and spring.]

OLD APRICOT TREES UNFRUITFUL.

CALECOLARIA SEEDLINGS—SCARLET GERANIUMS IN A FRAME.

I have some Apricot trees from fifteen to twenty years old, they do not bear very well. Do you think them too old to root-prune? If not, how close should the large roots be cut?

I have some *Calceolaria* plants from a sowing last spring, I find they are starting for flower. Do you think they will flower as well next month as in the spring? Or should I pinch them back? I have them in a cool frame with plenty of pot room.

Do you think Tom Thumb Geraniums will stand the winter planted close together under a glass frame?

Will Variegated Mint stand in the open ground, I mean the sort that is used for edging flower-beds?—T. H. J.

[We should prefer raising the roots of the Apricots and

bringing them nearer the surface—say 6 inches, and this would enable you to go within 18 inches of the bole and see there was no strong tap root. We are supposing that the trees are barren from extra luxuriance, but you do not say so. Perhaps the wood is too thick, and left dangling from the wall so that the sun cannot get at it.

The *Calceolarias* will bloom in a house averaging 15°; but as the weather may be expected to be dark they will not bloom so well as in spring. Better select the forwardest, and stop the others as you suggest: if the pots are full of roots, give a small shift now, and a larger one after Christmas. Too much pot room in November and the beginning of December is apt to bring on damp, more especially if you have only a cold frame or pit to keep them in.

The Tom Thumb may be kept safely under a glass frame, but not if a person goes to sleep on a frosty night, and gives no covering, or allows the glass sashes to be a fixture for weeks in dull damp weather.

The Variegated Mint is quite hardy, and does best when cut into small pieces and planted every spring. To make doubly sure, however, you may put some in a pot or shed; but the frost last winter never touched it, and after that it is likely to stand anything.]

THE MUSHROOM AND ITS CULTURE.

THERE are few cultivated articles in which greater uncertainty exists than in a crop of Mushrooms when grown under artificial treatment; for uncertain, and in some respects capricious in a wild or natural state, they are still more so when we endeavour to obtain them in a season the reverse to that in which they are produced naturally: so that, in spite of all our care, it sometimes happens that failures occur when least expected; and, on the contrary, it sometimes happens that a very careless putting together of materials is rewarded with success. But the latter case is the exception, the rule being that, in a general way, judicious management will bring a good crop (and it often happens to be so), and a little pains taken to secure this will in most cases be rewarded. And as the means and appliances for this desirable result are far from being of difficult access, the following instructions will usually prove successful.

Mushrooms, as is well known, grow best in the mild moist evenings of autumn before frosts set in, and before the ground gets cooled down to the winter temperature; but, in fact, as long as sharp frosts keep away, there will generally be Mushrooms in those pastures where they are wont to grow, and though the days may be mild and warm, the growth of the Mushrooms is greater at night than during the day, thus proving that darkness is one of the conditions necessary to their doing well. Certain meadows have the character of producing Mushrooms in greater abundance than others, but it is difficult to describe what kind of soil suits them best. A loamy soil overlying limestone is often a good place for them; but the opinion of old people residents of the County is of more worth in determining the whereabouts of a good Mushroom-field than any learned disquisition on the subject. But as this is foreign to the subject of growing Mushrooms by artificial means, it is needless proceeding further in the matter than to show that one of the conditions of their growth, "darkness," may be copied in the artificial treatment.

The first thing to do in the way of preparing materials for growing Mushrooms is to obtain a quantity of fresh horse-dung that has not been heated. This latter condition is absolutely necessary, and where there is a difficulty in obtaining a quantity this way that has not been heated, it is advisable to make some terms with the stable-keepers, and remove the dung every day, spreading it out not more than a foot thick on the floor of some open shed, or it might be under a tree, or anywhere secure from rain; turn it every day or so until it is pretty dry, and when a sufficient quantity is ready a bed may be made. Generally speaking, the end of September is as early as most people make Mushroom-beds, and from that time up to Christmas they may be made in succession as wanted. About six weeks after being made is as soon as Mushrooms may be expected, sometimes they come sooner, but often much later. The situation for a bed is not material—any place not too damp, but secure from rain and frosts will do. One of the best Mushroom-beds I ever had was under a tree covered up pretty thickly with litter to keep out the frost; and this bed answered admirably, producing abundance of Mushrooms in long succession. The bed

was formed as a ridge with a base of about 5 feet and as steep as it could well be made, with the short loose dung trod firmly up to the ridge. Being spawned and covered with mould in the usual way, well beat over, and covered up with litter, it received no further attention than uncovering and gathering the crop, and a heavy watering towards the end of the season to revive it again, which it did for a time. But it is needless to say that for an out-door bed like this more dung was used than would make several shallow-beds in a well-constructed Mushroom-house. A lean-to-shed is also a pretty good place for a bed, and if it be a very cold place a greater proportion of dung must be used than if it were warm; somewhat like 15 inches of solid dung well trod on will not be too much, taking care to have the dung tempered by exposure and frequent turning before making up, and in such a place a good crop may be expected. A cellar is also a very good place for a Mushroom-bed, and certainly better than any open airy place; for Mushrooms seem to like a still atmosphere—almost stagnant in so far as regards motion, so that a large airy apartment, however useful for most other things, seems unnecessary, if not absolutely hurtful, to the Mushroom; so that amongst the many places we hear of their being produced, in very exposed places are the most rare. Many years ago I saw some excellent Mushrooms that had been grown in a coal mine some 300 feet or more below the surface, where horses were kept for use, and remained continually so long as they were healthy. Old corners in a disused stable are very good places for Mushrooms, the conditions of their growth being the same in all places; well-prepared horse-lung and mould, with a little spawn to set the fungus going, and a close confined atmosphere rather moist than dry are all the conditions necessary to insure success.

Where there is the advantage of a Mushroom-house with shelves 9 inches or 10 inches deep, with an application of fire heat when needed, the difficulty and uncertainty of obtaining Mushrooms are very much reduced, and beds may be formed in succession, and spawned so as to obtain a crop all the winter. Dung well sweetened by turning may be formed into beds, and as treading is out of the question in such places, a wooden hammer, like a carpenter's mallet, must be used, as firmness is an essential qualification to make the beds do well.

If means be taken to prepare the dung before using there will rarely be any more heat than is requisite to make the spawn spread; but if any doubts exist on this head it is better to allow the bed about a week to ascertain this point, and the spawn, which is often in lumps like bricks, may be broken into pieces about the size of an ordinary Potato, and inserted over the bed at distances of 6 inches or so apart. Generally, if spawn has to be bought, it is used sparingly; but if the grower make it himself, it may be used more freely. Fill up the holes and beat the bed well when it is spawned, and in a day or two after cover it with leamy soil fresh from a pasture field—I do not like the soil from tillage ground so well—beating the surface smooth with the flat side of a spade completes the job, except covering it over with litter; and keeping the surface frequently sprinkled with water will assist the spawn in spreading, and when the Mushrooms appear give a little more water, but no heavy waterings until the bed shows symptoms of languishing, when it must have a reviver by a good heavy watering. When the spawn begins to run care must be taken that it does not exhaust itself by running amongst the loose litter used as covering; if this should show symptoms of stringy whiteness in it remove it altogether, and substitute fresh litter; but moving it occasionally will prevent this in a great measure, and, if possible, to let these operations be done on mid days, without-door or open shed beds, as high drying winds, or clear frosts, are pernicious to this vegetable. Most other conditions will suggest themselves to the operator; but the subject of making spawn and some other features bearing on this eccentric crop will be treated of in another communication.

J. ROBINSON.

VARIEGATION—IS IT DISEASE?

WHEN I first opened this subject in your pages, it being one in which I took great interest and had been for some time making observations, I little thought it would lead to such an interesting discussion. As I lay on a sick bed and read the various remarks of Mr. Beaton and others, whose opinions carry weight with them, I felt pleased that I had introduced the matter, as I now find many are watching with interest the discussion to see the issue; and, now, Mr. Anderson Henry has entered into the

arena, whose experience, practice, and observation would lead one to take in all for indisputable facts, I feel it is no light matter to contest against such men. And here allow me to say in reply to Mr. Anderson Henry's question, that "NICKERBOR" has a reason why he does not write his name in full—he is not ambitious of seeing his name in print.

Mr. Anderson Henry, in his article, page 11, says, "NICKERBOR" can be by his experiment—*i.e.*, the peculiar cross mentioned there, 'maintain nothing against disease being the cause of variegation.'" Now, the contrary is the fact. I do distinctly maintain that by the experiment Mr. Anderson Henry clearly proves that there was no disease; but if, as Mr. Beaton suggests, that the subject lies in the meaning of the terms used there is an end of the subject, it is only play upon words, and not as I understand the matter, which is to try and find out the cause or causes of variegation. I admit that there is more than one cause, and if the doctrine of Mr. Beaton is sound, that it is caused by the pollen of the male parent; and as Mr. Anderson Henry endorses the same view, which is in opposition to the theory of Dr. Morrens, at page 383 of your last year's volume, where he observes that these observations naturally lead the mind to seek in the effect of respiration the cause of the phenomena of variegation. I still contend that we have not sufficient evidence to prove that these are the only causes.

But let us take the matter up in order. Mr. Anderson Henry says, "I can maintain nothing against disease being the cause of variegation, in his experiment, which is said to be caused by the pollen of the male parent.'" Now, allow me to ask why is not the progeny of the inverted cross, which is described as having waxy, pale-coloured blooms with plain ordinary green leaves—why is not that called disease? That disease is in the flower, if it is disease in the other case; so in this the one is developed in the flower, the other in the foliage. We all well know that disease in plants is of frequent occurrence, and that plants are subject to many diseases who can or does doubt? But who ever saw a thoroughly diseased plant show its disease in splendid variations of colour in the same leaf? hence we have the result of two inverted crosses—perhaps unprecedented; and, yet, only one of the two is called diseased. How did that pollen become diseased? Would the most powerful microscope show it? Or how are we to know that that was diseased? It is only a supposition, and for anything which has yet appeared, the variegated progeny grew well, and to all appearance to all ordinary observers as healthy as "Old Tom" himself appears at the present day, despite his numerous progeny; therefore, I contend that instead of a disease it was a chemical change in the component part of the plant developing itself in the leaf, as much as in the first cross in the bloom. There was a chemical change in the colour, the white and scarlet mixing; and, as a natural consequence, the bright scarlet was decreased by the white. I am not going to attempt an explanation of the phenomenon; but from the observations I have made during twenty-five years practice, I feel persuaded that it will be found to result from the soil, and the water absorbed by the roots.

Having just read Mr. Beaton's article in the current Number, I find he holds views something similar, at least so I deduce from his remarks, "that after growing the two for one season in his soil he could get every seedling from the same cross as Mr. Anderson Henry as true as seedlings from Tom Thumb." I saw a few days since a lot of seedling Geraniums, the progeny from a cross of two variegated seedlings, and more than nine-tenths were plain green-leaved, or green with a dark-zone. Will Mr. Anderson Henry be kind enough to explain how two "diseased" or variegated Geraniums, if it is disease, should produce a healthy race? for I understand the matter correctly, according to holders of the disease theory, any variation or departure from a green foliage is disease. Has it never occurred to many of your readers that during the last few years, since chemistry has been studied and artificial manures used, and that with high culture we have had an immense quantity of variegation from the original varieties, not only Geraniums, but other plants, both exotic and indigenous, and that when once a variegated variety, or, as is often the case, a discoloured variety is introduced, how soon we have a race of variegations of various forms, that same family. Look at the handsome Begonias, Caladiums, &c., and who can say how long ere we shall have an inundation of variations in Ferns? We have now of Pteris three variegated varieties, and who can suppose that our successful raisers of the various forms of Ferns will not try their hand, and soon have many more beautiful-marked ornamental forms? It is, perhaps,

not generally known that madder given to an animal for a time continuously will dye the bone and hair of such animal; and if such is the case in the animal kingdom, may we not reasonably expect that there is to be found some chemical compound, or dye, or acid, which would dye or blanch the whole or parts of a leaf, or leafstalk or stem of a plant? May not there be a chemical action going on in the atmosphere or soil, decomposing or partially decomposing the water in such soil which is absorbed by the roots, and thus cause variations in a way we may not be able to explain, but which may, perhaps, be borne out by experience? Let us all enter on a series of experiments, in whichever way we may think is the most reasonable according to his point of view, whether by chemical experiments or by crossing with pollens from various flowers, carefully noting the experiments and results, and we shall as surely arrive at a satisfactory conclusion as to the cause or causes, as the chemist or colour maker in the dye or printworks, of Manchester, arrives at the reasons why or wherefore certain gases, drugs, or chemicals, cause a certain shade of colour.

I shall not dispute the point as to variegation causing dwarfness, that is a point I shall not interfere with; but I do not think in every case that will hold good. Neither will I go on any further, as I shall be taking up your pages too much with what will, perhaps, be thought by many nonsense. I had intended to contest the matter further on other grounds; but enough at present. I shall try a variety of experiments with a view of ascertaining if variegation cannot be, and is not caused more by absorption by the roots than by respiration or pollen, be it either male or female parents, not only in Geraniums but other plants likewise; and if I can produce any variegation or variation by artificial means, I will note the results and submit them to you, as my only aim is to elicit truth. We see and admire certain effects, let us not rest until we trace the cause to its origin.—NICKERBOR.

CULTIVATION AND MANURE AS FERTILISING AGENTS.

By HENRY TANNER, Professor of Agriculture, Queen's College, Birmingham.

(Continued from Vol. I., page 421.)

THE tillage of the land is designed to prepare it for the germination of the seed, and, finally, the perfection of the crop. For the accomplishment of the former the land has to be brought into a state favourable for the germination of the seed, or, in more general terms, I should say into that free and loose condition which is known to be so necessary a preparation for sowing. This condition, which is favourable for the first growth, is equally so for the subsequent perfection of the crop. The operations by which this result is gained consist of ploughing, rolling, harrowing, &c., and these are very beneficial in increasing the fertility of the land—in fact, we may view them as so many means for exposing the various parts of the soil to the action of the air, rain, frost, and light.

I have already stated that the carbonic acid and oxygen carried into the soil promote the chemical changes which awaken the dormant ingredients of the soil, and bring them into active exercise. In like manner those parts of the soil which are upon the surface are exposed to these chemical changes, and thus a ceaseless action appears to be going on between them. This change is one by which the mineral matter of the soil is acted upon; but, in addition to this, we have other changes produced—viz., the decay of the organic matter of the soil; for the air and moisture promote changes in its character, and thus render it valuable for promoting vegetable nutrition. It is, however, worthy of note that, whilst the organic matter of the soil is undergoing decay or decomposition, this change favours and promotes the conversion of the mineral matter of the soil from a comparatively useless state into a condition suited for the wants of our crops. Any process or operation which stirs the soil, and brings fresh portions under the influence of decomposition, promotes these changes in the organic and the mineral matter of the soil, thereby rendering them available for the nutrition of our crops.

In this manner the stores of the soil are opened up and rendered useful; but I have now to show that tillage operations not only accomplish this desirable result, but they also prepare the soil for abstracting from the atmosphere fertilising matter. The value of ammonia as a manure is well known, and upon its action the beneficial character of many of our manures is based.

It is an expensive manure, but still its judicious use is remunerative in a very high degree. We send many thousands of miles for a large portion of our supplies; yet it is found in the atmosphere floating around us, and is there present in a condition available for the use of vegetation. It is not necessary or desirable for me to refer to the sources from whence it is supplied to the atmosphere; it is enough for us to know the valuable fact that there are abundant stores prepared for the cultivator who is ready to receive a supply therefrom. It is with great pleasure that I refer to a very valuable contribution to our knowledge of the principles which regulate agricultural practice by Professor Way. It will be found in the sixteenth volume of the Royal Agricultural Society's Journal. He there proved the presence of nitric acid and ammonia in the atmosphere; that these bodies are removed from the air in two ways—by the absorptive powers of the soil, and by the rain dissolving them and carrying them into the soil. He very judiciously remarks: "The atmosphere is to the farmer like the sea to the fisherman, and he who spreads his nets the widest will catch the most." It is not that all land derives equal advantage from this magazine of wealth, but land receives and profits just in proportion as the industry and intelligence of man render it capable of drinking in these fertilising matters.

Thus you observe there are two channels through which the nitric acid and ammonia of the atmosphere become introduced into the soil—the one by the direct absorptive powers of the soil, and the other by the intervention of rain bringing fresh stores within reach of the soil. With regard to the former of them, I may say, that although it does not come properly within the limits of the subject under our notice, still the practical connection is so manifest that I shall not refrain from going into some brief notice of it; but before doing so, I shall notice the agency of rain. This must be viewed as an assistant agent which gathers the accumulations in the atmosphere, and brings them within the influence of the absorptive powers of the soil. If, therefore, such rain passes away on the surface without entering into the soil, it is manifest that its services are lost: hence land, which by natural or artificial drainage allows the rain to pass through it, carries into the soil its hidden treasure, which in any other case would pass away to some other recipient, or to the nearest stream. The value of its assistance to any agriculturist simply depends upon its services being accepted and turned to some useful account, or else rejected, and its agency wasted.

We may now notice the absorptive powers of our soils. The researches of Professor Way (published in the "Journal of the Royal Agricultural Society," vol. xv.) are of the deepest importance to agriculturists. I will, therefore, briefly bring before you the results of these researches. It was observed that when a solution containing ammonia, or other alkaline salts, was passed through a portion of soil, the soil separated the ammonia from the liquid, preserving it from being again washed out of the soil; and this action was finally traced to the presence of bodies in the soil known as the double silicates. A silicate is a compound of silica with another body—say, for instance, silica and soda produce a silicate of soda; but the double silicates are very peculiar, for in these we have silica combining not with one body, but with two bodies—for example, there is the double silicate of soda and alumina, the double silicate of lime and alumina, and a third, which is the double silicate of ammonia and alumina. But you will observe that alumina is present in each, and the only difference is that soda is present in the first, lime is present in the second, and ammonia in the third. In most soils we find these double silicates present, but their value varies very considerably. We may now observe the difference in their character and mode of action. The double silicate of soda and the double silicate of lime are each capable of separating ammonia when it is dissolved in water, but the double silicate of lime alone has the power of separating ammonia from the air; the double silicate of lime is, therefore, decidedly the more valuable salt of the two. The double silicate of soda is readily converted into double silicate of lime when lime is added to the soil: consequently, the addition of lime to the soil renders it competent to absorb more ammonia from the atmosphere, and thereby gives it greater powers of acquiring fertilising matter than it previously possessed.

In addition to this benefit, another desirable result has been attained by the use of lime—viz., that, as nearly all soils contain ammonia in them in a dormant state, the use of lime displaces part of this ammonia, and thereby this fertilising matter becomes available for the plants growing in the land.

Thus it is seen that in the soil there are bodies capable of

separating ammonia from the rain as well as from the atmosphere, and afterwards preserving these fertilising stores until required for the crop. We have in the use of lime a double advantage—it not only gives the soil superior powers of acquiring that valuable fertilising matter—ammonia, but it also renders the existing stores of dormant ammonia ready for active service in promoting vegetation. It is, however, of no practical value to us having in our soils the means of accumulating fertilising matter, if, at the same time, we place it in a position in which this power is rendered inoperative: consequently, we have two means by which to promote the accumulation of ammonia in the soil, and these are—1st, increasing the capability of the soil to absorb ammonia; and 2nd, giving the atmosphere a free access to the soil, so that these powers may come into full operation. The addition of lime to the land has, in this respect, a double action—viz., it sets part of the ammonia in the soil free, and is available for promoting vegetable growth; and it also renders the soil more competent for accumulating a store which will maintain the fertility of the land, and thus we have in the use of lime as a manure a valuable means of valuing the first requirement—an increased absorbing power. The attention may now, however, be advantageously directed to the facilities for the increase of these powers, and these are manifestly twofold—viz., the exposure of the soil fully to the air, and the passage of rain through the land. The tillage of the land is, therefore, just the agency required to accomplish this desirable result: for, as I have said before, the inversion, stirring, and crushing of the soil by the various operations of ploughing, cultivating, harrowing, and rolling, each and all promote the exposure of fresh portions of the soil for atmospheric action; and whatever capability is possessed for the secretion of ammonia, the soil is thus furnished with the opportunity for its exercise.—(*Transactions of Highland Society.*)

LEVEL AND DISTANCE OF HOT-WATER PIPES FROM FLOOR.

Will you oblige me with your opinion, what the height the hot-water pipes (four-inch) should be from the floor in a small greenhouse? Also, if the pipes should be laid level? Size of greenhouse 14 feet by 10 feet, but may be enlarged.—W. M. LIVERIDGE.

[The pipes may be placed at any height most suitable, but if they are from 4 inches to 6 inches or more above the floor it will be high enough so that they clear it, and there are sound supports against the joints. We think the heat is given off better when the pipes are laid down side by side, instead of above each other; for instance, if three pipes are needed for such a house, two flows and a return, though one of each would do then, we would place them so , instead of , but then in a fourteen-foot length we would raise the flow-pipe 2 inches or 3 inches to the extreme end, and then the return-pipe would dip that much backwards.]

THE OCTOBER JUST ENDED.

THE month that is just past has been, in many respects, one of the most remarkable (for October) on record. The preceding two months having been fine, dry, and hot, the ground had become very dry, when it was refreshed by some useful rains the last week in September; and warm days, and, what was more remarkable, warm nights following, the growth of Grass, Turnips, and most kinds of garden produce was very rapid, and the warm weather of the day days continuing up to the middle of October, when on the 15th of that month the thermometer in the shade reached 79°. Several preceding days were 76°, 75°, and 74°, while the nights indicated 51°, 53°, and 52°, as the lowest it had fallen to. This extraordinary warmth was, perhaps, more favourable to the vegetable kingdom than healthy to the human race, the close, oppressive heat of October being worse to bear than a July's sun, but after the middle of the month it became a little cooler; but it was not until the 27th that the thermometer fell below 60°, and on that evening, and also on the 28th and 30th the thermometer registered respectively 39°, 39°, and 38°, and the lowest maximum point for the day being 55° on the 28th.

It is certainly very unusual for October to pass away without any appearance of a frost. Generally we have three or four, and sometimes as many as eight frosty nights in October. This season none. The natural consequence of so mild an autumn month has been highly favourable to the various kitchen-garden

crops. Scarlet Runner Beans have not yet yielded their last picking, Celery has been growing fast, and all the Cabbage and Broccoli tribe have grown almost out of character, particularly Brussels Sprouts, and the various families of Greens. The fine, warm, sunny days have also matured the buds of fruit trees, so that a plentiful supply of blossom, if not of fruit, may be expected next year; while in the flower garden the mild, warm weather has been equally beneficial. Geraniums, which the rains at the end of September had in a measure deprived of their bloom, came now flowering afresh, and about the 21st of the month were as brilliant and gay almost as at the very best part of the season; but such unusual, I might almost say unnatural bloom, was not destined to be of long duration—about sixty hours. Heavy dew and slow, hazy rain were more than they could bear, and many of them drooped to rise no more. Tropaeolum, which also bloomed remarkably well, stood the damp better, as also did Lobelia, Salvia, and Verbena. Some plants of Verbena Purple King, in ribbon-borders, looking quite gay at the end of the month, while the apparent mildness of the weather rendered it unnecessary to disturb such plants which it is customary to take up, as Geranium Golden Chain, and others, until the very last day of the month, and some left still later. Most other flowering plants also look well, and the fine autumn will certainly do much to remedy the evils of the severe winter of last year, and such plants as Magnolias have recovered their wonted health, and I noticed a flower on one, which is, perhaps, far from a common thing the present season. Several Yucca gloriosa have also run up into flower in the past month, and I should say it must have been an excellent time to save seeds of late-ripening things; while patches of Geraniums, of the white variegated kind, look more gay than at any time during the season, especially such kinds as do not lose their leaves in the autumn, and it is only such kinds that are really worth cultivating.

To those who are interested in meteorology, the following notes may be of service:—

Rain during the month of October, 1861, at Linton	... 89 inches
Do. average at Linton during the last seven years	... 2.84 inches.
Average maximum thermometer ranges in Oct., 1851	67°
Average ditto of last seven years	... 57.4.

With the exception of January, October has been the driest month this year. Neither has there been much fog, and very little high wind. The weather, in fact, being more in the character of late summer than autumn. Some winds on the 30th rendered the tumpike dust troublesome, an unusual occurrence at the end of October.—J. ROBSON.

A LONG-KEEPING ORANGE.

ON reading your account of the Osage Orange, it brought to my recollection a circumstance that happened twenty-two years back. I was in the Botanical Gardens, Damporee, near Poona, Bombay, when the gardener gave me an Orange from a tree obtained from the Island of Johanna, in the Mozambique, which had the rare quality of keeping good and sound six months. It was of very large size compared with what are sold in England, and a most delicious fruit. I only mention the circumstance as it is possible it may be of a hardy sort.—A. S. F.

MR. ROBSON'S REMARKS ON FRUIT CULTURE.

I THINK I have managed to wade through those weary columns in No. 31, written by Mr. Robson in defence of his stand-stillism, and I have in vain tried to comprehend his motive for writing them. If he could have given his own experience—say for the last seven years—in the culture of orchard-house fruit, and why he had failed, if failure had taken place, or if he had during that space of time paid visits to Sawbridgeworth, to Trentham, to Reigate Lodge, to Mr. Crowley, and numerous others near Alton, to Basing Park, to Audley End, &c., and have given a fair unprejudiced opinion of how the system worked, he would have been a real benefactor to your readers. Instead of this he writes about old recollections of the system not being new, and of old things he has seen, of old failures from bad practice, then sneers at the very excellent name given to the culture of fruit under glass, does the same at some other mode of cultivating fruit trees in gardens (I suppose he means the removal or root-pruning system), and in fact, gives your readers but a poor idea of his capabilities. I presume that living in Kent, with the finest sites

and soil in England for orchards, and with orchards so barbarously planted and managed as to be a disgrace to the county, he has imbibed, unknown to himself, a set of stand-still ideas with regard to fruit culture.

I paid, a few weeks since, my annual visit to Kent, where I always spend a few days rambling about that agreeable county, and there met the well-known author of the "Fruit Manual." We visited in company some of the orchards diverging from Greenhithe to the south, occupying a large tract of country with a fine soil, and abounding in excellent sites for orchards.

What did we see but backwardness of fruit-tree culture almost incredible? In large orchards, on one side might be seen some old decaying Pear and Apple trees; on another side some young trees thrust into the turf and trying hard to live and grow. No arrangement of trees in regular rows, each row of one sort to facilitate gathering the fruit as they ought to be. No pruning, no method, but all confusion confounded.

Mr. Robson who, I believe, has told us how to manage a miniature farm (a miniature fruit garden he seems to look at with distrust), ought to have enlightened the Kentish orchardists; but I am quite inclined to think, that living near one of these antiquated orchards would bring in a sort of Rip-Van-Winkle feeling. I looked at the mossy, decayed stems of the old trees, got into a reverie about the progress of age and decay, thought about Mr. Robson and his Crystal Palace fruits, till I had fashioned him into a nice mossy old Apple tree, giving but little fruit, and not making much progress. I have a firm belief that I also should grow mossy if I lived in such a neighbourhood, and so I freely forgive him for his rather prosy style, and advise him as a friend, to remove from such a stand-still district.

One word more. Mr. R. says, alluding to his own remarks on the Crystal Palace Show, "I did not assume to describe all that was at the Show." No. He went there with one eye closed and the other not open, to see what was unfavourable to his peculiar views. "None are so blind as those who will not see."—CONSTANT READER.

STRAWBERRIES IN ORCHARD-HOUSE.

PUTTING ITS TREES OUTSIDE.

I HAVE this day (Oct. 24th) removed from the garden to the orchard-house two hundred pots of Strawberries, May Queen and Keen's Seedling. I have done so for the purpose of keeping them dry, the plants are fine. Am I right in so doing? and may I continue them in the orchard-house until the time for forcing? I have removed my orchard-house trees into the garden for the purpose of ripening the wood. Shall I be right in allowing them to remain in the garden for the next two months?—A SUBSCRIBER.

[You have done right with the Strawberries. The pots had better be plunged in earth or leaves, and will need no water unless they show signs of flagging.

If the orchard trees are not ripening their wood we see little use in putting them outside now. The propriety of keeping them out will depend on the sorts and the weather. If you should have a severe frost before two months, we would rather have them inside and the pots protected too.]

THE MUSCAT HAMBURGH GRAPE.

You are evidently under a very erroneous impression about the Muscat Hamburg Grape—at least I should say so by your commendation to "E. C." at page 466, on September 10, and which has only been shown to me by "E. C.'s" gardener calling here the other day to see our Grapes.

I am sure you wish to be honest, and not condemn a good Grape. Come and see it growing here—judge for yourself whether it merits the censure you have heaped upon it. We have it growing in, no doubt, the largest orchard-house in England (105 feet by 41 and 20 feet), growing and fruiting fine, in a border made only fit to grow Mangold Wurtzel; certainly no preparation further than that—not a particle of heat beyond the sun's rays. The fruit sets well, swells well, colours well, and ripens well, and what more do you want? Do justice in all things.—JAS. FINLAYSON, *The Park, Leightonstone.*

[We are most happy to hear your statement about the Muscat Hamburg Grape. It is a Grape we have always had a strong liking for, and it is one which, when well grown, is unsurpassed

in flavour; but we have seen it so frequently set badly, and heard so much of its having that bad habit, that we give what we believed to be our best advice. In the forcing-pit of the Horticultural Society this season it set very badly; while in the large vinery it set well, though the bunches were not large.—EDS. J. OF H.]

PITS HEATED BY DUNG IN SUMMER AND HOT WATER IN WINTER.

I WANT to put up a range of Meldon-pits to be heated in summer with dung, and in winter to keep bedding-plants in. Can I have a due to exclude frost in winter, and the dung for bottom heat in summer? And are the pits best sunk or raised?—AN IRISH SUBSCRIBER.

[If you can depend upon a dry bottom naturally, or by drainage, then the pits will be best sunk for at least half their depth; if you cannot depend on that dryness it would be best to build them on the surface, and use hollow walls instead of solid ones. We have lately stated how such a pit should be heated altogether from a due. If you contemplate dung for bottom heat in summer the due had better go along the front; and then, in winter, instead of leaving the manure in, it will be best taken out, and a temporary stage for the plants put in that you can raise or sink at pleasure. Below that stage many things as Fuchsias, Dahlias, &c., might be kept in winter, whilst the young growing plants were on the stages.]

LILLIPUTIAN DAHLIAS.

AT page 49, line 19, your printer has made a mistake which please to correct. It should read 27 inches high, not 37 inches, as there would be no good proportions between height and circumference in good Celery culture.

Last autumn the new class of small-flowering or Pompon Dahlias were incidentally mentioned in THE JOURNAL OF HORTICULTURE, and as they are pets of mine (I suppose on the principle of "Little minds like little things"), and, as I believe, deserving of extensive culture, permit me to call attention to them, as I feel persuaded that when more generally known they will be appreciated and grown, and I do not despair of seeing ere long prizes being offered at our horticultural exhibitions for them in stands as other Dahlias are, and in pots, where they will look well and be admired for their dwarf habit and their free-blooming propensity. They are, many of them, good in outline and proportions, depth of petal, and have a good centre. For vase culture they are unsurpassable. For front rows of borders, or small beds, they fill a gap in the flower garden. For bouquets or cut flowers in drawing-room they are alike suited, and Mr. Summers (Spergula Summers), the manager of the Crystal Palace Nurseries, Sydenham (Messrs. Carter & Co.'s), is trying some experiments with them, which if successful will make us open our eyes and wonder. If it is true, I must not betray his secret at present, but the man who so successfully handled Spergula is not the man to sit down and fold his hands in despair at a little failure, should it be so. What should we say if in the early spring months we had Dahlias in full glorious bloom in our rooms and conservatories? Well, patience, and we shall see. Let some of the floral committees offer good prizes next season for the best twelve distinct varieties in eight-inch and eleven-inch pots in full bloom, and let them be judged by the most and best-shaped blooms on the respective plants, keeping the condition of the whole collection as to style of growth, &c., in view at the same time, and I feel persuaded that they would be the principal objects of interest at such exhibitions. They are also a lady's plant, being so very neat.

I have heard an objection started to them—viz., that with their dwarfness the flowers are too small. All I would reply to such objection is, Well, take some of the largest and coarsest kinds you can find, impregnate the Pommoms, and raise a class to your own fancy. Imagine a plant 18 inches high, with a Disraeli, Geogé Glenny, or old Duke of Wellington, blooms—surely, that would be very neat and graceful. The only two growers of them that I know in the trade are Messrs. E. G. Henderson, and Messrs. J. Carter & Co., either of which firms would select a collection for any one desirous of commencing their growth much better than could be done by a mere catalogue list. Subjoined is a list of a few good ones. I would suggest that parties ordering should specify the height they

would like, as they vary from 18 inches to 40 inches; and if they are for vase, pot, or basket culture, or for small-designed flower gardens, or for front or medium edgings of flower-borders, and if they are required self-coloured or fancied, for they contain the brilliant and delicate tints of the larger kinds in miniature, were profuse in bloom and the size of a Ranunculus.

Little Elizabeth, rosy blue tipped; Little Hélène, rosy lilac, tipped purple; Little Wilhelmine, dwarf white and primrose;

Little Prince, red incurved; Little Arthur, yellow, red tip; Little Nagade, bluish white, crimson edge; Little Pet, buff; Little Julius, carmine; Honeycomb, quilled purple; Dr. Webb, orange scarlet; Annette, buff white; Crimson Beauty, crimson; Goldfinch, orange, tipped bronze; Little Beauty, red, tipped white; Little Mistress, purple self; Lady Jewel, white, striped carmine; Rosette, rosy bluish; Child of Faith, white; Gold Pheasant, yellow, tipped red; Liliput Bouquet, bluish.—NICKERBOOR.

A FEW OF OUR BEST ORCHIDS.—No. 1.

LELIA SUPERBIENS (*Gorgeous Lalia*).

Lalia was a vestal virgin, according to Roman classical authority, and was adopted as a generic name as a tribute to the beauty and delicacy of the flowers. *Superbiens*, or gorgeous, applies to the rich crimson, and yellow, and pink that are mingled in the petals, lip, and sepals.

This, as well as its kindred genus *Cattleya*, were greatly

cherished by the industry and zeal of the Royal Horticultural Society's collector, Mr. Hartweg, who gathered and sent over to the Society a great number of species, and amongst them the present. As it was forwarded in considerable quantity, it found its way into many collections. Mr. Skinner has also the merit of having introduced it very extensively.

We learn from Mr. Bateman's work on Guatemalan Orchids, that it is found growing out of the crevices of the rocks in the cooler districts of Guatemala, chiefly in places which are sheltered from the keenness of the northern winds. In such situation, the pseudo-bulbs sometimes grow 22 inches high, and have flower-scapes 4 yards long, crowned with upwards of

twenty flowers. This immense size, however, is far from being common; and when the plants are not protected on the north side, they are very small, and have an imperfect, stunted appearance. In England the flower-stems have been about 6 feet in length, and the pseudo-bulbs usually rise about a foot.

Probably the reason why flowers have not been produced

sooner, may be correctly assigned to the fact of the specimens which were first introduced having been subjected to a high temperature, with a close, moist atmosphere. These conditions being more favourable to luxuriant growth, would undoubtedly militate against the production of flowers. And it was not till the plants which have bloomed were treated in a contrary

manner, that they displayed any appearance of flower. Cattleyas and Laelias should always be grown in a lower temperature than is required by East Indian genera; and, during their winter season, water should be carefully withheld, and no moisture allowed in the house that can be prevented.—(*Partow's Magazine of Botany*.)

DENDROBIUM SPECIOSUM (*Showy Dendrobium*).

The derivation of the name of this genus is misleading. *Dendron*, a tree, and *bio*, to live, intimate that the species embraced by it are strictly epiphytal. They are not so, and the species now under consideration is an example to the contrary.

there as Port Jackson, where the night temperature is as low sometimes as 35°. When first introduced it was rarely bloomed effectively, but better information has enabled gardeners now to be more successful, and specimens were soon seen 5 feet in diameter, with nineteen or more spikes of bloom, each spike more than 2 feet long, and each comprising about one hundred

It is a native of New South Wales, and is found as far south

of its pale yellow and sweet-scented flowers. Even thirty-five spikes have been borne by one plant, but they were little more than half the length we have specified.

It is best cultivated in a greenhouse throughout the year, with temperatures such as are suited to Pelargoniums, and the following is the mode of culture adopted by the cultivator of the largest specimen we have mentioned, and published some years since by a contemporary.

The plant was grown in an intermediate-house varying from 65° to 75° in summer, but at other seasons from 45° to 55°. In May, its season of rest, it was placed in a cold pit, exposed to the sun, and very little water given. In September, the commencement of its growth season, it was returned to the intermediate-house, and freely watered.

It blooms during February and March. If grown in a stove it is luxuriant, but does not produce flowers.

BROMBOROUGH POOL WORKS

IN THE COTTAGE GARDENER, No. 629, for October 16th of last year, appeared under this title an account of some results obtained with respect to the cultivation of the Potato. The Society offers prizes for the largest and best produce of Potatoes from surfaces of ground of 6 feet square, and the results obtained by weighing the produce from several pieces offered in competition, gave the data on which the published calculations were made. The following short statement continues the account for this present year:—

The average yield of our Potatoes this year has been greater than the last two years. Thus the produce (of all kinds) has been

In 1858.....	12½ tons per acre.	In 1860.....	10½ tons per acre.
In 1859.....	10½ " " "	In 1861.....	11¼ " " "

While the proportion of small and diseased tubers though greater than in 1858 and 1859, has been much less than last year. The per-centage of good, serviceable tubers was—

In 1858.....	85½ per cent.	In 1860.....	67½ per cent.
In 1859.....	83 " " "	In 1861.....	74 " " "

The average produce of the different species grown here this season is shown in the following table:—

Kind of Potato.	Produce (total) in tons per acre.	Produce per cent. of good tubers.
Lincoln Red	13.09	78
Californian Kemp	12.56	82½
Pink Eye	12.65	47
Fluke	12.52	82½
Scotch Downs	11.43	86
Arrowsmith's Seedling	10.36	75½
Kemp (various kinds)	10.46	75½
Prussian Blue	10.15	69½

Comparing these results with those obtained in past years, we

HORTICULTURAL SOCIETY.

find that the Lincoln Red, Kemp (called here Californian), Pink Eye, Fluke, and Arrowsmith's Seedling, keep the same relative order with respect to their total produce. This is the first year that the other two species (Scotch Down and Prussian Blue) have been grown here, and it is, therefore, hardly fair to draw any conclusion as to their cropping capabilities from one year's results. Otherwise the first column of the table probably represents fairly the proportionate total produce to be expected from each species in our ground.

The results as to the per-centage of good tubers differ so widely from those previously obtained, that it would not be safe to hazard an opinion as to the characteristics of the several species in this respect. It is evident that the variations in kind and quantity of manure used, time of planting, and amount of care bestowed upon the growing crop, influence our results at present more than the tendencies of the kinds of Potato grown.

The results as to the space required for the healthy growth of the Potato plant appear to corroborate the conclusions arrived at last year. Classifying the pieces offered in competition according to the space allowed by each cultivator for one plant, and calling those in which less than 200 square inches were allowed, "small," those in which from 200 inches to 240 inches were allowed, "medium," and those in which more than 240 inches were allowed, "large," we obtain this table:—

Spaces allowed for each plant.	Average total yield in pounds from pieces of 6 feet square.	Average yield in pounds of good sound tubers.
"Small"—viz., less than 200 inches...	20.40	15.25
"Medium"—viz., 200 ins. to 240 ins....	21.17	17.22
"Large"—viz., above 240 inches.....	21.84	16.82

It appears from this table that there is no advantage in allowing a space of more than 210 square inches for each Potato plant, as the small increase of total weight obtained from the "large" space piece, appears to be due to the additional number of small immature tubers which have been formed.

It would add much to the interest and utility of these calculations, if similar results were obtained by other horticultural societies, or by holders of allotment gardens in other parts of the country. The publication of such results would do much to stimulate the holders of Potato allotments in their endeavours to secure first-rate crops, and would furnish them with information which could hardly fail to be very valuable.

The above report, furnished by Mr. Hatcher, was accompanied by a letter, from which the following are extracts:—

"I have not been able to make much of our results this year, as it is evident that we want now more systematic trials. We shall try next year to induce the allottees to plant (each one) two or three species of Potatoes and to treat them all alike. We may then get some good results as to the characters of each species of Potato—in power to resist disease—in tendency to start small tubers late in the season; and so in real productiveness, apart from the influence of variable cultivation. At present the differences due to cultivation quite overpower any differences which might exist in the several species of Potato grown.

"If the Editors could give our gardeners some information as to the best kinds of vegetables to grow, we should all feel much indebted to them. News travels slowly to us; for example, it is only this year that we have had James' Improved Carrot tried here. This species has far eclipsed all the Allingham and Orange Carrots, and will be largely grown next year without doubt. You also mentioned some new kind of Bean when here which we should be glad to try. We have all tried experiments on new species "highly recommended" by seedsmen; but it is so difficult to know what amount of dependance to place upon their statements (influenced as they must be by the quantity of seed the writer has to dispose of) that we are all quite disinclined about these trials. A list of really good new species of Peas, Beans, Carrots, Lettuce, &c., from an impartial observer would be a great boon to us; of course, some kinds very fit for high-class gardens are less adapted for cottagers where a large quantity of yield is at least as great a desideratum as beauty of form or delicacy of flavour in the produce. This may have had to do with many of our disappointments, so that we must not blame the seedmen entirely for our mishaps.

"I find that we are (in our Potato yield) above the average of this part of the country; but we might learn facts from others, both as to species to be grown, and mode of cultivation to be adopted, which would greatly improve our work.

"We have tried this year the American mode of planting Potatoes, four together in a mound and training in four opposite directions, earthing over the stems as they grow up; but this year it has failed with us—I think through too much space having been allowed. The tubers were well grown, and the proportion of good quite up to the average; but the total yield from the ground occupied was small. It was, however, only a first trial and may be improved upon next year. A solitary trial this year of the plan of laying the stem underground constantly as it grows was a great failure. There were many small tubers more than there should have been, and many diseased. In one garden two rows of Flukes were planted side by side with two rows of Pink Eyes. The latter were far more diseased than the Flukes."—W. H. HATCHER, Bromborough Pool Works, Birkenhead.

NEW BOOK.

FORMATION OF THE FLOWER GARDEN.*

The diversities of taste to which this subject has led the last few years, and the utter disregard to all conventional rules which some have fallen into in the attempt to improve their grounds, has led the Messrs. Major to publish a set of designs on geometrical flower gardening, embracing several forms of beds, and each accompanied by a concise description of the class of situation it is adapted for, and also the size of the plot of ground it will occupy. This latter information is of the greatest importance, as lamentable errors are often committed by crowding too much into a small space; but when a scale is given this can easily be avoided. The general character of the

beds in most of the figures is fanciful scroll-work, to which an imitation of foliage is occasionally attached with, however, very few acute points—one of the most difficult of all things to manage in planting; and the hub of the scroll is in no case less than 3 feet wide. Some of the designs exhibit more simple figures, and there is a very excellent way of dividing a circle into seventeen compartments worthy of general imitation. Most of the plans, of which there are twenty, are designs for figures or groups, described as suitable for plots of ground 84 yards long by 60 yards wide, down to suburban fronts of 25 yards square. In the various designs our own ideas would point out No. 5 as looking best when planted, the figures are all simple and not too much crowded. There are also two very good designs for flower gardens on gravel, but the author evidently objects to designs of this kind forming objects in front of the main windows of the residence. His observations, however, on the bedding system in general are very just, and we append the following paragraph from the preface to his book which, we believe, will be generally endorsed as being the opinion of most of our flower-garden friends.

Messrs. Major say—

"One great objection to flower gardens laid out in the grouping or bedding system being placed in front of the house, is the dreary aspect they present during the winter and early spring months. To obviate this in some degree pots of plants of the most interesting foliage, as well as hardy flowering plants, such as *Daphne azarum*, *Eschscholus multiflorus*, *Rhododendron darwinii*, *atro-virens*, *Skimmia japonica*, *Pyracantha*, *Erica carnea*, *ditto multiflora*, *ditto rigida*, ought to be kept in readiness in the reserve garden for introducing thinly into the beds at the close of the blooming season. Also patches or masses of Crocuses, Snowdrops, Hieracium, Christmas Rose, Scilla, *Lamproloma angusticaulis*, *Alone Auricula*, *Polyanthus*, *Double Primroses*, *Pulmonaria*, *Trillium grandiflorum*, *Winter Aconites*, *Early Tulips*, with other early-flowering plants of a similar kind may be introduced. These would, in a great measure, keep up the interest in the garden, and afford some degree of pleasure until the season for putting out the bedding plants came round again. These bedding plants should be strong and healthy, and ready to plant out the moment the weather will permit, so as to produce a good display, and an immediate effect. We need hardly say the beds should be thoroughly clean and fresh to receive them."

Some other useful matter is introduced into the work, all bearing on the subject of ornamental gardening. Some patterns of garden edgings of terra cotta and ironwork are also given, but they are less to our liking than the designs for beds. The work concludes with a list of bedding plants, to which we expect many of our south-country readers would be making addition as well as weeding out sundry things; but every one thinks himself entitled to give an opinion on this matter, and the list given in the work may be as good as that of any other individual list, but there are some omissions. A list of herbaceous plants is also given separately, and much useful information may be gleaned from its pages, which are not extended to inconvenient length; and the concise character of the letterpress, the good execution of the plates, and the neat manner in which the book is got up, entitle it particularly to the attention of our lady friends, to whom it is addressed.

CAPACITY OF PEACHES TO ENDURE HEAT.

In planting a small Peach-house heated by a common flue, with Royal George and Noblesse Peaches, which of these two kinds will best bear the greater heat where the flue enters, and is such the hottest part?—CLERICUS.

[The Noblesse will bear the most of the two; but you had better equalise the heat a little by making the flue thicker next the furnace for a couple of yards, or even laying sand against it and over it for a short space.]

MEYENIA ERECTA CULTURE.

WINTERING YOUNG FUCHSIAS AND SOME STOVE PLANTS.

SHOULD *Meyenia erecta* be pruned back? if so is this the proper time? A nice young plant has not yet flowered, but has made luxuriant growth this summer, and should it have a diminution of heat and moisture in the winter?

Should young Fuchsias (struck in August) potted in 60's, be kept growing now, or dried off like old plants?

Could a few hints be given respecting the winter management of the following stove plants.—*Eschscholus*, *Hibiscus rosea*, *Allamandas*, and *Dichorisandra tigrina*?—C. H. L.

[We would reduce the temperature and water, and not prune the *Meyenia* until we saw what it would do in spring, when the heat and moisture were increased.]

* *The Designer's Assistant in the Formation of the Flower Garden.* By Messrs. Major & Co., Leeds. Longman & Co., London.

The young *Fuchsias* should be kept slowly growing if it is intended to make fine plants of them next season.

Eschmannthus to flower well in spring and summer should be kept cooler and drier in winter. *Hibiscus* will be warm enough at from 15° to 55°. *Allamandas* should rarely be below 60°, except the shrub one, which is as hardy as the *Hibiscus*. We do not know *Dichorisandra tigrida*. *Thyrsiflora* is the best; it generally blooms in winter in a temperature of from 55° to 70°, requires to be pruned back in spring, grown in a moist heat in summer, and to have more sun and air in autumn.]

THE ROYAL HORTICULTURAL GARDEN AT KENSINGTON.

It is certainly fortunate for the healthy management of our public institutions that they are all liable to an unfettered criticism. This privilege, when not abused by descending into personalities or factions opposition, is not only excusable but highly recommendable, the criticised often receiving much benefit by the rebukes given them. On the other hand, it is always more pleasing to hear a good report of our doings than one of a contrary description; but censure, when merited, ought to be listened to and profited by accordingly. And the institution which forms the subject of this epistle has certainly no reason to complain if its actions do not meet the approbation of every one, since it has derived so much assistance from a source the public have been so much interested in.

The Royal Horticultural Society, with its chartered privileges and its long array of patrons, ought not to be any more exempt from public criticism than the doings of the Government; for in its capacity as a mercantile body it became bankrupt, or something very much like it, and though it has been allowed to resume business again by having received assistance from without, there is such a thing in trading affairs as a second suspension of business. Hoping, however, that this will not be the case with the newly-invigorated Society, a glance at its doings may be allowed, and its position and other features commented upon.

To those unacquainted with the new horticultural gardens at Kensington, it is proper to say that the site comprises somewhat about twenty acres of ground, slightly inclining one way, and in shape an oblong square. At one end of this is the new conservatory, a large, showy building; and along both sides are corridors, wide and spacious, the outer side being a plain wall, the garden front being a series of arches of Saracenic character; the twisted columns and enriched spandrels having more the features of that remarkable people than of the more classic works of Greece and Rome: of this, however, I leave others to give an opinion. Also over this corridor is a wide promenade, which I have no doubt, when finished, will be much used. These side corridors unite with the conservatory by a curved line towards it, and flight of steps ascend into it. The opposite end to that on which the conservatory is placed forms the entrance, and some buildings appropriated to that purpose, and others not yet complete occupy that end; but I believe the corridor and promenade are expected to be carried round the whole. This description of the outer boundary may therefore suffice by saying it is purely architectural, and is expected to be enriched by sculpture inserted in niches prepared for it, and some further embellishments, we are told, are not unlikely to be added hereafter.

Such is the boundary line of the new horticultural garden, and, as will be conceived, these corridors are seen from all parts of the grounds, being, in fact, the most imposing feature of the place. The ground itself, whatever may have been its original feature, is now carved into a number of terraces, slopes, and levels, with mathematical precision; none of these slopes, however, exceeding an elevation of 3 feet, and some of the panels are depressed about a foot or even less. A broad walk leads by the side of the corridors; and on the turf on the inner side are ornamental panels devoted to flowers and coloured materials, fully three-fourths of the space being of the latter description. The designs for this class of ornamental work are of a more simple character than that of some other panels in the centre, which are very elaborate but not suited for flowers higher than 8 inches or so. There are also four, or perhaps more compartments, composed entirely of coloured materials with lines of Box edging, small and neat, intervening between the colours. These compartments are fanciful representations of the four emblems of the four provinces comprising the British Empire—

the Rose for England, the Shamrock for Ireland, the Leek for Wales, and the Thistle for Scotland. The larger panels, comprising a mixture of flower-beds and ornamental work, have more scope for scroll work and colouring; Box-edging, however, being the boundary work for all; and certain portions of the work consist of a mass of low-kept Box to represent some portions required to be green.

Generally, I believe, all these panels are edged on the outer side joining the turf with stone kerbing. The colouring materials used seemed to be substances broken into the size of beans, and consisted of a bright red brick, and a pale yellow or stone-coloured one, blue slates, coals, a white spar or spar gravel (one of the most useful of all), and glass of two or three tints, a rich purple being the most conspicuous. Besides these simple colours different tints were formed by mixtures of two particular ones, and I think a grey stone was also used; but the above description will enable a distant reader who has no chance of seeing the garden, to understand to a certain extent its appearance. The ornamental panels being, as before stated, composed of a few flower-beds of no remarkable shapes, and only of moderate size, few, if any, exceeding 4 feet in width, and surrounded and intersected by ornamental work of the coloured material as stated above, the space occupied by the flowering plants not being more, I should say, than one-fourth, and perhaps not one-sixth of the whole panel; the remainder being what I call the embroidery, or what is called in some other places, the polychrome-beds.

In addition to the panels above alluded to, large basins or fountains intended for water are formed, or are forming, to be fed by a glut of water precipitated from an orifice in front of the conservatory. These basins are highly-finished architectural objects, and being placed in juxtaposition with each other, and at a convenient distance from the other panels, will add materially to the general effect. Broad walks with steps, where wanted, to descend a slope intersecting the whole garden, and the remainder of the ground turf with conspicuous trees or shrubs—as Irish Yews, Junipers, Yuccas, clipped Box, and the like, occupying sites allotted them on the turf. Very few beds of shrubs, and nothing planted in the natural style, so common, and yet so pleasing in other places. Everything here is done by mechanical rule, and so far as I could judge by a hasty glance at the whole, the manipulation does the workmen great credit.

In describing the garden I ought to have said that a portion of the lower end adjoining the entrance is less ornamented with panels and waterworks than the other. A maze occupying one corner, and the other partly planted with common trees may be appropriated for games or some other purpose. A terrace wall separates this portion from the rest, which will also be enriched by architectural features, which it is needless here to describe. The maze was being planted, and a wirework fence erected to make it complete at once, and to young people its tortuous windings will be, doubtless, sources of much amusement.

From the above outline of the garden it will be seen that a highly artificial enrichment pervades the whole, even the very turf itself is cut into shapes so mechanical as to become part and parcel of the whole. Slopes, levels, gentle inclines, and sharp-cut angles, rounded tops and vases, are nowhere to be found; and the whole being fresh and green, looked well in contrast with the broad walks and fanciful patterns delineated in the panelwork alluded to. Most of the trees seemed also to be doing well, and the whole reflected great credit on those having the management of the working department; but of the general effect produced by the design, as a whole, there is certainly much difference of opinion.

In the first place, may I ask it is right to call an enclosure containing only about fifty species and varieties of plants, the Royal Horticultural Garden? Even assuming there to be twice the number stated, which I really do not believe there is, do one hundred names of plants qualify a place to so high a sounding title? Assuredly foreigners must have a very imperfect notion of the extent of our horticultural matters, if they only visit the Royal Horticultural Garden at Kensington. Would not some name more indicative of the architectural and mathematical features of the place be more appropriate? I do not profess to have much knowledge of technical terms, but when the term "Royal" is used, I always expect something grand, numerous, and magnificent, and a national Horticultural Society ought certainly to cultivate more than fifty species of plants! I do not deny the fitness of the plants present for the purposes they are put to, but I certainly felt astonished at their meagre numbers.

Most cemeteries contain more; and I think some cottage gardens occupied by working men earning less than 20s. per week, could be found that contain a larger collection of plants.

I am sorry also to have to find fault with the more ornamental portion of the grounds—the polychrome or embroidery-beds. I am the more sorry to do this, as the objects intended to be represented are important ones; but though an ornamental object is in itself beautiful, when we are pleased with it, yet if that object be intended to represent anything in particular, its intention ought to be clearly seen and recognised. On the contrary, at Kensington it is difficult to distinguish the Welsh Leek from the Scotch Thistle, although they are on different panels—in fact, all attempts to imitate vegetable objects in coloured substances like those used, fall short of a child of six years old's attempts to carve the form of a man on wood. The child can imitate the head, trunk, and legs in a fashion that can be understood at a glance; but it requires more erudition than many possess to know which is Rose and which is Shamrock, and which is groundwork to both. It would be better to dispense with national emblems than mystify them in the way they are done. Not but that they may be done as well as can be done in such material, but they fall far short in effect of the great white horses cut out of the chalk hills in some places on the Great Western road. The colouring would have been equally as effective if it had merely taken forms having no definite representation. Most people admire the rich colouring and diversity of figures in the alambra at the Crystal Palace; surely something gleaned from that or some other source would have looked equally effective, and exempted critics from the unpleasantry of finding fault with what every body must think is imperfectly shown.

Of the desirability of copying such features as those brought into play at this garden into that of others of a private character there exists much difference of opinion. Most people admire it much at the first visit, and come away almost enchanted with it—their second visit is also pleasing; but repeat this many times, and the Garden is looked at with indifference—there is no change. Nature forms so unimportant a part of the picture, that she may be said to be almost set aside. Now, a thing of art ought to be exceedingly good indeed to bear repeated criticism, and yet be esteemed beautiful. A magnificent pile of building, as a cathedral, may be so, not less by its architectural beauty than by the associations it calls up; but will the fanciful work at Kensington Garden do this? and to look repeatedly on an object after all interest in it ceases is wearisome. To a certain extent this polychrome system of colouring groundwork has been carried out in several places, and heraldic and other emblems form very agreeable episodes when in conjunction with other things of a more natural description; but I do not think the plan of converting a lawn into a carpet of many colours, as done at Kensington, will receive general approbation—on the contrary, many regret its adoption there. But I by no means agree with this class; for though I would not advise its adoption to any great extent in any private place, its presence here is both excusable and (as a wide departure from the usual appearance such places possess) is very instructive, even if taken in a negative sense.

In conclusion, I disclaim all intention of acting with any discourtesy to those having the management of this great public place. The keeping of the garden, I need hardly repeat, is in excellent hands, and a place so highly artificial requires all the work attending it done to great nicety, and this is done. The turf in the middle of September was as green as it is generally met with in April, while most of similar places around London showed distressing consequences of the dry weather. The flower-beds were done to the nicety of a bouquet, and where new works were not going on everything wore the garb of neatness, indicating the assiduous care of a vigilant working staff; and, as the public are generally anxious to know how their institutions are managed, I hope some one will step forward and give his opinion how this meets their view; and whether the ideas that may be next put forth agree with those here given or not, they will be equally acceptable to the general reader, and equally so to me.—
J. RONSON.

WORK FOR THE WEEK.

KITCHEN GARDEN.

EVERY part of the garden should now be kept free from litter; Celery and all other vegetables should be trimmed at the rot-heap, and not on the quarters, as it not only looks unsightly

but harbours slugs and insects injurious to gardeners. *Broccoli*, where it has grown very vigorously, and is required late in the spring, it is advisable to dig it up, and lay it in trenches in nearly a horizontal position, covering the roots and stem up to the leaves; this has the effect of checking its luxuriant growth, and protecting the hearts of the plants in severe weather. *Lettuce*, plantations for spring use to be frequently looked over in the morning, and all slugs to be destroyed; if they should be very plentiful, sprinkle lime over the whole of the ground, either early in the morning or late at night, when the weather is mild. Secure from frost any now ready for use. *Mushrooms*, the beds now coming into bearing to be carefully looked over twice a-week; if any very dry spots are observed on the beds, slightly sprinkle them; this will scarcely be necessary if dung is used to maintain the necessary temperature. *Potatoes*, the whole of the main crop should now be got up, and carefully stowed away.

FLOWER GARDEN.

Plant Hyacinths, early Tulips, Narcissi, &c., in the open ground, and continue to pot and glass them for forcing. Plant Anemones and Ranunculuses for early blooming; but the choice kinds for showing are not put in till February. Transplant Sweet Williams, Canterbury Bells, Wallflowers, &c., into borders. Planting the different varieties of *Rees* may now be proceeded with in earnest; the ground requires to be dug to the depth of 2 feet or more, and a liberal portion of rotten dung to be mixed with the soil; when planted to be firmed tightly at the neck of each stem, and at the same time fastened to a strong stake to secure them from being loosened by the wind. A spade to be thrust under the roots of Dahlias to check their growth. Roll and cleanse lawns from worm casts; clear lime water may be employed to destroy worms if too numerous. As tree leaves are always in request, either as a fermenting material or for leaf soil, they should at this season be carefully collected. If they are required only as a manure they may be stored away in any by-place, and left to decay.

FRUIT GARDEN.

The weather is now exceedingly favourable for planting, and it should, therefore, be proceeded with expeditiously. When large trees or shrubs are to be removed, they should be taken up with the greatest care, every root should be carefully preserved, more especially the small ones; this being a matter of greater importance than that of preserving an immense ball of earth to a few of the larger roots. Should a tree lose by accident many of its roots at the time of removal a part of the head should be pruned away, as the head and root should always bear some proportion to each other. After planting they should be carefully staked, so that the wind may not have sufficient power to loosen them. Fruit trees should now be carefully pruned and trimmed, not merely those on walls, but those also which rarely have common attention—the standards in the orchard. If the heads of these were kept well thinned out, that the sun and air could reach the whole of the branches, there would be much finer fruit, much cleaner and more healthy appearance, and the ground beneath them would be less injured. It is quite improper to allow the heads of fine trees to grow into thickets of small wood instead of strong healthy shoots. One scarcely passes through an old orchard that would not be served by thinning out one-half the trees, and one-half the branches of these that are left. Look over fruit stores frequently to see that all is keeping well, and remove any fruit that may show symptoms of decay, so as to prevent the mischief from spreading.

STOVE.

During the next three months the atmospheric heat and humidity should have especial attention, for any excess in the application of either at this period of the year will prove highly detrimental to their successful cultivation by causing a premature or unseasonable growth, which no after-care can thoroughly rectify. The thermometer for the majority of stove plants need not at any time of the day exceed 60°, with a fall of 8° or 10° during the night. A selection of the winter-flowering *Begonias* will at this period form an important feature in the decoration of this structure, they being plants of easy culture may be advantageously introduced for the decoration of the conservatory or sitting-room, being previously started into bloom in the stove.

GREENHOUSE AND CONSERVATORY.

In most places *Chrysanthemums* will be the chief feature of attraction at present. They are very impatient of a close and

rather warm atmosphere; and if the house contain plants requiring such treatment, the Chrysanthemums should, as far as practicable, be placed in the coolest part where air can be given freely on every favourable opportunity. See that they are well watered at the roots, and occasionally with liquid manure.

PITS AND FRAMES.

If not already done, get straw shutters, or whatever else it may be intended to use for coverings for those prepared and put in readiness for use without delay. Expose the stock here freely to air on every favourable opportunity, so as to check growth and to get the wood firm, in which state the plants will be less liable to suffer from the confinement which may soon be necessary than if kept close and coddled with too much warmth and moisture. Very little water will be required at the root; but look over the stock every few days, withholding water until it is absolutely necessary, and then only giving a moderate soaking, which is the safest method of watering at this season. If green fly make its appearance on any of the soft-wooded plants apply tobacco smoke, that this pest may be exterminated at once, or otherwise it will disfigure and ruin them. Meaths and other plants subject to the attacks of mildew to be closely watched, and sulphur to be applied the moment the enemy is perceived. Examine Auriculas, taking off dead leaves, and above all things seeing that the plants are well dried, and have no drip from the frames. Where American and other shrubs are used for forcing, they should be taken up and potted without delay, placing them in a cold pit until they are wanted for forcing, or in a turf-pit where they can be protected from weather.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The weather being fine, gave the final earthing-up to the forward beds of *Celery*, placing ashes all round the plants to help to keep slugs from nibbling them. *Celery* will take no harm from being earthed-up now; though, if we can get hold of such a thing as a little rough stubble and leaves, we would rather use that for the last earthing-up, as, if put on lightly, it will not heat, though 6 inches or 8 inches thick, and pressed a little firm at the top and sloping to the sides, it will send the rain past the plants; and, to a great extent, when taken up as high as the top of the plants will keep frost, if not of the severest kind, out. If very severe a sprinkling of straw may just be laid on the leaves exposed. When *Celery* is grown in beds, as most of ours is, this is more necessary than when done in rows. Cleared away the leaves from Rhubarb and Sea-kale to prepare it for being taken up and forced. Have a little old hay in readiness to throw over some old lights that are now protecting a bed of Dwarf Kidneys in an earth pit if a sudden frost should come. Prepared an open piece of ground for a few Peas, though we generally prefer forward plants in spring; and commenced heching over Broccoli, and the highest greens as a security against the frost, looking after Cauliflowers, Lettuces, Endive, &c., as mentioned last week. Prepared for planting Shallots and Garlic, and weeded and thinned Onions that had to be used for salads and stand the winter, and got all roots under cover, and swept over Mushroom-beds, &c.

FRUIT GARDEN.

Planted some Oaks in a group, of good size, taking out the clay and chalk subsoil, and filled in with the good surface earth, that they may have depth as well as good surface soil to grow in, in this respect considering that forest trees should be treated quite differently from fruit trees; for, whilst in the one case the chief object is ornament and timber, in the other case fruit should be the object, and that is best promoted by comparatively shallow planting; at least, preventing if possible, the descent of tap roots into cold ungenial soil, far beyond atmospheric influence, and the power of the sun to affect the condition of the roots or the juices they absorb. In planting fruit trees, and no season can be better than just when the leaf begins to turn, this matter of entering the roots to the surface should be a special consideration. Collected a few leaves of trees, and will collect more, to throw a slight cover on the Vine-border to keep the heat of the summer from radiating away. Washed the glass, woodwork, stages, &c., of the earlyinery; pruned, washed, and tied up the Vines in bundles, to be out of the way; and filled the house with *Pelargoniums* from a cold pit, *Verbenas*, *Heliotropes*, and the

tenderest things that might be injured from damp in a cold pit. Swept off all the leaves from an early Peach-house, and syringed it well with warm water; at about 160° shutting the house up. This will soften all dirt and help to settle eggs of insects, if there are any, and will wash trees and trellis the first opportunity; and, then paint the trees with flowers of sulphur and clay. The Vines were so painted after being well washed with soap and water, as some traces of thrips appeared before the Grapes were all out. The looking after harvested fruit of hardy kinds is too much of a sinecure with us this season.

FLOWER GARDEN.

Houses much the same as last week. Took up yesterday a lot more *Geraniums*, to keep if possible as larger plants over the winter. Put them thickly, in the meantime, into our thatched Mushroom-shed, the half of which is now over, that we may take them out as we find time. Have dressed some *Mangles*, cutting off the most of the shoots and nearly all the leaves, and cramming some thirty plants into an eight-inch pot, where they will remain until March or so. Many *Scarlets* will be so treated, but more of the stems left, but all leaves removed, a little water be given to the bottom of them, dry soil placed on the surface, and the pots or boxes stowed away under stages, &c. We find an old brick pit useful for this purpose. The plants are stripped of all their leaves and the soft points of the shoots, the ends are dipped in charcoal-dust and lime, the roots are packed in soil as thick pretty well as faggots, and a little water given just to moisten the roots and the soil about them, and then in a day or two 3 inches or 4 inches of dried soil and burnt earth are thrown over that, stems and all together, and a protection from frost and air in fine weather is all they require until the middle or end of March—when breaking buds all over they must be taken out and thinned. This plan will only apply to pretty strong growing *Scarlet Geraniums*, all the variegated ones and the weaker kinds will do better under a stage, or in a loft where there is less chance of damping. Of course all young plants of this season's striking must be kept in the light and growing all the winter. Placed with a spade a little earth round *Dahlia* stems, that a sudden frost might not injure the main buds of the roots. They are still in full bloom.—R. F.

TRADE LISTS RECEIVED.

List of Plants of the Fir Tribe Suitable for the Climate of Great Britain, Cultivated by Richard Smith, at St. John's, Worcester.—A very modest title for a publication that contains more information on the subject of Conifers than many books. It is a capital catalogue and admirably got up.

A Catalogue of Pansies and other Plants Cultivated by William Dean, Bradford Nursery, Shipley, Yorkshire.—In florists' flowers generally Mr. Dean is well known as a great proficient; but in Pansies, more particularly, he holds a high place among cultivators. His is the best catalogue of Pansies we have seen.

William Clutter's List of Superb Double Hollyhocks and Pansies, Saffron Walden.—Some men grow specialties, and Mr. Clutter's seems to be Hollyhocks, of which we have before us a list of his newest and best sorts.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

DIELYTRA SPECTABILIS in WINTER (*Edith*).—To manage *Dielytra* in the open ground is only to let it alone there and let it have its own way. Ours stood last winter with hardly an inch of earth over the crown of the roots, and in April and May they were in full bloom, fine as ever, but they soon get too strong, and February is the best time to part them at the roots.

spawn, and secondly a good medium and uniform condition of the material in which they are grown in, and whether the situation be on the ground, or on a shelf, or anywhere else, so as to be in a general way may be predicted. But you will see the article by Mr. Rabson on Mushroom growing, which will perhaps meet your case.

WINTERING BEDDING PLANTS IN A VINEY. (*J. Lind.*)—You and the gardener may use the viney for the bedding plants. We fill every such place as soon as the fruit is cut and the vines have been pruned. The bedding plants will keep well at from 50° to 45° say 50° and the vines will not hurt an hour before their time if you do not go higher than that. When you begin to force, the hardest plants should be taken out—say from the second house, and the hardest there be sheltered out of doors somewhere else. Small plants, pits, houses, where Vines, Peaches, Figs, &c. are grown and the heat is used, we create with plants all winter. Fanny trees, hocks, &c. when at rest should not be above 40° with the heat, but that would be high enough for all bedding plants.

NAMES OF PLANTS. (*S. Ireland.*)—1, *Hemionitis paleolata*; 2, *Gymnogramma lutea*; 3, *Davallia pentaphylla*; 4, *Blechnum intermedium*; (*R. F. S.*)—*Toumefortia heliopedalis*, a frame plant, sometimes surviving in mild winter out of doors, in sheltered places, but not to be thus trusted.

FLOWER SHOWS FOR 1861.

NOVEMBER 6th and 7th. ROYAL HORTICULTURAL SOCIETY. (Fruit and Chrysanthemum.) *Garden Superintendent, G. Eyles.*

NOVEMBER 12th and 13th. STROKE NEWINGTON CHRYSANTHEMUM SOCIETY. *Sec., W. T. Howe.*

NOVEMBER 14th and 15th. CRYSTAL PALACE. (Chrysanthemum Show.) *Sec., W. Houghton.*

N.B.—Secretaries of Societies intending to advertise in our columns will oblige us by sending an early intimation of their exhibition days.

POULTRY, BEE, and HOUSEHOLD GERMENILE.

CRYSTAL PALACE POULTRY SHOW.

POULTRY events thicken as usual at this season of the year. We have scarcely reminded our readers that the entries for Birmingham are about to close, when we are made aware by our memoranda that it is our duty to do the same for the Crystal Palace. The Winter Show last year was such a decided success, and the influx of company so great, that it is decided again to hold it during the London Cattle Show. We do not wonder that our country friends avail themselves of the opportunity of a trip out of London to get a breath of fresh air, and that for a time they are glad to exchange the close atmosphere and more than crowded stalls of Baker Street for the luxury of elbow room and an open space at Sydenham. If we add to this the varied attractions of the place, we think we are justified in expecting that this year there will be a still larger attendance.

It has, however, fresh claims on amateur, inasmuch as Mr. Houghton, the indefatigable Secretary, has made some alterations in the prize sheet. They have been suggested to him by exhibitors, and he has at once adopted them. The first will be approved by all. It is the addition of another prize to those previously given to Game Bantams. This is such a growing class, both in numbers and popularity, that the increase was not only called for here, but will have to be adopted everywhere.

A new class is added to the Pigeon list, and there is a special sweepstake for Game Cocks. Many entries are expected in this list, as there is not one at Birmingham. We have learned to see the Crystal Palace Show as part of the winter exhibitions. The Smithfield week makes every one talk of stock. The countryman returns in December the visit the cockney paid him in August. The merits of fat beasts, the weight of swedes per acre or of a single mangold root, the experiments tried in fattening—all have their share of attention, and furnish conversation in houses where such topics are seldom heard at other times. Although the cockney speaks very guardedly when he sets the weight of a bullock, and is content to give his opinion on the merits of a sheep without handling, lest awkwardness in the operation should betray ignorance, yet when it comes to poultry many are oracles, and can discourse right learnedly on the various points and merits of the birds. Here the countrymen are at fault. It is unfortunately true that to most of them a fowl is a fowl. The cockney can also give an opinion about roots. He can see whether turnips and mangold are symmetrical. He can judge of their weight, and he can detect if holes and inequalities are artistically filled up with clay. We will, therefore, hope cocknies will support the Metropolitan Poultry Show, for such that held at the Crystal Palace must be considered. London affords no place suitable for such an exhibition, and its inhabitants should be thankful not only for the treat itself, but for the temptation it affords them of leaving the smoke for an

hour or two, of refreshing the body and improving the mind while they are indulging a hobby which shows its utility more every day.

WHO BOUGHT MY PEN OF FOWLS?

At the last Crystal Palace Show for chickens I entered a pen of Partridge Cochins, placing the price of £21 upon them, which I thought would have prevented them being claimed. They took the first prize, and, unfortunately for me, were purchased from the Secretary, who in due time informed me of the sale. I afterwards wrote to Mr. Houghton, asking to be informed who the purchaser was. He very politely answered my note, but said he had been requested to keep the name a secret. He promised, however, to write to the party, and ask permission to inform me. I have since received a second note, saying he was on no account to divulge the name of the buyer.

Since the Crystal Palace Exhibition these same birds have been shown three or four times, and entered as bred by the party now exhibiting them.

There are many reasons why this unfair practice should be disallowed; but to myself and other breeders, who have taken so much pains to improve this very beautiful and useful breed, the one great objection is the possibility of buying back under a false representation the same strain for the purpose of breeding, and, as you well know, so injuring your whole produce for at least one season.

Would you please give me your opinion as to my being able to insist upon Mr. Houghton giving up the name of the purchaser, as any other agent selling on commission any article would be obliged to do if required? I doubt not, from your disinterested position, and the opinion entertained of you by all poultry fanciers, you will be able to obtain for me the information I require in a more satisfactory manner than I have myself.—EDGAR MUSGROVE, *Liverpool.*

[The simple question is—if any one puts a price upon his pen of fowls at a poultry exhibition, and, being sold at that price, he obtains the money, has he any right to be told who bought them? We think he has not, any more than he would be entitled to demand the name of the purchaser of his cattle at a fair. He might refuse to sell unless the purchaser's name was previously imparted; but having sold and received the money he has no right to the information afterwards.]

It is quite another circumstance the purchaser exhibiting the birds as bred by himself. This is an untruth that might cause the injury Mr. Musgrove points out, and we should have no hesitation, if the case were our own, in stating publicly that the birds exhibited by Mr. A. Z. were not bred by him, but by ourselves. However, we are not aware that it is usual to state who bred the birds exhibited; and the mere fact of A. Z. exhibiting birds does not prove that he claims to have bred them.—EWS. J. OF H.]

BRONCHITIS IN FOWLS.

I SHALL thank you to inform me the best treatment for a Berking cock about eighteen months old. He has evidently been attacked with bronchitis and fever. The treatment I have given him is as follows:—On separating him from the hens which are kept in a cage yard, I bred him dosed with castor oil daily for a week, and externally rubbed his throat with spirits of turpentine, which relieved his breathing. His appetite never failed, but I reduced him from oats to boiled rice, sopped bread, and meal in water. Gave him plenty of water, occasionally putting a small piece of iron or nail into the water as he was and is still moulting. I also applied myrrh and borax to the mouth; and although the bird is better he never crows, and formerly he could be heard a quarter of a mile off, he was so fine and strong a bird.—A. M. B.

[Your treatment is quite correct so far as the castor oil is concerned. The bird would have done better without the rice. The oil must be continued as may be required, not less often than three times per week. Give twice every day stale bread steeped in strong ale, and rub the throat with strong camphor ointment. Never feed on rice.]

TWO PRIZES FOR COCHIN-CHINA CHICKENS AT THE BIRMINGHAM SHOW.—He is proposed to have separate sweepstakes, with

first and second prizes, for Buff, Partridge, and White varieties. Subscription one guinea, entries to close Nov. 20th. Further information will be given by Mr. C. Felton, Erdington.

COLLINGHAM POULTRY SHOW.

This flourishing Show came off with its usual amount of success during the past week. The poultry, although not many above 100 pens in number, included some of the best birds in the kingdom. Several of the young birds are destined to hold their own in the large shows to which they will be forwarded.

The *Dorkings* of Mr. Dobby are already known as winners at all the great shows. The Silver Grey chickens he exhibited at Collingham are extraordinary for their size and colour.

Situated in the midst of numerous Game breeders, the character of the fowls shown in that variety was, as might be expected, quite first-rate. We were much pleased with Mr. Swift's Black Reds. The Brown Red *Came Bentams* of the same exhibitor were very good; and the Single Game Bantam cock of Mr. Camm, a Black Red, was one of the smartest and most perfect birds that have been exhibited for a long time.

Mr. Dobby's Toulouse *Geese* were especially heavy, and the prize Cambridge *Turkeys* of Mr. Smith were truly magnificent.

In *Pigeons* there was a good display of over 80 pens, including many really first-rate specimens. In *Powders and Carriers*, however, the Show was poor, the best pen in each class being disqualified, from containing a deformed bird. In the *Short-faced Tumblers* there was an unusually good collection. We may especially indicate a good pair of *Yellow Balds* of Mr. Hyes, and the prize pens of Messrs. Oates and J. Percival. *Barbs* were a truly good class. Mr. Jones's second-prize pen contained the best pair of Turn-crowned we have seen, the cock being the broadest-skulled bird that ever came under our notice. The class of *Owls* included a very good pair of small whites, and a pair of imported blacks of the same character, but the presence of some white feathers in the hen prevented their being more than highly commended. The *Trumpeters* were good—Mr. Oates holding his own with his well-known whites. The *Fan-tails* were an extraordinarily good class, there being at least seven or eight pens deserving of prizes. The extra variety class was well filled, the prizes going to *Maggies*, *Priests*, *Runts*, and *Fribbels*.

The whole of the birds were on their way to their respective owners by the train leaving at eight in the evening of the day on which the Show closed.

The following is the prize list:—

SPANISH—First and Third, Lord E. Hill. Second, J. W. George, Beeston Lodge, Notts. Highly Commended, T. Wood, Boythorpe House; J. Sharp, Dorking (any colour).—First and Second, W. Dobby, Syston Old Hall. Highly Commended, J. Camm, Farnfield; Lord E. Hill, *Chickens*—First and Second, W. Dobby. Highly Commended, J. Smith, W. Spafford, Oston.

COCHIN-CHINA (Cinnamon and Buff).—First, P. W. Browne, Bull Bridge Crick. Second and Third, J. Staley.
COCHIN-CHINA (any colour).—First, W. Dobby. Second and Third, J. Staley.

GAMP (Black-breasted and other Reds).—First, R. Swift, Southwell Second, J. Staniland. Commended, J. Bradwell, Southwell; J. Wilders, near Grantham. *Chickens*—First, R. Swift. Second, G. Hylton, Swinderby, Highly Commended, J. Staniland. Commended, W. Marshall, South Collingham; H. Mantel, Collingham.

GAMP (Duckwing and other Greys and Blues).—First, R. Swift. Second, J. Bradwell, *Chickens*.—First R. Swift. Second, G. Staley.

GAMB (White and Pile).—First and Second, J. Camm. Commended, J. Wilders. *Chickens*.—First, J. Wilders. Second, J. Camm.

HAMBURG (Gold or Silver-spangled).—First, J. Key, Farnfield. Second, J. Camm. Third, T. Drabble, Winkbourne.

HAMBURG (Golden-jerelled).—First, W. Weightman, Newark. Second, S. Coley, Spring Gardens, Grantham.

HAMBURG (Silver-jerelled).—First and Second, W. Spafford, Oston.

POLAND.—Prize, Rev. S. E. Hole. Commended, Miss Staley.

BARNS-DOR FOWLS.—First and Second, W. Wright, Collingham. Third, J. Staley.

GOULD OR SILVER-LACED.—Prize, J. Bradwell.

BANTAMS (Black).—First, J. Rudwell. Second, J. Staley. Highly Commended, Rev. S. E. Hole.

BANTAMS (Gamb).—First, R. Swift. Second, R. Hawkesley. Highly Commended, J. Camm.

BANTAMS (Any other Variety).—Prize, Miss Staley.

DUCKS (White Aylesbury).—First and Second, W. Dobby.

DUCKS (Rouge).—First, Lord E. Hill. Second, R. Hawkesley, Southwell. Highly Commended, J. Bradwell.

DUCKS (Any other Variety).—First, E. J. Cooper, Collingham. Second, Lord E. Hill. Highly Commended, W. Wright, S. Sheep.

GESE.—Prize W. Dobby.

TURKEYS (Black Norfolk).—Prize, F. Houghton, West Thorpe.

TURKEYS (Any other Variety).—Prize, J. Smith.

GAME COCKS (any colour).—First, R. Swift. Second, W. H. Swann, Farnfield. Highly Commended, J. Camm.

GAME BANTAM COCKS (any colour).—First, J. Camm. Second, R. Hawkesley. Highly Commended, R. Swift; J. Camm.

PHEASANTS.—*Carriers*.—First and Second, A. L. Sylvester, 51, St. Paul's Square, Birmingham. Highly Commended, H. Child. *Pouter*.—First, H. Simpson, Newark. Second, R. H. Jones. Highly Commended, H. Gately. *Almond Tumblers*.—First and Second, A. L. Sylvester. Commended, J. Percival; H. Child. *Short-faced Mals*.—First, Mr. Oates, Pesthorpe. Second, J. W. Edge. Highly Commended, H. Yardley. *Short-faced Bantams* and *Barbs*.—First, T. Hays, A. Oates, (Hills). Second, J. Percival. Commended, W. Child; H. Jones. *Short-faced Tumblers* (Any other Variety).—First, J. Percival. Red. Second, Mr. Oates (Blacks). Commended, P. H. Jones. *Lochs*.—First and second, P. H. Jones. Highly Commended, A. L. Sylvester. *Jacobins*.—First, T. Edington, Woodmorton. Second, W. H. C. Oates. Red. Highly Commended, T. Edington. *Orls*.—First, J. Percival. Second, R. Swift. Very highly commended, Miss Donenichetti, Bosthorpe. *Trumpeters*.—First and second, W. H. C. Oates. Highly Commended, R. Swift; J. C. Tridley. *Turbits*.—First, E. A. Hargrave. Second, W. H. C. Oates. Highly Commended, J. Percival; J. C. Child. *Fan-tails*.—First, T. Edington. Second, T. Doss, Westbourne Grove, Bayswater. Highly Commended, H. Yardley. *Wans*.—First, J. C. Brierley. Second, J. W. Edge. Commended, F. Elze.

ANY OTHER VARIETY.—First, J. C. Brierley (Magpies). Second, H. Child. Third, R. Swift (Priest). Fourth, E. A. Hargrave. Commended, J. Percival (Stalings).

The Judges were Mr. Chalfour for Poultry, and Mr. Tegetmeier for Pigeons.

DISEASED SWAN.

SINCE moulting one of my Swans has become very thin. The new feathers do not grow, so that it is partially naked; it scarcely goes into the water, and there appears to be a great deal of irritation about its whole body, which it is almost constantly pecking and working with its bill. On the under side of the beak there is a swelling half the size of a walnut. It has been in this sick state a fortnight. Previously to this it kept in the orchard, and fed largely, if not entirely, on apples.—A SCRIBER.

[There is unquestionably much irritation about your Swan, and, if it continues to lose flesh, it will die. The fevered state of body prevents the healthy formation of feathers, the stubs dry up in the skin, and hence the constant pecking. All you can do is to confine the bird, and to feed on oatmeal mixed with a few whole oats. The way to induce the bird to feed is, to put a large thick sod of grass in a deep vessel, to cover it partially with gravel, to put the meal and oats on the top of this, and then to fill with water, which should be carefully poured in, and remain clear that the Swan may see the grass at the bottom.]

UNITING BEES.

I AM glad to see the subject of uniting bees, referred to in your Journal, October 22nd, page 78, by "A BARKINGSHIRE BEE-KEEPER," and I do hope he will be obliging enough to fulfil his promise by referring to the subject more fully at a future time, in hopes that there may be some more convenient and easy way made known than the fumigating and driving system which has been much tried here (north of Cheshire), during the last few years, but is now quite abandoned for the old brimstone-pit, except in my own case. I never sacrificed yet a stock in that way, but am sorry to say I have many times caused a lamentable loss of life in fumigating, which plan I have always followed with the mouse-skin hyssop and puff-ball; but with the greatest care and attention there has been scarcely a year since I began bee-keeping seventeen years ago, that I have not fumigated from two to five hives with varied success. Some have been done with scarcely any loss, but in almost every year I have had one or two overdone, and great part of the bees never recovered. Many that were fumigated and united perfectly well, were not so strong and numerous in the spring as I expected, so that I fear I have not made so much profit in bee-keeping as some of my neighbours who have made use of the abominable brimstone-pit.

I tried the driving plan six years ago, but with no success. Two years ago I determined to give it a good trial, which I did on three hives. After turning the full hive over and putting the empty one on the top, and making them fit quite even and secure where they met, I then set a man and boy to rap them, and after examining them at times, for an hour there were no signs of their going up in any quantity; therefore, I put on a bee-dress and gloves, turned up the hive—there was scarcely a handful of bees up, which were soon on the wing, then put the empty hive where the full one stood, then unscrewed the board on the top of the full one, and took the bars with the combs out, and brushed the bees off with a feather as well as I could, which returned to the

empty hive, and in the evening put them in the usual way to the stock I intended and all went well.

The other hive I did in the same way, though I must confess it was an awkward job, as there were a good number of bees lost by getting so smothered in the honey, and many could not fly for a length of time, and if the weather had changed to rain the loss would have been very great, but the day proved fine and hot, and nearly all got safe to the hive.

The following day I tried the other with the same results, and after rapping away for an hour and a quarter, and disturbing the whole neighbourhood, I was obliged to give it up and cut them out as in the other two.

I may observe, that all my hives are square bar-hives: some on the late worthy Mr. Payne's system, straw-sided and wood tops; some wood sides with flat straw tops, all the same size, so that they are quite convenient for either fumigating or driving.

I have been a regular observer of the writings on bees in your Journal since its commencement. I work principally on the depriving-system, but generally have some stocks that swarm. I have this season commenced using Mr. Tegetmeier's newly invented frame-bar hives, which I think will be very convenient for uniting, by putting the two to be united during the summer next to each other, and in the autumn put the one I wish to deprive under the one for keeping; then open part of the sides, puff a little smoke into them, and if the bees commence fighting I shall then slip a piece of perforated zinc between them, then raise the top one with a one-inch-square frame of wood the size of the boxes, cut an opening out of the frame for them to work through for two or three weeks, then remove the one-inch frame and zinc, and see if they will unite in that way.—H. Hoop, near Knutsford.

THE PROFIT OF BEE-KEEPING.

As you have copied from the *Mark Lane Express* a new edition of an old story, I now send you the original version, which is taken from the preface to the first edition of "The Bee-keeper's Guide," by the late Mr. Payne.—A DEVONSHIRE BEE-KEEPER.

A good old French Bishop in paying his annual visit to his clergy, was very much affected by the representations they made of their extreme poverty, which, indeed, the appearance of their houses and families corroborated. Whilst he was deploring the state of things which had reduced them to this sad condition, he arrived at the house of a curate, who, living amongst a poorer set of parishioners than any he had yet visited, would, he feared, be in still more woful plight than the others. Contrary, however to his expectations, he found appearances very much improved, everything about the house wore the aspect of comfort and plenty. The good Bishop was amazed. "How is this, my friend?" said he, "you are the first man that I have met with a cheerful face and a plentiful board. Have you any income independent of your cure?" "Yes, sir," said the clergyman, "I have; my family would starve on the pittance I receive from the poor people that I instruct. Come with me into the garden and I will show you the stock that yields me an excellent interest." On going to the garden he showed the Bishop a large range of bee-hives. "There is the bank," he continued, "from which I draw my annual dividend, it never stops payment." Ever after that memorable visit, when any of his clergy complained to the Bishop of poverty, he would say to them, "Keep bees! Keep bees!"

BLACK BEES AND A LIGURIAN QUEEN.

Your reply in No. 28, regarding the age of bees I cannot altogether agree with, as, if the common bees have strayed into my three Ligurian hives, they by the number now in each must have strayed by swarms, and this is not very probable, as I observe that the Ligurians will stray and remain with the common bees. I do not find they will admit or allow strangers to enter or remain with them. At the same time I do not observe that (as was said when the Ligurians were first introduced), the common bees generally kill all the Ligurians when joined to them. This last summer I joined a Ligurian queen with a few bees to a common swarm, and observed them all this season until the young ones made their appearance. Can Ligurian queens breed both common and Ligurian bees? or can a Ligurian queen after breeding Ligurian bees breed common ones? I fancy not. Would you say how I can get the bees out of

my old hive that appears to be falling to pieces? It is a common straw skep.—A. W.

[When Ligurian queens have been impregnated by black drones they frequently breed workers of both species, and this is, probably, the true explanation of the great number of black bees present in your Ligurian stocks.]

The inhabitants of the decayed straw hive had better be united to an adjoining stock by driving, as recommended in pages 45 and 46 of "Bee-keeping for the Many."]]

HOW IT FARED WITH THE PLUVIANS'

SEASON OF 1861.

Season in Renfrewshire and Ayrshire—Swarms abandoning Hives and Run-a-ways—Refractory Swarm—Bee-shooting in August.

HAPPILY FOR your correspondents, full, not laconic, replies are the order of THE JOURNAL OF HORTICULTURE; otherwise bee-keepers in this quarter would find themselves in fitting frame to answer such interrogatories as those of "A NORTH-STAFFORDSHIRE BEE-KEEPER," as to how it fared with them, curtly, never worse. This miserable season has made equally telling to our eastern neighbours the appellation "The Pluvians," launched at our unfortunate district.

Judging by the reports in your Journal, stocks at the end of last season were better found on this than the other side of the Tweed; and, generally speaking, such as had a fair population withstood all the severities of the last dreadful winter surprisingly well. We had a premature mildness early in spring, succeeded by wet blustry weather till the end of March. The months of April and May, so critical to after-prosperity, were one uninterrupted continuance of dry cutting winds, during which many stocks that had come through the trying winter perished for want of a timely supply of food from their negligent owners; and even where this was duly attended to, bee-keepers found, on the burst of splendid weather June brought with it, that breeding had been so much retarded as to throw their stocks fully three weeks behind ordinary seasons, and quite unable to avail themselves fully of an unusually rich blow of Dutch clover, then beginning to whiten our fields.

This spurt of favourable weather gave a great impetus, so that towards the end of the month stocks showed symptoms of swarming; this, again, retarded by wet weather. My first swarm came off on the 3rd of July. We had variable weather till the middle of that month, and then St. Swithen cast his watery spell over us, so that, ever since, twenty-four hours' consecutive dry weather is fairly recordable among the remarkable occurrences. The monotony of soaking moisture, relieved occasionally by torrens, even within the last two months; on four different times bringing down our little river, which peacefully meanders through what Col. Newman, on account of early-pollen gathering, fancied "some sheltered valley," a raging flood converting it into an inland lake, and bearing on its bosom crops, and even live stock, in its onward progress to the Clyde. During such a state of matters it requires no great stretch of the imagination to fancy the fix our little favourites found themselves in. An unusual deficiency of swarms (particularly second), which to all recipients have been but little gain; in many instances where feeding was neglected they have perished miserably long ago, and all round this neighbourhood I do believe there is not a single instance of a swarm that unaided would survive over the spring. Stocks not in a much better plight, except such as had a little surplus of last season's honey.

The wet stormy weather, in addition to keeping bees close prisoners at the moors, quite ruined the heather bloom, so that stocks would have been much better at home, returning in all cases lighter than they went; in many dead.

One of the leading members of the Ayrshire Apian Society, writing to me the other day, mentions, "We have had a very poor honey harvest in this locality, our hives being lighter than I ever experienced. The hive from which I obtained the third-price box was two medium swarms, and weighed only 16 lbs. in the beginning of last month, in two boxes, wrought on your adapter plan."

A peculiarity of the season noteworthy was several instances of swarms after being hived and working, some day suddenly abandoning the hive and disappearing, leaving several combs 1 inches and 5 inches deep. Run-away swarms, very common. Both being exemplifications of the sagacity of our little favourites, which, perhaps, having an intuition of the lateness, and

forebodings of the poorness of the season, flow off to take possession of the newly-made works of some defunct colony, thinking thereby to store a little honey to prolong their existence, rather than expend their energies in the fruitless task of building useless comb.

Personally we had only one refractory swarm. A large prime one on Friday, the 5th July, came off contrary to our expectation during the first burst of a thunder-storm, settled high up on an old elm overhanging the hives, and there hung with singular nonchalance during the heavy rain that made us thankful to fly to shelter, meantime getting ready the necessary paraphernalia to intercept their flight to some tenantless hive, we supposed, their high position being generally with us but the temporary anchorage from whence to shape a course to their desired haven. Mine lacking the docility of our good friend "UPWARDS AND ONWARDS" obedient boys, which after depositing themselves on some such elevation return to obtain a full and free forgiveness for their innocent lark. An hour or two afterwards, the rain having abated, found the storming party ready for the attack. After setting up a couple of ladders lashed together, a volunteer sprung up to find the unclasped, wet mossy trunk slipper than a greased pole to climb, he said, and was repulsed; the next beat off; a third seized the end of a rope, tied it round his waist together with a saw, and jumped into the ladders with a will we liked. After a hard struggle and many a slip, he wrought his way up to the lowest limb, from thence more easily upward and onward on the branch as far as it would bear his weight, sawing it, lowered it cautiously with the rope through the mass of foliage to the ground below. A few bees were by this process shaken off, but we had the bulk; so setting the hive above they soon ascended, placing it on the wall to attract the stragglers, thought the victory complete. But, alas! our hopes were groundless; for in a few minutes out they came, showing too clearly that the queen was wanting and soaring up fixed on the outmost point of one of the highest branches, far above their previous position, and quite beyond hope. A wet night setting in, not a little chagrined we beat a retreat, regretting much we had not placed a crushing finger on the royal person as we saw her coquet daintily upon the board before her flight.

Rain fell heavily all night, yet, notwithstanding, there hung the black mass, provokingly glittering in the morning sun. What was to be done? We reconnoitred their position from all points, that slim topmost branch rendering it all but impregnable. Suddenly remembering that in these days of Armstrong guns, as saucy little braves as these had come to terms, so, as a last resort, we opened fire, and by a well-directed shot snuffed through the branch, and down they came some 20 feet, giving them time to collect after their bewildering flight, again selecting as our target the branch a foot or two above the swarm, let drive—down they were once more, almost within reach this time. Mounting the garden wall we found them higher by a yard than our longest fishing-rod. Rain on again. While planning what was next to be done, they began to thin off, and shortly gathered on another topmost branch, a much diminished band, the ground being wetted with many a wetted worker; so thinking further fighting cruelty, gave in. Sabbath morning there they were—in the afternoon they were gone—with our best wishes to the lucky finder of our refractory crew.—A RENFREW-SHIRE BEE-KEEPER.

(To be continued.)

APIARIAN NOTES.

FIRST of all I have to thank "A DEVONSHIRE BEE-KEEPER" for his communication, and to declare that there was no irony meant in my communication. I certainly thought, as Hush's work was quite in an obsolete state, that my unknown friend had never seen it, as I read it nearly half a century ago.

Now, respecting the new discovery. Certainly as hen fowls, they say, have been known often to lay eggs when no male has been near them, the same might happen with insects. But "ultimately establishing the fact that a drone-breeding queen bee is a virgin queen," I presume is only meant at certain times, not always.

I beg to remind my friend that I have frequently seen two and sometimes three queens on the alighting-board of a hive, within a day, or the same day, in which a swarm has gone off, and I have had three clusters all hived from one swarm, but after placing them on the stand, have generally found the supernumerary queen, or queens, lying next day under the hive, for

I have observed that the bees never fly away with a dead queen as they do with a worker; then, again, there are many royal cells in a hive, and they are hatched at various seasons. In July, 1860, I had a small east from a stock of bees in which all the drones apparently had been killed by the bees nearly a month before (in June); this surprised me much, because I never had seen an instance of it before in my long experience.

In conclusion, I have frequently fancied that a diseased queen may, when impregnated, become quite irregular, and go out of her routine of laying; and observe the difference in the number of eggs laid in some hives to others.—H. W. NEWMAN, *Hillside, Cheltenham.*

A FORTUNE FROM A SHEEP.—In 1802, Mr. Bidwell, a law student in Stockbridge, Mass., told a poor lad that if he would catch and turn out his horse he might have it to ride home to keep Thanksgiving. The boy accepted the offer, and the day before Thanksgiving, as he was mounted on the horse ready to start for home, Mr. Bidwell handed him a silver dollar—the first dollar the boy ever had. Instead of spending it for personal gratification, as most boys now-a-days do, he bought a sheep with it. From that sheep he had, in 1832, a flock of 1061 sheep which he sold for 15 G dollars. The money he invested in up-town lots in New York city, purchasing ten lots for 250 dollars each, which he sold, in two years, for 12,000 dollars. This was the beginning of the fortune of Nathan Jackson, Esq., distinguished for his generous and munificent donations at various times to Williams' College, Mass. When a boy, the writer, with his brother and sister, each had a sheep given them, and their father kept them, and retained half the increase for keeping, thus affording an opportunity for procuring a little money which he and they could call their own. Myself, and brother, also, were allowed, each, a piece of ground to cultivate as he pleased, and were permitted to sell the products thereof for what they would fetch. In this way we were allowed to get money that we could call our own, it being the product of our own skill and industry. The brother of the writer is now a successful and forehanded farmer in Worcester county, Mass., and the writer has a farm in Hampshire county, Mass. How much these early lessons in rural industry and economy had to do with their present position can never be accurately estimated. Doubtless something and perhaps much. All farmers will find it a pleasant way thus to encourage their children by giving them an opportunity, by exercising skill and industry, to produce something they can call their own.—AN OBSERVER.—(Boston Cultivator.)

OUR LETTER BOX.

DISTINCTION BETWEEN GREY AND SILVER GREY BODINGS. (C. P.)—Grey bodings may be of any colour, inasmuch as the classes in which they are shown are for coloured bodings. A silver Grey cock should have white hackle and saddle, black breast and tail, silver and black-barred wing, no red or chestnut colour. The pullet should have a grey body, and every feather's shaft should be white, the breast pale salmon colour, and the hackle silver striped with black.

PULLED COCKLEET. (W. E. R.)—We should not allow a seven-months-old cocklet to run with more than two or three other hens.

"AN OBSERVER" ENLIGHTENED.—The observer of the mare's nest is informed, that although the present writer may very possibly possess "a still longer experience" than his critic, it has not been above asking and receiving information from a source at the head of which stands the respected name of our now venerable father, Henry Taylor, in comparison with whom he again not only modestly blinks, but frankly avows his "limited experience," and himself a young-bird-keeper.—A KENTISH-SHIRE BEE-KEEPER.

"A DEVONSHIRE BEE-KEEPER." (L. L.)—Write to T. Woodbury, Esq., Mount Ediford, Exeter.

SWELLING UNDER RABBIT'S JAW. (W. D. C.)—It is probably a gathering which will suppurate—that is, break—and then will heal; but no one can say with certainty without seeing the rabbit.

MIZZIE FOR FOWLS. (L. L. L.)—The only mizzle we know that allows the dog to open its mouth freely, yet effectually prevents the dog biting, is the French mizzle. It is a piece of iron projecting in front from beneath the mid-jaw, and strapped firmly to the head.

LONDON MARKETS.—NOVEMBER 4.

POULTRY.

We have little to note in the way of change. Still a very moderate supply, and small demand. When the weather breaks up, and people come back to town, we may look for a rise in prices.

METEOLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 48.8° and 34.4° respectively. The greatest heat, 63°, occurred on the 12th in 1841; and the lowest cold, 15°, on the 16th in 1841. During the period 125 days were fine, and on 113 rain fell.

GRAND FRUIT AND CHRYSANTHEMUM SHOW OF THE ROYAL HORTICULTURAL SOCIETY. NOVEMBER 6TH AND 7TH.

HE first visitor to the Exhibition, soon after the great conservatory was cleared of all but the Judges and those who were officially engaged, was His Royal Highness the Prince Consort; but the morning was too rough and wet for Her Majesty to venture out so early. It was also very much against the exhibitors of flowers, and many of the Chrysanthemums were roughed, and many more had to

be held back altogether, and among them the seedlings, which are described in another page, from Mr. Bird's nursery. He and Mr. Salter, in the high spirit of chivalry, did not enter the lists against common growers of this their favourite flower, but made up a match, as an additional class to the schedule of prizes, between themselves, and came out in all the strength and force of their respective systems of growing and blooming the plants.

Mr. Salter grows and blooms on the natural system out of doors, and Mr. Bird is at the very top of the tree on the classic ground of modelling his flowers on the purely artistic principle, and without "cooking" a single floret the whole season, as I, who had seen them all the previous week, can vouch for.

The Judges were, very properly, selected from the members of the Floral Committee, and their highest award went to Mr. Bird, the second to Mr. Salter. Besides the two chiefs, there were over fifty exhibitors of collections of cut blooms, and all these were put together and took up one-fourth of the space which was allotted for flowers; the one half of the back part of the conservatory being filled with them, the other half with standards and new kinds. The fruit tables occupied the middle space of the house from end to end.

The contribution plants from the friends of progress to the Society for filling this grand conservatory are increasing rapidly, and on this occasion they were disposed in an evergreen belt-like arrangement along the whole inside front of the house, and the large Chrysanthemums in pots were placed on a sloping bank of three stages behind this belt of evergreens, in one half of the house. The pot Pompons occupied the corresponding half in the same manner, and the whole made the best effect I have ever yet seen on such an occasion.

The prize list shows the degrees of merit and the receivers, and I took quite a different way of reporting the cut flowers. I never saw such an opportunity of

classifying the colours according to their shade, and I seized the opportunity to do them so for the first time. But I must mention another novelty which occurred on this occasion for the first time also—a novelty I fought hard with Dr. Laidley for five and twenty years back. At that time there was a Mrs. Randolph, the wife of a physician, who made exquisite imitation flowers out of feathers, chiefly the feathers of Brazilian birds. Mrs. Randolph exhibited collections of these till she was tired of it, but the doctor was inexorable, and would not hear of a prize, or any encouragements, no matter who battled with him.

The second novelty I allude to is this: Mrs. James Stoddard, who deceived me last year at the Crystal Palace with her artificial Dahlias, was awarded a prize for a collection of the most exquisite flowers that ever were made, and perfect models of Nature, Dahlias, Roses, Geraniums, Ranunculuses, and others of the high florist stamp. I hope I may hear that the Floral Committee will have the credit of sending the Judges who had the real good sense to encourage Mrs. Stoddard, for sure I am that half the ladies in the perrage would buy and have such beauties if once we could have them popularised at flower shows.

The third novelty was an In-door Plant Case, the invention of a lady who has devoted much care to it for some years. It is heated by hot water only, without a lamp of any kind, and we know that it preserved unharmed, even last winter, some of the choicest stove plants. On the present occasion it had grouped within it most tastefully Caladiums, Heaths, Camellias, Chinese Primroses, Begonias, Ferns, &c. It obtained great attention, was awarded a second prize, and we expect to see it become an ornament of most drawing-rooms. It is so very elegant, so very manageable, and productive of no dirt or offensive smell from the source of heat. A drawing and description will be found at page 130.

In another five and twenty years most flowers will be judged by their colours, and in their shades, as I have roughly done the Roses last summer, and now the Chrysanthemums. Out of a space of thirty-five yards long and six rows of blooms across, I began with dark purples, of which Wonderful is the very best. Very few had it there, as it is almost a new one. The rest, and all of them, are not down just as they ought to run in shading or planting, only the colours being kept together. Campestrous, Alarm, Progne, Negro Boy, Léon Lequay, and Saccia Vera, all in one class of purples.

Then, the next is *tilacy purple*, beginning with Stellaris globosa, Versailles, Delfiance (fine), Beauregarde (next finest), Aregine, Alma, and then some would set Wonderful here instead of at the head of the first section.

The next in order is *Indian red*, of which Triomphe du Nord is the head; then Prince Albert, Madame Pozzi, General Hardinge, Christopher Colomb (yellowish and Indian red), and Picturatum roseum (large).

Next is *mottled*, between buff and Indian red, beginning with Dupont de l'Eure, Pio Nono, Curtius Quintus, Arthur Wortley, Lysias, Cassy, Auguste Micé, Poudre d'Or (not Powdered Or), and next is Fabius, for which

there is not a match in the family. It stands alone between the Indian buff and the yellows.

In *Yellows*, Jardin des Plantes is far above all other yellows. This, and Wonderful, and White Queen of England, a perfectly new sport with the Messrs. Downie, Laing, & Laird, are the three best of all the new and newish Chrysanthemums. But, on with these yellows. Jardin des Plantes was in eleven collections, and every flower was first-rate in buttercup colour, and the nearest to it is Gluck, Annie Salter, Etoile Polaire, Yellow Perfection, and Plutus; but all these are a shade lighter than Jardin des Plantes. The real light yellows are—Golconda (fine), Yellow Formosa, or Lutea Formosa, Raymond next, Golconda, and Yellow Queen of England, one bloom of which in Mr. Bird's large collection was 8 inches in diameter all but a fraction. Such a flower was never seen before.

After these begin another kind of *tinted lilacs*, as Marshal Du-roc, the best of the tint, and no match to it. Then light lilacs—Thémis, Princesse Marie, Nonpareil, Beauty, Dr. McLean, Lady Harding, Alfred Salter, Glory, and Favourite.

The *blushes*, both deep and light, begin with Queen of England; Duke; Pearl; Vesta, all but white; Cassandra, ditto, and also very deep at times; Mrs. W. Holborn, a splendid bloom, all but white; Novelty, ditto, the biggest of them all.

The *pure white*, beginning with the new sport from the Queen of England, pearly white; Formosum, the purest white; Goliath, creamy white; Luridum, pearl white; White Globe, very large; and sometimes Vesta and Cassandra are pure white. One Dr. Kosas, in Mr. Bird's, is a new colour for which there was no match there—a dark rose in Chrysanthemum, colour.

Mr. Bird set up two dozen of large bouquets, each of one kind, as six bouquets of Vesta, each with eighteen blooms; two ditto Queen of England, and eighteen blooms in each; and one of Marshal Duroc, and of Fabius, Mr. Dechaups (a fine yellow), Madame Lebois, Stellaris ghosha, Thémis, two of Golden Queen of England, one of Alma and Wonderful, Gluck, Progne, Triomphe du Nord, Novelty, Dr. Kosas, and Madame Poggi. These were in cut-glass dark bottles except the three of Queen of England, and a yellow ditto, which were in silver tankards or cups won at former shows. Then he had twenty-four novelties in single blooms on a board, twelve Princesse Marie, and some Triomphe du Nord.

Mr. Salter set up as many more in similar kinds, and a full collection of Pompons in the same way, with several novelties; but I intend to see and report his whole collection in the Versailles Nursery soon. Among the collections of cut Anemone-flowered kinds, the best still was Fleur de Marie, Gluck, and Louis Bonamy; then King of Anemones and Madame Godereau, a large white kind.

Mr. Turner, of Slough, set off in the first class for pot plants six kinds, and took the Nurseryman's first prize for them. His plants were better set for effect than he ever had them, and the kinds were in three rows rising one above the other. The first row stood thus—Mount Etna first, in front above it Vesta, and above that Prince Albert; Vesta making a strong contrast with the other two. The next half, or row, began with Golden Christine, then Julie Lagrave, dark as Madame Cameron or Madame Poggi. The third, Hermione. These contrasted favourably three ways, up the row, across the rows, and cross-corner-ways.

Mr. A. Forsyth, Rectory Road, Stoke Newington, followed and took the next prize. He also set up his plants exceedingly well, thus—Golden Christine, Defiance, and Voltaire, in the first row; and Annie Salter, Mount Etna, and Vesta in the next.

Then followed the Amateurs, and Mr. Ward, gardener, to W. Fowles, Esq., Tottenham Green, took the first prize. His were the best done plants at the Show. He had Beauty du Nord (dark), Defiance, and Pilot in the first row; and General Harelock, Alma, and Golden Christine in the second. All thus as well contrasted as these from the nurseryman aforesaid. Mr. George, gardener to J. Nichol, Esq., Stamford Hill, took the second prize—thus, Vesta, Alma, and Golden Christine, first row; and Prince Albert, Insigne, and Old Christine, in the second. Now, Insigne and Christine being both of one tint, and both side by side, with the dark Prince Albert in front of them, was the very worst thing that ever was done with flowers; whereas, if Prince Albert was in the middle, the row would contrast just as Mr. Turner's first row did; but this was the only fault of setting up at the Show. A third prize was given to Mr. Glover, gardener to R. C. Lessage, Esq., Tulse Hill, Brixton, for Chevalier Damage, Mount Etna, and a very light

Christine, in the first row; and Vesta, Dr. McLean, and Golden Christine in the next, all well set for effect.

Class 3 was for three plants, and the first prize was to Mr. Ward aforesaid for Chevalier Damage, Christine, and Beauty du Nord again. The second to Mr. Harper, gardener to J. F. Bennet, Esq., Tulse Hill, for Chevalier Damage, Prince Albert, and Christine; and the third prize to Mr. George aforesaid, for Annie Salter, Christine, and Voltaire. The last two too much alike for going together.

Class 4, Pompons, six kinds again, and Mr. Turner and Mr. Forsyth were first and second in them, as in the large one. These, and indeed all the Pompons, were beautifully done. Mr. Turner's kinds were La Vogue, Mustapha, and Madame Pippin, Duruflet, Bijou de l'Horticulture, and Cedo Nulli. Mr. Forsyth's kinds were Solomon or Salomon, Le Sultan, Cedo Nulli and Yellow Cedo Nulli, Hélène and Ste. Thais.

Class 5, Same from Amateurs; and here Mr. D. Hunt, Margaret Place, Hackney Fields, took the first prize with splendid specimens of Cedo and Golden Cedo Nulli, Andromeda (the best there), Salomon, Duruflet, and Général Canrobert (the best of the yellow Pompons. Second prize to Mr. Weston, gardener to D. Martineau, Esq., Clapham Park. I took him on the wrong scent last year for bad spelling at the Crystal Palace. The collections on each side of him were set wrong, and he suffered for the wrongs of his fellows till he righted himself. He is one of the best spellers on the turf, and I am glad to book him so. His plants were excellent; Général Canrobert, Golden and plain Cedo Nulli (the three best of the family), Adonis, Hélène, and Duruflet. His Adonis was a real Adonis. Third to Mr. Ward aforesaid, for Cedo Nulli and Golden ditto, Andromeda (a fine thing), Hélène, and Duruflet. Bad luck to them; the two should never be seen in one collection of his—they are too much of a caste. Fourth prize to Mr. Bolton, Edwin Terrace, London Fields, Hackney, who had a very fine Général Canrobert, and the rest not quite so good. These were extras in this class, for they were all very good.

Class 6, Standard plants open to all comers, and Mr. Forsyth was first. Mr. Smith, Tollington Nursery, Hornsey Road:—He being a member of the Floral Committee, I took particular attention to his kinds and his way of standarding them. They were Cedo Nulli, Mr. Anstie (a capital yellow Anemone), President, Aurora Borealis, Julie Lagrave (nearly as dark as Bob), and Golden Cedo Nulli. These standards being most useful in "making up" a conservatory in the country, it was a wise resolve to give them a class and prizes, and Mr. Smith might take the lead in the trade for standards; at all events, from his way of doing them, and from his being the only one in the trade who seems to look on them as I do, I shall certainly go to him for my first standard; if ever I can get up the length of a conservatory. Mr. Salter, Mr. Bull, and others had lots of new kinds and recent ones, which I passed over, as I expected to see them under more favourable weather at the Crystal Palace, where all the novelties must take precedence of all other things.

Class 7, New varieties of this year; and Mr. Forsyth, as above, took the only prize in them, one called Rifleman being one of the best of them, and a dwarf sport from Yellow Cedo Nulli, and in the way of Comte Achille Vigier, promises to be very useful for specimens. Then he had Golden Tribly, Boadicea (large, and after the tints of Dupont de l'Eure), Golden Hermione, and Lady Harding.

Class 8, Single specimens on single stems. First prize to Mr. South, gardener to G. A. Tysler, Esq., Upton, Essex, for an immense large Christine; second to Mr. Ward; and third to Mr. Turner for more ordinary-grown plants. D. BEATON.

FRUIT.

This exhibition of Fruit far surpassed any other that the Society has ever held. Whether it is that it was displayed to better advantage in the large conservatory at Kensington Gore than at either Willis's or St. James's Rooms, or whether it was greater in extent and altogether finer, certain it is that it was far more effective and attractive than either of those. The collections were arranged on a long table extending the whole length of the conservatory, separated in the centre by a transverse table, in the centre of which was a splendid specimen of a Tangerine Orange tree, and round it were arranged the "collections" of fruits. On this table some of the most extraordinary specimens of fruits were exhibited. Twelve Uvedale's St. Germain's, exhibited by Mr. Solomon, weighed upwards of 39 lbs, Bauré Diel 2 lbs. each, and Catillac 2 lbs. each. The other attractive

exhibitions were the Grapes of Mr. Henderson, of Trentham; Mr. Hill, of Keele Hall; Mr. Tillyard, of Stanmore Priory; Mr. Kay, of Finchley; and Mr. Meredith, of Garston.

The Pears from Mr. Anderson, of Oxenford Castle, N.B., and those of Mr. Ingram, of Frogmore, Mr. Dwerrihouse, of Heckfield, and Mr. Harrison, of Outlands, attracted particular attention. While the Apples of Mr. Newton, of Enfield, Mr. Ingram, of Frogmore, and Mr. Sidney Ford, of Horsham, were the most attractive in their class. It is impossible, in such a collection to specify any except those that were the most prominent, and we must, therefore, confine our report, with a few exceptions, to those only which gained the awards.

Class A, COLLECTION OF FRUITES (Fruiterers only).—In Mr. Solomon's collection there were baskets of some of the largest Pears that ever were exhibited. They were all of foreign growth, and included Uvedale's St. Germain under the name of Belle Angévine, Vicar of Winkfield called Ben Curé, Beurré Diel, Mâster Beurré, Catillac, St. Germain, Winter Bonchrétien under the name of Bonchrétien d'Auch, Crasanne, Glon Moreau, and a variety of brilliant colour called Cuisse Madame, but which was Spanish Bonchrétien. The Apples were Reinettes de Canada, Calville blanche, and Pomme d'Api. There was also a basket of Black Hamburg and Muscat of Alexandria, along with two boxes of Chasselas de Fontainebleau Grapes, beautifully russeted. These, with four Melons, four Pines, a basket of Oranges, one of Pomegranates, and one of Peaches, made up a magnificent collection of forty-nine dishes. This, of course, received the first prize. The second prize was awarded to Messrs. Webber & Co., of Covent Garden. This, too, was a very fine collection, and consisted mainly of English-grown fruit. This collection was served up in the beautiful white-glazed china ornaments of Messrs. Minton, which produced a highly ornamental group.

Class B, FOR COLLECTION OF FRUITS FOR PRIVATE GROWERS.—In this class there were three competitors—Mr. Henderson, of Trentham, and Mr. Tillyard, of Stanmore, being equal firsts; and Mr. Kalle, of East Horsley Towers, Surrey, being third. In Mr. Henderson's collection there were twenty-eight subjects exhibited, of which his White Muscats, Black Hamburg, and Lady Downe's Seeding Grapes were very excellent. There were three Melons—Cashmere, Cocoa-nut, and Gem; King of the Pippins, Blenheim Pippin and Calville blanche Apples; and in Pears Easter Beurré, Knight's Monach, Forelle, Duchesse d'Angoulême (exhibited as Beurré Vert), Brown Bance, Beurré Diel, Beurré Clairgeau, Winter Nelis, Beurré Rancé, Bergamotte d'Espérance, Jersey Gratiaoli, all good, with the exception of Forelle and Beurré Clairgeau, which were deficient in colour. A dish of White Ischia Figs, one of a green Plum (erroneously called Coe's Late), and Eugenia Ugni, made up the collection. In Mr. Tillyard's the Grapes were very fine, and consisted of Muscat of Alexandria in fine condition, and of a fine amber colour; White Tokay large bunches; immense bunches of Trebbiano; and a basket of Oldaker's St. Peter's. He had four towering Lemon Queen Pines, and two of the Old Queen. The Pears were Napoléon, Glon Moreau, two dishes of Beurré de Capiaumont, Beurré d'Arenberg, Chaumontel, and Passe Colmat. The Apples were Alfriston, Blenheim Pippin, Margil, Downton Pippin, Fearn's Pippin, an Apple called Wellington, but which was more like Wormsley Pippin, and in all probability was so; and Lamb Abbey Pearmain. His Plums were fine, and were Coe's Late Red, and two dishes of Blue Impératrice. The two Melons were Heckfield Scarlet Flesh and Hybrid Cashmere. There was a basket of fine Morello Cherries, a dish of Angehque Figs, two dishes of Raspberries, one of White Currants, and one of Eugenia Ugni—in all thirty-three subjects. Mr. Kalle's exhibition was a small one, and consisted of only twelve subjects, all of which were good of their kind. There were four dishes of Apples, two of which were Fearn's Pippin, one Golden Winter Pearmain, and one Herefordshire Pearmain. One small Pine, one Melon, one dish of Marie Louise Pear, one dish of Black Hamburg Grapes, one of Coe's Golden Drop, and one of Coe's Late Red Plum, one dish of Medlars, and one of Raspberries.

In Class C, PINE APPLES (three distinct kinds), there were three exhibitions. The first prize was awarded to Mr. Page, gardener to W. Leaf, Esq., Streatham, for Queen, Smooth-leaved Cayenne, and Ripley Queen. Second to Mr. Muggleton, gardener to Alderman Cubitt, Penton Lodge, Andover, for Smooth-leaved Cayenne, Prickly Cayenne, and Queen. Third to Mr. Botger, gardener to J. Gott, Esq., Aramley House, Leeds, for Montserrat and two Euville.

In Class D, FOR A SINGLE FRUIT OF ANY VARIETY OF PINE APPLE, there were thirty-three exhibitors. The first prize was awarded to Mr. J. Flood, gardener to R. Fothergill, Esq., Aberaman House, Aberdare, Glamorganshire, for a very fine Smooth-leaved Cayenne, weighing 7 lbs. 11 ozs.; the second to Mr. Thomas Ingram, gardener to Her Majesty at Frogmore, for a very large and handsome Queen; and the third to Mr. Tillyard, gardener to J. Kelk, Esq., the Priory, Stanmore, for a fine tall Lemon Queen.

In Class E, FOR BASKETS OF MUSCATS of not less than 10 lbs., the exhibitions were very fine, and particularly those of Mr. Tillyard, of the Priory, Stanmore, to which the first prize was awarded. The bunches were large and finely set; the berries were also large, full, and plump, and of a beautiful amber colour, and the aggregate weight was 22½ lbs. Those of Mr. Hill, of Keele Hall, to which the second prize was awarded, were not quite so large as Mr. Tillyard's, and were more highly ripened, having begun to shrivel; but they were of a very fine amber colour. The third prize was awarded to Mr. Joseph Meredith, of Garston, near Liverpool. They were finely coloured, but not as large as either Mr. Hill's or Mr. Tillyard's, but they were well ripened and of very rich flavour. Those of Mr. Kay, market gardener, Finchley, were well grown, plump, and well set, but not so highly ripened as either of the preceding, and they were rather green.

Class F, WHITE MUSCATS, single dish. In this class there were some very good exhibitions. Mr. Tillyard was first with three short, broad, thickly-set bunches of very large, roundish-oval berries, of a fine amber colour. Mr. Hill was second; his three bunches were long and tapering, well set, and beautifully coloured; one of them, which was the largest, was a very handsome bunch; but the other two were rather smaller. The exhibition of Mr. Meads, of Manly, Blackwater, Hants, consisted of three splendid bunches; but, unfortunately, every berry was marked with a dark brown spot on the end, which quite spoiled their appearance. It is worth recording that the Vines which produced these fruit had only been planted sixteen months. The variety exhibited by Mr. Tillery, of Welbeck, appears to be distinct from all the others. The bunch is very long, tapering, and loose, and the berries, which are of a darker colour, are also much longer and more oval than any of the others. Those exhibited by Robert Crawshaw, Esq., of Cyfartha Castle, Merthyr Tydvil, seemed to be the same variety as Mr. Tillery's; but they were not so well coloured, being altogether of a greenish colour.

In Class G, which consisted of a single dish of WHITE GRAPES OF ANY VARIETY, Mr. Hill was first with three enormous bunches of Trebbiano, the largest we every saw of that variety, the weight of the aggregate being 9½ lbs. The berries were very large, and of a fine pearly colour. The second prize was awarded to Mr. Meredith for three bunches of White Nice, the aggregate weight of which was 9 lbs. 12 ozs. The third prize was taken by Mr. Tillery, of Welbeck, with Trebbiano, three very excellent bunches. Among the White Grapes was shown a collection of four sorts of Muscats sent by Mr. David Thomson, of Archedfield; they consisted of Muscat of Alexandria, a short, thick-set bunch; the Tynningham Muscat, a long, tapering bunch, like those that Mr. Tillery showed; the Bowood Muscat, a short, thick-set bunch, like Muscat of Alexandria, but much more advanced in ripeness; and a form of Muscat, which was so far ripened as to have almost become raisins. These were all grown in the same house under the same circumstances, and were sent to exhibit the different forms the varieties present. Upon these the Fruit Committee will report at their next meeting.

Class II, BLACK HAMBURG GRAPES (in baskets of not less than 10 lbs.) The first prize was taken by Mr. Kay, market gardener, Finchley; the berries were large and finely bloomed. Mr. Hill, who was second, had also a very fine basket, and very little, if at all, inferior to those exhibited by Mr. Kay; but, in consequence of having been necessarily so long out, and having to travel so great a distance, they had not the freshness of those which took the first prize. The third prize was awarded to Mr. Henderson of Trentham, whose Grapes were not so large as Mr. Kay's and Mr. Hill's, but were nevertheless of excellent quality.

Class I, BRACK HAMBURG GRAPES (single dish). The first prize in this class was awarded to Mr. Henderson, of Trentham, for three beautiful bunches, short, broad, and thickly set; the colour was of a jet black, and not a berry was rubbed. Mr. Kay was second and Mr. Hill third.

The only exhibitor in Class J was Mr. Henderson, of Trentham, whose Frankenthals were true; and it is to be re-

marked that every Black Hamburgh which was exhibited at the Show were Frankentals.

Class K, BLACK GRAPES (any variety). The first prize in this class was awarded to Mr. Page, gardener to W. Leaf, Esq., Stratford, for Barbarossa, small short bunches for that variety, but the berries were large, finely coloured, and closely set. The second prize was awarded to Mr. Hill, of Keele Hall, for Lady Dowse's Seedling and Trencham Black, both very good.

Class L.—This class, which was for collections of PEARS (one dish of each) was well represented both in quantity and quality. The most remarkable point in this exhibition is, that the first prize was awarded to a collection grown so far north as the neighbourhood of Edinburgh. It was sent by Mr. Anderson, gardener to the Earl of Stair, Oxenford Castle, and containing no less than twenty-two distinct sorts. They were—Marie Louise, Duchesse d'Angoulême, Louise Bourne of Jersey, Papillon, Crasme, Beurré Diel, Beurré d'Arnhem, Beurré de Chaumont, Peurré Clairéau, Easter Beurré, Winter Nelis, Glou Moreau, King Edward, Colmar d'Arnhem, Doyenné Gris, Buchanan's Spring Beurré, Colmar, Flemish Beauty, Poire Neill, Marché de la Cour, Suzette de Bayar, and Rousse Lench. They were all good specimens, though from being grown so far north they had not attained the same degree of maturity as the generality of the other collections; but there was not an inferior dish, nor one incorrectly named, among them. The second prize was awarded to Mr. Ingram, gardener to Her Majesty at Frogmore. This was a smaller collection than the preceding, but the fruit was large, very fine, and just ready for table. It consisted of Chaumont, Van Mons Léon le Clerc, Vicar of Winkfield, Knight's Monarch, Marie Louise, Easter Beurré, Prince Albert, Jasse Colmar, Fladberg, Beurré Diel, Glou Moreau, Beurré de Rance, and Meece. Mr. Durrhoush, gardener to Lord Eversley, at Heckfield, took the third prize with a very excellent collection, consisting of Marie Louise, Josephine de Malines, Triomphe de Jodoigne, Winter Nelis, Beurré Diel, Delices d'Hardenpont, Easter Beurré, Swan's Egg, Napoleon, Duchesse d'Angoulême, St. Michel, Beurré de Rance, Passe Colmar, and Knight's Monarch. The collection exhibited by Mr. Cox, of Redleaf, in this class, was also meritorious, and contained some good specimens.

Class M, DESSERT PEARS (in six distinct kinds). In this Mr. Ingram, of Frogmore, was first with beautiful glowing specimens of Van Mons Léon le Clerc, Beurré Diel, Glou Moreau, Beurré de Rance, and Knight's Monarch; the last grown as nobody else ever grows it, with a fine bronzy glow on one side of it. The second prize was awarded to Mr. Harrison, of Oatlands, for Marie Louise, Passe Colmar, Glou Moreau, Ne Plus Meuris, and Winter Nelis; and the third, to Mr. Spivey, gardener to A. Houlton, Esq., Hallingbury, Bishop Stortford, for Josephine de Malines, Passe Colmar, Beurré Diel, Glou Moreau, Marie Louise, and Thompson's.

Class N, DESSERT PEARS (three dishes of distinct kinds). In this class there were some fine dishes, particularly those of Mr. Harrison, of Oatlands, which were tastefully set up and surrounded with coloured tissue papers. They were—Marie Louise, Duchesse d'Angoulême, and Glou Moreau. The second prize was awarded to Mr. G. Tranter, gardener to the Hon. G. D. Ryder, Westbrock, Hemel Hempstead, for Brown Beurré, Marie Louise, and Beurré Diel; and the third, to Mr. S. Ralphs, gardener to R. Sturges, Esq., Mount Felix, Walton-on-Thames.

Class O, DESSERT PEARS (single dish). In this there were a great many entries, but generally speaking very few of the exhibitions were anything remarkable considering the great number that was exhibited. The first prize was awarded to Mr. Ingram, of Frogmore, for very fine specimens of Glou Moreau; second to Mr. Tranter, for Marie Louise; and third to Mr. S. Ralphs, for Beurré Diel. An extra prize in this class was awarded to Mr. F. Westbrock, Abingdon, Berks, for a dish of Beurré d'Arnhem.

Class P.—In this class, which was for UVEDALE'S ST. GERMAIN PEARS, Mr. Snow, gardener to the Comtesse Cowper, West Park, was first; Mr. Park, gardener to G. H. Vernon, Esq., Retford, second; and Mr. R. W. Creak, gardener to F. F. Rufford, Esq., Stourbridge, was third.

Class Q, was for CATLENE PEARS, and the first prize was taken by Mr. Harrison, of Oatlands; the second by Mr. D. Cunningham, gardener to the Bishop of London, Fulham; and the third by Mr. W. John Barnett, Decker Hill, Shifford.

Class R, for KITCHEN PEARS of any variety. Mr. Snow was first with Warden; Mr. Barnett, for Beurré Diel; and no third was awarded. In this class Mr. Cunningham exhibited very

good specimens of Catillae, but as there was a special class for them they could not compete. We do not quite see the propriety of admitting Beurré Diel into this class as a Kitchen Pear, if so, then any Pear which is not ripe may be regarded as a kitchen Pear. There ought to be a line drawn somewhere, or it ought to be defined what is a kitchen Pear.

In class S, for the HEAVIEST FIVE DESSERT PEARS, the first prize was awarded to Mr. Tranter; the second to Mr. Spivey; and the third to Mr. Durrhoush.

Class T, for STRAWED PEARS. This class was well represented, and closely contested. It was a condition this year that the fruit should be prepared without sugar, spice, or any colouring matter, the real object of the exhibition being to ascertain which was the best sort for stewing, and which had in itself most sugar and flavour. At the former exhibitions, extraneous substances were used, such as sugar, spice, and colouring matter, so that the true character of the fruit was completely disguised, and the artist who most skilfully manipulated with these accessories and prepared the most palatable dish was proclaimed the successful candidate. On this occasion the fruit was perfectly natural, and the Swan's Egg prepared by Miss Ingram, of Frogmore, received the first prize; Miss Ingram also exhibited a Vicar of Winkfield, which were second in quality. But as an exhibitor cannot take two prizes in the same class, the second prize was awarded to Mrs. Powell, Cedars Cottage, Old Windsor, for Chaumont; and the third prize to Mrs. Smith, Upper Sydenham, for Chaumont. There were also several other exhibitions; but there were none that were at all good in flavour, and some were positively flavourless. Miss Ingram also exhibited a jar of baked and dried Swan's Egg, which were very good.

Class U, collection of DESSERT APPLES (one dish of each). In this class there were some very fine exhibitions. The fruit was well grown, and very finely coloured. The first prize was awarded to Mr. John Newton, gardener to G. J. Graham, Esq., East Lodge, Finchley Chase, who exhibited Ribston Pippin, Cackle Pippin, Pearson's Plate, Cornish Gildflower, Fearn's Pippin, Golden Reinette, Margil, Hicks' Fancy, Bechauswell, Court of Wick, Old Golden Pippin, Downton Nonpareil, King of the Pippins, Franklin's Golden Pippin, Green Nonpareil, Herefordshire Pearmain, Golden Nonpareil, Golden Russet, De Neige, Adams' Pearmain, Sam Young, Screevton Golden Pippin, and Cluster Golden Pippin. The second prize was awarded to Mr. Cox, of Redleaf, for Fearn's Pippin, Castle Major, Court of Wick, Golden Knob, Col. Vaughan, Brabant Bellefleur, Court Pendu Plat, General Wolfe, Golden Winter Pearmain, Franklin's Golden Pippin, Cracking Pearmain, Ribston, Farleigh Pippin, Hughes' Golden Pippin, Winter Queening, Maid of Taunton, Kirke's Golden Reinette, various Nonpareils, Scarlet Pearmain, Royal Russet, Lemon Pippin, Downton, Hollow-eyed Pippin, and Christie's Pippin. The third prize was awarded to Mr. Mortimore, gardener to the late Miss Brown, Carsholton, for Ribston, Prince's Pippins, Yellow Ingestre, Franklin's Golden Pippin, Bull's Golden Reinette, Newtown Pippin, Claygate Pearmain, Wormsley Pippin, Blenheim Orange, and King of the Pippins.

Class V, DESSERT APPLES, collection of six dishes distinct sorts. The first prize was awarded to Mr. Ingram, gardener to Her Majesty at Frogmore, for Rosemary Russet, Small's Golden Pippin, Cox's Orange Pippin, Fearn's Pippin, Old Nonpareil, and Court Pendu Plat. The second prize was awarded to Mr. Snow for Cornish Brambling, and Fearn's Pippin; Court Pendu Plat, Ribston, and Bull's Golden Reinette. Mr. Newton was third with Cornish Gildflower, Fearn's Pippin, Pearson's Plate, Ribston, Cackle Pippin, and King of the Pippins.

Class W, DESSERT APPLES (three dishes). The first prize was awarded to Mr. Sidney Ford, gardener to W. E. Hubbard, Esq., Horsham. They consisted of Ribston Pippin, Blenheim Pippin, and King of the Pippins. The second was awarded to Mr. Rutland, Garstone Castle, Hereford, for Fearn's Pippin, Ribston, and King of the Pippins. Mr. W. Hall, gardener to Capt. F. Fordhook, of Ealing, third for Court Pendu Plat, Ribston Pippin, and King of the Pippins.

Class X, DESSERT APPLES (single dish). In this class the exhibitions were very numerous, and contained a vast number of varieties, many of which were not usually met with at fruit exhibitions, and were evidently sorts of local interest. The first prize was awarded to Mr. Ingram, of Frogmore, for Cox's Orange Pippin; and Mr. Simpson, gardener to Lady Molyneux, Stoke Farm, Slough, was second; Mr. Turner, of Slough, being third, both with Cox's Orange Pippin. All the exhibitions of

this beautiful Apple were remarkably fine. This colour was bright, and the flavour very fine.

Class V, COLLECTION OF KITCHEN APPLES (one dish of each). The first prize was awarded to Mr. Mortimer, Carshalton, for Celine, Golden Noble, Beauty of Wilts, Robson Pippin, Hawthorned, Blenheim Orange, Hoary Morning, Kirke's Admirable, Worsley Pippin, and Dumelow's Seedling. Mr. Newton, gardener to G. J. Graham, Esq., was second with Holland Pippin, Beauty of Kent, Brabant Bellefleur, Norfolk Beefing, and Kentish Filbasket.

Class Z, SIX DISHES OF KITCHEN APPLES. Mr. Betteridge, Steventon, Berks, was first with Alfriston, Kentish Codlin, Minehall Crab, Cat's Head, and Blenheim Orange. Mr. Snow was second with Wellington, Blenheim Orange, Camberlain, Golden Noble, Celine, and Bedfordshire Foundling.

Class AA, Three dishes of KITCHEN APPLES. Mr. Smith, gardener, Liscard, Cheshire, was first with Mère de Ménage, Alfriston, and Beauty of Kent. Mr. Holler, of Eton, was second with Celine, Blenheim Pippin, and Alfriston.

Class BB, Single dishes of KITCHEN APPLES. The first prize was awarded to Mr. Lee, gardener to Viscount Combermere, Whitechurch, Salop, for Mère de Ménage (immense fruit); second to Mr. Young, gardener to R. Barclay, Esq., Highgate, for Alfriston.

Class CC, KITCHEN APPLES, the heaviest fire fruit. The first prize was awarded to Mr. Green, gardener to Mrs. Honeywood, Kelvedon, Essex, for Gloria Mundi, called American Pippin, weight in the aggregate 5 lbs. 5 ozs.

Class DD, POMMES TAPÉES.—This is the name given to Apples dried in the way of Normandy Pippins. There was only one exhibition, and the first prize was awarded to Mr. William Young, gardener to R. Barclay, Esq., West Hill House, Highgate. The sort upon which the experiment was made was Blenheim Pippin, and the attempt was to some extent successful, but they were not so dry as Normandy Pippins are, nor would they keep so well.

Class EE, ORANGES, LEMONS, &c., one dish of each. There was only one collection exhibited, for which the first prize was awarded to Mr. W. Latoman, gardener to J. Campbell, Esq., Hendon.

Class FF and GG, ORANGES in Pots, there was no competition. **Class III, MELONS.**—In this class there was a very good exhibition for the season, but few of them were of any worth. The Heckford Hybrid exhibited by Mr. Duerriehouse, and to which the first prize was awarded, was a most delicious fruit, and quite equal to any Melon in the best of the season. Mr. Fryer, gardener to G. Perkins, Esq., Sevenoaks, was second with a very good green-fleshed Melon; and Mr. J. Barnst, Decker Hill, Shiffnal, was third.

Class II, PLUMS (single dish).—The first prize was awarded to Mr. Snow for some very excellent Blue Impératrice, which were plump and richly flavoured. Mr. Cox, of Redleaf, and Mr. Mortimer, of Carshalton respectively took the second and third prizes for the same variety, which were more shrivelled than Mr. Snow's. Some very good-looking Reine Claude de Barvy were exhibited, but they were quite wanting in flavour.

In Class JJ there was a splendid dish of Sir Harry Strawberry, exhibited by Mr. J. Widdowson, gardener to G. Barnes, Esq., Chorleywood, Herts, to whom the prize was awarded.

In Class KK, CURRANTS, there was no competition. **Class LL, RASPBERRIES (single dish).**—There were two exhibitions, one by Mr. F. W. Park, who received the first prize, and one by Mr. W. Kaile, East Horsley Towers, who received the second prize. In both cases the fruit was small, and quite without flavour.

Class MM, MISCELLANEOUS.—Mr. Hill, of Keele Hall, sent a very interesting collection of Grapes of thirteen varieties. They included—Black Hamburg, Muscat of Alexandria, Treuthian Black, Lady Downe's Seedling, Muscat Hauburg, Black Prince, Marchioness of Hastings, West's St. Peter's, Sahibee, Bidwell's Seedling, Old Tokay, Barbarossa, and a splendid little Grape, called Muscat Noir d'Angers, deliciously flavoured, and with a fine Muscat aroma. To this the first prize was awarded. Mr. Ivory exhibited large roots of Dioscorea batatas. A bag of a new seedling Potato, raised by Mr. S. A. Daintree, of Fen Drayton, near St. Ives, Hunts, was exhibited, which is reported to be ten days to a fortnight earlier than Ashleaved Kidney, and to keep in good eating condition till the new Potatoes come again. Mr. Ingram, of Frogmore, sent a fine dish of Salway Peaches, to which a fifth prize was awarded. There were several other exhibitions in this class, but for which we have not space to record.

CHRYSANTHEMUMS AND OTHER FLOWERS

AT MR. BIRD'S, GREEN LANES, STORE NEWINGTON,

OCTOBER 31.

WHEN Mr. Bird took the lead in Chrysanthemums, those whom he distanced and kept at their proper distance at the shows congratulated themselves with the comfortable idea, or rather with the discovery which a learned friend of mine had made, and by which he could account for the success of this spirited grower—namely, that the whole secret of his success was owing to Mr. Bird's nursery being bounded by the old Hackney brook, which was richer than any mixture that could be made with any or all the fertilisers put together. And as it is pleasant to find that we are much of the same mind as our best friends, I must just say, in justice to the friend I alluded to, that I was much of the same mind with him on that point. But, in justice to Mr. Bird, also, I must now confess that my friend and myself were just as wide of the mark as if we could not hit the Monument.

There is no Hackney brook along that way now. The high-level-drainage people swallowed the brook, and put in two thousand cubic yards, or loads, of their excavation, to fill up the channel of the fertile waters by which they and we, the beaten and their comforters, supposed Mr. Bird's success had originated. All this season Mr. Bird was under the necessity of using clean, clear water from the New River Company for all his plants. He had to go to a large expense, and did so, just as he does his Chrysanthemums. He has the river water on in every house, and a tap in the centre of each division of his houses, with a long coil of gutta percha pipe to each tap, by which, instead of with watering-pots, he waters all his plants, and the same arrangement is all over the place. But the plan pays, and that is enough; no matter what a thing costs, if you can afford it, as long as it will pay to do it according to Mr. Bird's way of doing business.

Well, he does business all over the three kingdoms, and to America and Australia, in a most extraordinary manner for an Englishman. He keeps no books, I mean account-books. He is a ready-money merchant, and if we cannot do business with him that way, why we cannot see the way he packs his plants for long journeys in general, and for short ones in particular.

The way I pack my Geraniums for my agents is different, as I thought, from the packing of all the nurserymen in the world. The Messrs. Henderson, of the Wellington Road Nursery, have never seen my way of packing among all their trade dealings. I have sent plants of Geraniums to all parts of Europe, and to the southern States of America, by way of New York, as safe as any one who ever tried. But now I have just seen and learned that Mr. Bird packs his Chrysanthemums exactly as I have done Geraniums for the last five and twenty years, and quite different from all other nurserymen. It is for the cheapest and safest way for bedding stuff and all common plants.

The balls are turned out of pot, and wrapped in a square of newspaper. The top of the plant is just within the folds of the paper, and that end is left loose; the bottom is done by doubling over the folds of paper round the ball, and by that way of doing it one thousand plants can be put into one case, all in paper parcels open at one end. If any one of them gets a damp leaf, or anything the matter with it, that indisposition is confined to the one plant, or one parcel.

Well, without a drop of liquid manure from first to last, Mr. Bird has far better flowers this season than ever he had before; and I should think no one about town or from the country will have a chance against him, so that my notes can very soon be verified or be put to the test. Of Vesta alone he could cut a thousand blooms the last week of October, and I should think he might cut from five hundred to a thousand blooms every week during the whole season, and such blooms as few, if any, can come up to.

Mr. Beck, at the west corner of Covent Garden, sells all these flowers and all other flowers which Mr. Bird cuts, which would tingle the ears of country people if I were to mention the tenth part of them.

What would you say to forcing fifty thousand Hyacinths in two months' time, as many Tulips, and ten times more of other bulbs and roots? But I would be afraid of saying how many thousands I had seen there in preparation—there are whole fields of frames and pits full of them; but I made sure of his system, which is different to ours.

All his Tulips and Crocuses are under glass in cold quarters to save them from mice. These bring the only two kinds which

they take to, the Hyacinths, Narcissi, and the Lilies, the mice do not touch; therefore, they are placed in beds out in the open yard. The pots are set on the bare bottom, and then a thick covering of spent hops is placed all over the beds. By Christmas the leaves and flower-buds are just out from the bulbs, and the pots are full of roots, then they are ready for forcing. They are taken to stove heat, and set again in the dark along the sides of the flues and hot-water pipes, and a thick layer of spent hops is set over them again, and left on them till the leaves and flower-stems are 5 inches or 6 inches long, and blanched white as the heart of Celery, the heat being from 60° to 80°. Then they are taken out of the hops and set on the stages, and are syringed to clean the remains of the mulching from them. At this stage the heat is kept up to 80° for a few days, and Mr. Bird assured me that in three days in that heat the Hyacinth leaves and flower-stems get as green as grass, and very soon run up amazingly; then the heat is lowered, and they are soon in bloom, and that is exactly how the best and earliest Hyacinths in Covent Garden are raised.

Then of Cyclamens, one would think he, Mr. Bird, has enough for the three kingdoms himself of all sorts and sizes, and his last seedlings in 100 broad pans, and 100 to 150 in a pan, are from seeds ten years old. Mr. Bird says that Balsam seeds and Cyclamen seeds keep good enough for twenty years.

Before I leave them, I may state that the true *Cyclamen verum* is seeding in my own garden just now. The plant I had was in a bad state when I had it, and I was told it had been so for three years before I had it. This kind makes a gouty spur on the top of the tuber from which the flowers come. No other Cyclamen does so. This gouty spur got blind somehow, and no blooms could come from it; then the tuber made a fresh spur down on the side of it. That spur is now in seed with me, and is a very curious thing in such a family.

Talk about orchard-house Grapes, and then know that Mr. Bird has whole houses on that plan—say without any aid from artificial heat; but like Sir Joseph Paxton, his Vines are all planted out, and the Muscat of Alexandria ripened this season perfectly well, and of the Black Hamburgh immense crops are gathered before it is time to house the Chrysanthemums. The Vine-borders are all above the level of the garden, and are made on the progressive plan of so much in addition every season till it is at the full width, which will take some years yet.

There is another new dodge for getting early Camellia blooms to cut for Mr. Buck aforesaid, by the thousand, and also Indian Azaleas the same. There have been lots of double white Camellia blossoms this last October, so the plan tells soon. It is this—

The large Chrysanthemum-house is 90 feet long and 30 feet wide. Down the centre of this house raised brick-beds have been made for large specimen plants of Camellias. They are 5 feet square and 18 inches out of the ground, the bottom well drained, and yellow Epping Forest loam and a little peat make the Camellia compost, and thus confined and raised the plants are literally one mass of bud bloom. All round the sides of this centre bed are raised pest-beds for the Azaleas, they are 3 feet square and 18 inches out of the ground. Every one of these plants furnishes out flowers in one season worth four times the value of the plants.

All kinds of bedding plants are done there on the same model. We must never lose sight of the flower-beds, go where we may. But, enough. Let us see, or rather say, what is new and best in the Chrysanthemum line. The most splendid-coloured of all the Chrysanthemums, and the purest in colour, is a new one called Jardin des Plantes. It was out last year, but no one grew it properly. It is above the medium size, the shape is perfect, and the colour is just the same as in our own Buttercups; perhaps the finest yellow flower in Nature.

After it I took the seedlings which are yet under numbers, except the first, and they shall be named and described after the descriptions I give of them. The first he called Snowball, but I had it altered to one which gives a far better idea of the flower. You might mistake this flower in your own hand for one from a Guelldres Rose in May, so it is to be booked the Guelldres Rose Chrysanthemum, and, of course, every one must have it. No other flower of the race is at all like it. No. 2, A fine thing in the style of Lisias, but a more brilliant colour. No. 3, Most exquisite shape, imbricately incurved, light bluish colour, and medium size—a lady's flower to the last petal. No. 4, Another medium-sized flower, after the colour of Dupont de l'Eure, but of a different shade and shape, and is thoroughly incurved.

No. 5, A seedling Anemone after Pearl, but superior to it. No. 6, A finely-incurred flower of a peculiar colour, purple outside or under the petals, or rather florets, and salmon and something on the face of it. No. 7, A fine incurved flower, creamy white, and above the middle size. No. 8, A medium size, incurved, and sulphur white. No. 9, A large, deep, rich lilac. A shade lighter than globosa stellaris, and beautifully incurved. No. 10, A deeper lilac than the last, and a medium-sized bloom. No. 11, in the way of Guelldres Rose, but an incurved flower tinged with French white, medium size. No. 12, A finely-incurred Indian red, with a golden back to the florets. No. 13, The last on my list, which is a Pompon, of good habit, and a new colour, which I would call a light chestnut, with a very full centre, and free habit of blooming.

Those were all the seedlings which were open on the last day of October. And now for a selection of all the Good Graciosa among the old ones. The following dozen Mr. Bird calls "trimmers"—1, Queen of England; 2, Princesse Marie; 3, Cassandra; 4, Jardin des Plantes, the Buttercup trimmer; 5, Novelty, the largest of them all; 6, Dupont de l'Eure; 7, Hermione; 8, Marshall Duroc; 9, White Formosa; 10, Yellow Formosa, alias Webb's Delight; 11, Stellaris globosa; and 12, Themis.

My own turn next, and I insisted on a dozen that you might call lady-like flowers, and such colours as ladies prefer for their dresses. All ladies in all parts of our empire avoid foxy colours, and the colours of any thing one could buy at a butcher's stall, as tripe and such gollops as one meets with in Dahlias and Chrysanthemums. I avoid them all, and No. 1, is Vesta; 2, Miss Kate; 3, Hermione; 4, Alma, as being the reddest purple; 5, Cassandra, the lovely Cassandra, pearly white tinged with purple in different degrees in different flowers; 6, Progne, the *g* not sounded; a pretty dark crimson—that is, Chrysanthemum crimson; 7, Wonderful, the third degree of purple, or best, or superlative purple; 8, Princesse Marie, rather too big for a lady's flower, but I know some very big patterns; 9, White Formosa; 10, Madame Lebois, a creamy lilac; 11, Aimée Ferriere, a pure French white tipped with purple, next shade to Vesta; and 12, Marshall Duroc, one of the liveliest in colour.

Then, seeing so many good ones thus left in the lurch, it struck me all at once why not put up a long dozen for aldermen. Every one knows what an alderman is said to be, and to be like, and also what he likes; and I shall take my chance that all the aldermen on the list would jump at my selection for them. No. 1, Queen of England, of course, colour, size, shape, and loyalty, in one bloom; 2, Yellow Queen of England, to make sure of loyalty; 3, Alfred Salter; 4, Novelty, for the button-hole; 5, Jardin des Plantes, but no politics; 6, Princesse Marie; 7, Themis; 8, Cassandra, for a holiday trip with; 9, Triomphe du Nord, to keep him in mind of the Samese Ambassadors with their Indian red; 10, Wonderful, for Lord Mayor's day; 11, Prince Albert, for they all like him; and 12, Madame Poggi, for the sake of ancient customs, her madamship being the most ancient of all that is dark, but not dreary, in Chrysanthemums.

D. BEATON.

FORCING HYACINTHS.

IN reply to "M. A.'s" inquiry as to forcing Hyacinths and other bulbs in a Waltonian Case, I fear I cannot give any very safe opinion. It has seemed to me always a rather dangerous experiment, so very often ending in far too much foliage without good spikes of blossom, or in flowers so weak as to be almost worthless. My own bulbs last winter began to be interesting from the buds appearing quite early in December; but they were, as a rule, never forced at all. When the flower-buds, however, have begun to open and to separate around the stem like a very poor attempt at blossoming, three days in a heated case with a flat top, at about 50°, have brought them always into most charming bloom.

My own Hyacinths have also always been provided with a good quantity of finely broken, almost pounded, charcoal. The beautiful little purple Hyacinth-dishes only 6 inches in diameter, advertised by Millington, are quite first-rate for this; the dark-coloured glass effectually concealing the charcoal pavement, while large enough to contain a very pretty and most interesting group. Mrs. Loudon used to recommend watering bulbs with warm water—a plan certainly efficacious in bringing flowers out. But whatever is done should most certainly be done in the last ten days' growth. For the first six weeks, for my own part, I

always regard with unmitigated regret any increase in the height of bulb foliage. A good healthy six-weeks stock of roots, fed with charcoal from the very first, gives one a fair chance of succeeding with the final ten-days forcing.

The plants should be while forcing in a dampish atmosphere and in the fullest light. The heat should be increased very gradually, and the plants at night should be put in a cooler and quite dark place. Any forcing before the flower-buds begin to show decidedly will probably end in many leaves, few flowers.—E. A. M.

VARIEGATED ARISTOTELIA.

THIS is a very old plant indeed—the variegated form of *Aristotelia Maqui*—a dwarf, evergreen, half-hardy shrub from Chili, which was named after Aristotle by a Frenchman. It comes from cuttings and layers just like the Portugal Laurel if the cuttings are put in under a hand-glass at the end of July, or if the layers are made at the beginning of June. But, of course, regular propagators would get it from cuttings all the year round in heat if there were a demand for it, which there never was, as the variegated one is a very touchy customer about soil and situation, and, above all, about frost and sharp easterly winds, which turn the leaves to foxy colour first, and after that kill them right out if they are not well protected. But the right way to do it and its parent, the green *Aristotelia*, was never generally practised in England. Both ought to be transplanted at the very end of September for the first ten years, and one-half the length of the growth of that summer should be cut back at the time of transplanting.

In a very few years the plants would then be in the same condition as the dwarf evergreen which flower-garden people transplant twice a-year to fill the flower-beds in winter, and to empty them in the spring, and from 3 feet to 5 feet high, and no frost, or wind, or weather would then harm either of them, and both are well worth the trial.

The easiest way for people who have plenty of glass would be to grow the variegated *Aristotelia* in pots exactly in the same way as they do the variegated *Hydrangea*, only that the *Hydrangea* requires much stronger soil, and four times more water than the variegated *Aristotelia*. Then the simplest thing in the world would be to force it like a *Rose* from March to the end of May, then make layers of the new shoots all round the sides of the pot, and they would root faster than a *Rose*.

TANK HEATING.

As it appears from some remarks in your answers to correspondents in THE JOURNAL OF HORTICULTURE, of Octobe. 15th, that the system of tank-heating is just now occupying more than usual attention, perhaps you will allow the accompanying remarks to appear in your most interesting and useful Journal, with a view to eliciting information as to what are the merits or demerits of this system of heating. As I have not yet had any experience in this system of heating, but am just about to adopt it in the warming of a small greenhouse and propagating-house combined, my remarks must necessarily refer rather to what I have read on the subject than to any experience of my own. The advantages of the system as I gather from your excellent little manual, "Greenhouses for the Many," seem to be—1st, cheapness in the erection; 2nd, simplicity in the working; and 3rd, avoiding of danger from occasional neglect or accident (I mean in the water not cooling nearly so rapidly as in pipes.)

The disadvantages of the system are thus stated in a "Treatise on Warming Buildings by Hot Water," by C. H. Hood. "All these plans—i.e., of heating by tanks, have one defect in common with Mr. Rendle's plan, which is the plan recommended in "Greenhouses for the Many." "It is difficult to regulate the quantity of moisture; and by some of these plans, particularly in those where steam was allowed to evaporate in large quantities, there was too much damp for the plants, and by others they were too dry."

As to the advantages I have spoken of, I find—1st, as to cheapness, that the cost will be from £2 to £1 less than heating by pipes (according to the kind of tank I use) in my small house 20 feet long by 10 feet wide.

2nd, As to simplicity, it is so very easy to test at almost any part of the tank, on the plan I propose to adopt, the temperature either by the hand or by a thermometer; and as there will only be

some 4 feet of piping connecting one end of the tank with the boiler, the position of any obstruction to the circulation can at once be detected and removed.

3rd. It is also a great advantage that the water will continue warm from ten to twenty hours after the fire has been extinguished, according to the quantity of water which the tank contains, and the temperature to which it has been heated. Where an amateur has to attend to his house chiefly himself, and where any one desires to avoid, if possible, giving any time or attention to it on the Sabbath—this is, surely, no small advantage.

As to the disadvantage said to belong to the system, perhaps the accompanying ground plan will best explain how I propose in my own case to remove this.

Ground plan of greenhouse and propagating-house, showing system of heating by flue and tank combined.

(a) Stage for flowers. (f) Heating tank.
 (b) Flue. (g) Boiler and chimney.
 (c) Tank path 3 feet wide. (h) Division separating greenhouse from hothouse.
 (d) Propagating tank.

The house I am building is 20 feet by 10 feet, and is divided at (h h h) by a partition, corresponding with the ends, into a greenhouse and propagating-house. The tanks will be two joined together. The one for propagating is 8 feet by 3 feet; the other extending along the front of the house, is 17 feet by 2 feet. They will be of wood lined with zinc, 6 inches deep, covered with galvanised iron with sides of wood rising 9 inches above the top of the tank, to contain the sand, tan, or other materials in which to plunge pots. The longer tank will have two openings about a foot long, one in each house, which can be opened or closed with pleasure so as to regulate the moisture of the atmosphere; and, if these shall not be sufficient for the purpose, evaporating-pans will be placed on the flue. It is thus expected that all difficulty as to over-dryness will be obviated. And, as to over-moisture by help of the flue, which, as will be shown, can be used or not in conjunction with the tank-heating, and by closing the openings in the tank the atmosphere may be dried to any extent; and, in winter, by removing the sand or tan from the top of the longer tank, the whole of this may be made available as well as the flue in giving top heat.

There will be a moveable division in the longer tank at the point where the houses are separated, so that when necessary the circulation of water in the tank may be stopped at this point, and the heat confined entirely to the propagating-house.

There will, also, be a chimney going straight from the boiler up the back wall, so that by means of a damper in this and the flue where it joins the chimney, the flue can be used or not as necessary.

The information I ask for is—1st, Is my plan more ingenious than likely to be practically useful, and to meet the objections said to exist to tank-heating? and 2nd, As to the construction of the tank.

Quoting from your Journal of January 1st, page 192, I read, "We have no preference for wood versus brick tanks, only we think wooden ones, if well made, are less liable to break; and if well hammered at the corners and joints, and a little red lead put there afterwards inside, and no paint given outside or inside, there is no end to their lasting if made of red deal well seasoned and well supplied with water afterwards." Would not the friction in a tank of wood materially interfere with the circulation of the hot water? or may I gather from this that the zinc lining is unnecessary, as I find the cost of this makes the expense of no tanks about double what they would be without it?

I trust some of your correspondents who have had experience in such matters will criticise my plans and remarks, and give their opinion as to the efficiency of wood tanks without any lining.—COUNTRY CURATE.

HEATING BY HOT-WATER IN PIPES.

I AM about to erect a smallinery 27 feet long, by 21 feet wide, and should be obliged by your informing me whether one flow-pipe of 4 inches diameter, and two return-pipes of the same will give sufficient heat if carried all round the house. Also, if by dipping the pipes with an elbow to go under the doorway and then rising again, will interfere with the proper circulation of the water. Also, do you recommend the Vines to be planted inside the house and the front wall to be laid on arches?—**CONSTANT READER.**

[You do not say if your house is span-roofed, or the height. However, that amount of piping will do if you do not contemplate very early fowling; but we advise two flows and one return. You might then so place your boiler at one end, and heat each side separately without interfering with the doorway. Your lowest dip must not be so low as the top of the boiler. We would as well not dip at all, when thus it can be avoided.]

Plant the Vines inside, but see the arches are high enough, and that the inside border is higher than the outside one.

If resolved to take the pipes all round, you might place all your pipes level and so low that you could step over them at the doorway thus—○○○. In so doing, let the pipes rise on one side to the centre of the house some 3 inches from the boiler, and face as much on the other side. One half of the house will then have flow-pipes and the other half the returns.]

THE ROCKERY AND ITS FORMATION.

(Concluded from page 103.)

OF whatever material the bulk of the mound may be made of, care must be taken to have sufficient of the proper description of soil on the outside that is to grow the plants intended to be cultivated there. Most of the Fern class like a moist but open-textured soil; and most alpine plants like a soil partaking more or less of grit, but often more dry and open than is requisite for Ferns—in fact, the latter like it moist and shady, although Polypodium and some other Ferns are often found basking in the full sunshine as well. But it would be as well to secure places for both classes of plants different from each other. And by adding a good proportion of road sand to the compost, and covering the heap to the depth of about a foot, almost any description of plants will be found to grow on it; and by the soil being placed there before the stones, the after-trouble of digging out and putting it in will be avoided; and it cannot be so well done afterwards. Having fashioned the face of the hill, bank, or mound into the form most in accordance with good taste, the stones may be arranged, subject in some respect to the following rules:—

1st. Flat stones may either lie flat, or, if on an inclination, the angle not to exceed 25°. Loose stones on the surface may, however, lie steeper, but very rarely let them lie on their edges.

2nd. All large stones to lie on the side having the largest base, for we will always find the circumference of a stone at the ground surface larger than at any part above; also let all such stones have the appearance of being well set in the ground.

3rd. Do not arrange the stones at equal distances apart, like a tessellated pavement; but let huge lumps form a sort of natural quarry, regardless of the places for plants growing, for these can easily be overlaid by creepers.

4th. In the formation of a piece of rock like a quarry, select flat stones merely fitting to each other, and place them in succession one over the other as nearly resembling what they are found in a state of nature.

5th. Obtain the largest stones you can for the job, and make the most of them. In some cases a thin flat one may represent a large bulky one by being reared on its side against a shrub, which, by concealing the back, gives the idea that only one side of a cube is seen; but this dodge must never be adopted unless the back can be effectually concealed at once.

6th. When water can be had in a stream running something like fifty gallons a minute or more, and with a chance to have a fall of 3 feet or more, a sort of a rustic cascade may be formed where the water falls over a ledge of rock and flows away over a pebbly bottom. Or, if no such fall can be obtained, the water may be made to issue from some apparent orifice in the rock; and Ferns and other plants overhanging its brink, a good effect may be produced.

7th. Avoid all artificial features in water; and if there be

only a very small quantity with a little fall, let that fall over a ledge of rock from some natural-looking spout into a sort of trough below, and the water in this instance becomes in strict propriety "the well." Avoid all pigmy attempts at jets d'eau, for domes, Lotus, Convolvulus, and the whole hosts of artificial forms of playing fountains have no place here; the stream, well, cascade, and such natural features alone being admissible.

It has been explained rockwork cannot well be formed unless in the immediate neighbourhood of trees or shrubs, or on a natural bank already formed; nevertheless, when it is requisite to form one, the planting of such trees and shrubs may be done at the same time; and sometimes banks of rockwork are made to hide unsightly objects, and shrubs being placed on their summits as well as their sides, a good effect is produced. And I would not advise any piece of rockwork to be without evergreens of some sort or other, as Ferns and herbaceous plants look so bare in winter. One of the best shrubs for covering a steep bank is Cotoneaster microphylla; and one of the best instances of its being converted into such a purpose is seen in Birkenhead Park at the head of a lake, where an abrupt bank 12 feet or more high is covered with this trailing shrub, and looks remarkably well. Savin may also be used in like manner; and at Redleaf the Juniperus repens is made to cover a considerable space, but this plant is less plentiful than Cotoneaster and more choice of a situation. However, something or other must be added to the herbaceous plants to give it a clothed appearance in winter.

In giving the above general views on rockwork, I have not mentioned the use of roots and stumps of trees, which are often converted into fanciful mounds or banks on which plants thrive perhaps better than anywhere else, the decaying timber affording that nourishment so much relished by alpine plants, creepers, and Ferns. But roots are, properly speaking, a perfectly artificial affair, and scarcely come under the class of rockwork, that I would hardly advise their being used in conjunction with stone, unless in such a position as will insure of their being speedily covered with some permanent plant. And do not by any means allow them to appear through the foliage, while stones may do so with perfect propriety, and, in fact, it would not be proper to conceal them entirely at any time; but a judicious concealment of their bases sides, and when they lose themselves in the ground is at all times advisable.

Of the class of plants proper for such places, every one has his own particular favourites. In damp, shady places, Ferns are especially suitable; while in more sunny places some alpine plants may feel more at home; but it is, perhaps, as necessary to say here what it is advisable to exclude, as well as what to cultivate; and one of the worst enemies to contend with in a piece of artificial rockwork is the wild Convolvulus, which it would be proper to guard against in the formation of the ground. The common or herbaceous Vine is also an unpleasant-looking plant in winter, and overruns every thing in the growing season; but the narrow-leaved variety is better, and Vicia elegans, the variegated one, is worthy of a place anywhere. It would, therefore, be prudent in planting a rockery to avoid such plants as are likely to be troublesome hereafter; for when once the roots of such plants as Convolvulus and Vicia get underneath and amongst the stones, it is no easy matter to get them out. It is better, therefore, to endure the thin appearance the planting may have for a year or so, rather than plant such unruly plants for a temporary purpose of serving that time. Some annual creepers would do better and be less trouble, taking care, however, that the plants intended to occupy the site be not injured by those robust growers which overtopping everything at the most important growing time, would quickly injure if not kill all beneath them.

In concluding this somewhat long article, I would advise the intending creator of a piece of rockwork, to visit the best-formed feature of the same kind in his immediate neighbourhood, and taking a lesson or two also out of Nature's open and inviting book, he will with the aid of the above remarks be able to see what he ought to do, and, which is of equal importance, what he ought not to do. The Crystal Palace with its extensive flower garden does not present much in the rockery way that is useful to copy in a small place, although the mounds facing the lower ponds contain some useful hints; and tourists and others who wish to see rocks in their primitive state, may see good examples that way at Tunbridge Wells; but I have already quoted sufficient examples, and if I added another, I might say that the public park at Sunderland is formed by the side of a disused

quarry, and the face of it as well as the mounds of debris is worked into good account. But most districts afford some examples of this class of gardening; only, as I before stated, many of them are sadly at variance with everything of a like kind we meet with in Nature, and although in the miniature way in which we attempt to copy that grand original, we have no chance to compete with her best works, let us endeavour to imitate those of a more moderate kind, and, above all things, let us beware of appearing in direct opposition to her.

J. ROBSON.

COCOA-NUT FIBRE AS A SOIL FOR FERNS.

A CORRESPONDENT alludes to cocoa-nut refuse as a soil for Ferns; would you kindly direct me how to use it—whether mixed with clay, and, if so, in what proportion?—T. R. LANE.

[The cocoa-nut refuse is the best invention of the day for growing all Ferns which are in anywise difficult to grow, and, what is most singular, ten inventors made the discovery nearly about the same time, and we ourselves have been proving as many cases as we could. We did prove every word to be true, and we sent the proof plants to Mr. Eyles for the Royal Horticultural Society, who is very fond of fine Ferns, and he was astounded at seeing how they rooted all over, and in and under every morsel of the "fibre" as if they never could have enough of it.

It is to be used exactly as peat and sand are used now for Ferns. It is the substitute for both peat and sand, and for very delicate little Ferns nothing else is needed; but for all above the smallest, one-sixth, or one-eighth, or one-tenth of the compost should be the best yellow loam, pounded as fine as it can be made. That would do for the next three degrees of strength of plant; and for very strong Ferns and for hardy ferneries the compost should be one-half cocoa-nut refuse and one-half yellow loam, without turf, or lumps, or any sand, and no peat.

This fibre, if the paper makers do not swallow it up, will make a revolution in the growth of fine Ferns, at least so we are told by the inventors.]

GAZANIA SPLENDENS.

I FAILED again in crossing *Gazania splendens* and *rigens* at the autumnal equinox; but the old plants have suggested a way of using splendens, which I hasten to notice, in order that it may have a chance before the frost cuts up the old plants now out in the flower-beds. The older the plants are, the more freely they seem to bloom and the less growth they make, and they make hanging-plants easier than any kind I know: hence, that which I most suggested itself is this:—

Gardeners down in the country who have much to do in the way of furnishing summer plants in boxes for the outside of windows, and for flats and recesses about houses and castles, have one of the best furnishing summer plants in the country in *Gazania splendens*, if they would now take advantage of the longest and strongest plants they have in the beds, and which they mean to leave out to the frost. It is a very simple proceeding now; but at the end of next May it would be one of the best moves one could make, and then there will be nothing to do it with unless the best of the old plants are lifted and saved over the winter, for autumn or spring-struck plants of it will be of no use for what I mean—and that is, that a row of such old plants should be first planted close to the outside of the plant-boxes, their heads or branches to hang over the box and to trail down half a yard at once; then to fill the box in the old way, and to tack or nail the strongest of the branches of splendens along the front of the box at the bottom to keep them from being too much shaken by the wind. They will flower most profusely the whole length of the shoots from May to November; mine, out in pots on the window-sill, have not yet done blooming, and they hang down and grow downwards as freely as if they were trained to do so.

I almost blush to say that a box of Tom Thumbs, or of any Scarlet Geraniums, fringed in front with a broad margin of this yellow, would be just in the fashion, and fashion will have its sway; but yellow and scarlet are not the best two colours to place side by side by any law of contrasts. But, certainly, the *Gazania splendens* is thus the best outside trailer or hanging-down plant I have yet seen tried.

Mr. Kinghorn's plan of having aprons of *Nierembergia*

gaëllis in front of boxes of his lovely *Christine* is very good looking to the sun, and that would be the best aspect for the yellow apron; but the plant is so hardy and so accommodating that any aspect round the compass will do, for Scarlet Geraniums do not look at all well against red brick houses; but for stone, or stucco, or white bricks, nothing is so telling as scarlets and yellow, except one thing, and that thing would suit *Gazania* in bloom to the very shade of perfection: the thing is a soft purple with a tinge of lilac in it; and of all the colours of flowers that is the richest against a white background, and the best to contrast with *Gazania splendens*; always minding that both colours are resting on green, which makes all the difference from the notions of Chevereil, whose book on colours is the very worst for flowers of all the books that ever were printed. The purple and lilac combination you will find in the *Unique Geranium*; and Rollison's *Union*, as it is erroneously called, is one of the very best box Geraniums we have, if you take old plants of it and keep it well down in the box by training. Just try the *Unique* and the splendens as I say for once, and then try if ever you can give them up afterwards.—D. BEATON.

FRUIT TREES IN POTS UNDER GLASS.

WHETHER a tree be planted in the earth or in a pot, it requires for its perfect development—1st, Substances containing carbon, nitrogen, and sulphur, and capable of yielding these substances to the plant; 2nd, Water; and lastly, Soil, to furnish it with inorganic matters. In addition to the above, there must be plenty of air and light. If all these be attended to, there need be no fear as to the result.

Whatever may be the opinions and experience of persons as regards pot culture of fruit trees, the following facts cannot be disputed; they can be attested by persons far and near. Six years since I purchased of Mr. Rivers fifty Peach and Nectarine trees, together with a few Plums and some Pears; the latter I do not refer to, although I had a very good crop. These Peaches, Nectarines, and Plums were potted and bedded out against a south wall. By the end of autumn the wood was thoroughly ripened, and full of bloom-buds. By the following spring I had built a lean-to house against this wall 110 feet by 15 feet, to be used afterwards as a vinery. I parted off 50 feet, and placed in this the Pears against the wall; the Peaches, Nectarines, and Plums in front.

Now mark this, neither I nor my gardener knew anything of the culture of fruit trees in pots farther than having paid Sawbridgeworth a visit; yet the very first year we had the most magnificent crop, the branches being laden to the earth, the fruit quite as large and as well flavoured as any on the walls. I almost forget the amount of fruit, but I think it was about a hundred dozen.

The ventilation was perfect, and every pot's surface was covered with about 3 inches of rich black compost; the gradual decay of which fed the plants at each meal with a clear solution of carbonic acid, ammonia, disintegrated earthy inorganics, &c. This surface dressing I believe to be half the battle. And possibly at the time to which Mr. Robson refers this method might not have been adopted. It occurred to me, as I dare say it did to many others, on reading Liebig's article on cremacausis—*i.e.*, slow combustion or decay. I seldom recommend liquid manure for the long run; it seems to suit Vines, but is apt to produce surfeit and an excess of raw sap in Peaches and Nectarines. When a dry atmosphere, to assist exhalation, and plenty of sunlight to fix the excess of nutriment is indispensable, shoddy (woollen fibres from a cloth mill) forms a capital slow decomposing layer to place over the surface of the pots to prevent evaporation; and any slow-decaying compost, not likely to get hard and cake, forms a good palium above this. I have such a supply of water and such facility in applying it that I am not particular about evaporation. I should think the outside of the pots might be covered with some material better than hay, and something that might act as a nonconductor of evaporation as well as radiation; say boiling coal tar at 2*l.* per gallon, creosote 6*d.* per gallon, or jet varnish 1*s.* 9*d.* per gallon.

We are rather famed for our fruit culture, one gardener carrying off first prize at the Crystal Palace, and at a neighbouring fruit show this season seventeen prizes at once. Is it reasonable to suppose that if pot culture did not answer I should at this time have nearly a hundred fruit trees in pots?—SCATTORON.

THE IN-DOOR PLANT CASE.—No. 1.

In commencing a series of papers on the In-door Plant Case, my first endeavour must be to describe these cases, and to say what they aim at effecting. For this I must first glance back at the many endeavours which have at different times been made for enabling those who are fond of plants to grow or force stove or greenhouse flowers, or even to preserve such as they may have bought for a long time in freshness without a proper hothouse.

For stove plants and for forcing, heat was, of course, required, and most of the means that were tried for this proved to be attended by such objections as rendered their general use all but impossible. Gas was required, or a lamp, with oil that might spill, or lights that might go out; and these cases, too, were constructed much too low to enable the cultivator to produce a gay display of plants.

It always seemed to me, however, a certainty that something might be done. It was quite impossible but that a miniature house could be constructed for the little stove plants as well as Crystal Palaces, and enormous buildings for Victoria regias. So while others effected the great, I thought I would try the little; and being myself intensely fond of flowers, and unable for a time to take care of them out of doors, I turned all my efforts to growing them in the house.

These plant cases, indeed, never could succeed till some one had time to watch them day by day; looking out for their defects, tracing those defects to their causes, and endeavouring to remove them as fast as they were discovered, and this could hardly have been done except under circumstances such as mine have been.

These cases are now the simplest to manage that can possibly be conceived; but this simplicity is only the result of at least two years' incessant experimenting and balancing their resources, following also on a whole life of gardening, for I remember having the care of plants, and at one time growing some very charming Orchids, even when quite a child.

The In-door Plant Cases are now I trust, sufficiently perfect in their working details to afford a very great

delight to many who are debarred from all out-door gardening, or who cannot have a large hothouse.

One of my cases was exhibited at Kensington Gore at the flower show there last week; and though the 6th of November is not a good time for flowers, it will give an idea, perhaps, to those who saw it, of the actual grouping, and of the kinds of plants that are adapted for this sort of culture.

Many persons have, also, some particular kind of flower for which they have a very special preference, and as far as my experience goes, most kinds may thus be grown in different degrees of heat, different degrees of air, different degrees of light, and different degrees of moisture. The variation of one of these various requisites often turns the scale, and each can be regulated to any point whatever by the simple use of the simple means provided.

I hope in succeeding details to give a list of plants adapted for such culture, whether stove or greenhouse, or only hardy plants and bulbs to be hastened on; and having begun at the beginning, and so worked up myself, I am prepared by experience for most of the small disasters that befall such florists.

Any practical difficulty that arises in actually working cases, I shall be also delighted to try to meet and if possible to point out a remedy; only I give fair warning that *adaptations* of my system will generally fail, for no one can tell the number of little requisites, proportions, size, make, shape, boilers, pipes, &c., which have had to be considered, and to be put together to make such a structure as may adapt itself to every season equally, and to each style of plant, while being yet easy and simple in the user's hands.

The temperature of these cases may be raised to 90°, going down to 65° in the course of twelve hours. It may otherwise be made to reach 65°, and to fall to about 50°, or it may be kept at the temperature of the room it stands in. Moist stove heat, or dry, warm air, may be also regulated with equal ease and accuracy.

As I keep four cases in full work, one of which acts as a stove and another as a warm greenhouse, I shall hope to carry on the management and description of the two

alternately. My other cases, generally, are kept unheated, unless during a sudden frost, or in a long-continued time of damp or foggy weather.

I think it is very essential for all purposes, to have

cases such as may be heated, if necessary. If not warmed for months no injury can arise, but if heat is wanted and cannot be given the consequences are embarrassing.—E. A. M.

A FEW DAYS IN

THE CHIEF SECRETARY'S

If the Viceregal Lodge be a mile from the entrance gate, the lodge of the Chief Secretary is considerably further northward. It well sustains the characters of *lodge*, being almost concealed on the east side by trees and shrubs. I hardly know how it was, but I had merely a glimpse of the west or lawn-front of the house; that glimpse, however, conjuring up the ideas not of seclusion and retirement, but of exposure, freedom, and openness in the character of the landscape. The scenery of the park, the views of the country adjoining, and the more distant Dublin mountains, all demanding us to lift our eyes from the ground near us and to look further a-field. The very openness in the lawn front seemed to be somewhat emblematic of a distinctive feature in the character of the Right Hon. Baronet Sir Robert Peel, who, as Chief Secretary, occupies this lovely residence. Leaving out of our consideration the great fields of politics and social amelioration and advancement, in which, we doubt not, suitable openness and activity will be displayed, signs are already appearing that the farm and the garden will receive a portion of that energy and taste which we hear rendering Drayton Manor illustrious for what is beautiful in Nature, and classical and refined in art.

In front of the mansion we just noticed a number of flower-beds well filled, no doubt; but though we were not near enough to notice the arrangement, we could not help wishing that in such a place they were either swept away and their place occupied by the green grass, or a few choice shrubs; or that if flower-beds there were to be, they should be comparatively few in number, and sunk so much in a panel as not to be seen until you came near them. This latter plan would be particularly desirable if there was an invalid in the house that could not well go further to see flowers growing—in fact, in such a case, we would break down all our prepossessed ideas as to fitness, and have flowers anywhere and everywhere, so that their soothing influence might be seen and felt.

Some people act as if thoroughly convinced that a flower-bed, a rustic basket, and an artistic vase can never be placed wrong in a garden; hence, it is no uncommon thing to meet with a flower-bed marring some beautiful scenery, or destroying the effect of a beautiful tree because you cannot see the base of its column or bole. Or you find a beautiful Italian vase perched in front of a rustic-roof summer-house, or you find a mass of roots and flints thrown up in front of a Grecian mansion! Would that some one of undoubted taste and commanding influence, would tell us when, and when not, flower-beds should be placed close to a mansion.

If not deceived in our glimpse, the very reasons that told in favour of the flower garden at the Viceregal, told against it here under present circumstances. Two we will mention, keeping in view the objection above stated as to invalids. The first is, that we can hardly fix our attention upon the beauties of the sur-

IRELAND.—No. 3.

LODGE, PHENIX PARK.

pleasantly but harshly on the unity of expression; and thus one form of beauty is led to impair instead of to enhance another distinct and separate form of the beautiful. The second reason is, that too much of one form of the beautiful, clustered near together, tends to produce a feeling of satiety, and thus far lessens instead of promotes enjoyment. Something like a hundred yards from the mansion a nice gate opens into a nice walk in the kitchen garden, so wide and so long, and so rich in colour from very wide ribbon-borders at the sides, that the open beds near the house must be very fine indeed not to lose by comparison, and be altogether forgotten until the visitor or the resident returns to the house again. Were the distance between the beds and the ribbons greater, and that space peculiarly enticing from objects of the rare and attractive in sylvan beauty, the contrast and comparison would not be so rudely thrust upon us. After all, however, so long as the kitchen garden is thus made so ornamental, the flower garden at the house will never be a telling feature until its beds are more attractive than the massive ribbons, and it is either shut in from the view of the park, or treated in some distinct and separate way, as a panel, to look as well in winter as in summer.

We met our new friend, Mr. McNeill, the talented gardener, near this gate, having had a Paul Pry peep over the kitchen garden before we had the privilege of finding him. The kitchen garden seemed much smaller than at the Viceregal; and, on expressing our surprise that so much space could be devoted to flowers, Mr. McNeill told us that they could get the coarser vegetables at the farm. The ground, however, was well cropped, and we noticed in particular that the Celery here, and elsewhere, was very forward, and earthed high up in Ireland. There seemed to be no end to the ribbon-borders. Much the same style of planting was adopted as at the Viceregal, with the addition of separate and distinct groups at the corners; and crosses and stars very nicely and tastefully done. The number of plants wanted must be immense. The kitchen cropping being shut out, the whole looks almost like a rich flower garden. We seem going back to olden times, when the walks in the kitchen garden were bounded by espalier or trellis, and a flower-border in front of them. These mixed borders were well enough in their way, but for massive effect could bear no comparison with the ribbon in its glory, though the glory be but short-lived. The rows here, as well as at the Viceregal, were clear and distinct—not so close perhaps as some of us would wish, though having peculiar advantages.

Ribbons are even more general in Ireland than in England, and there is one thing in which, with one or two exceptions, all we have seen would be improved, so far as we think, though as a mere matter of opinion, other men may with propriety think and act differently. The improvement in our opinion would be the having the borders sloping regularly from back to

FIG. 1.

FIG. 2.

rounding scenery, and upon flower-beds so placed on an open lawn, without any background near at hand, at one and the same time. Nay, that the very attempt to do so breaks in not

front, if to be seen on one side only. In these and other wide borders we have seen, the back rows are tall, to blind what is behind them in the way of the purely useful—consisting of

Sweet Peas, Hollyhocks, Fuchsias, &c.: but some four, or five, or more rows next the front are more uniform in height, and, therefore, present almost a level surface to the eye, which we know some people like not only in ribbons but in beds. The lines of colour are equally well seen when looked at from either end, but we do not think they are so well seen as you walk along by the side of them; and more room is required to keep the line of colour distinct than when on the slope. This is no new idea of ours; for some years ago, when giving a kind of review of *Shrubland*, and noticing the ribbon-border, which, backed by evergreens, and having on the other side of the green drive a steep romantic bank, was yet as level as a level could make it, we could not help thinking that the colours would have been more telling if the back lines had been the highest, and the front the lowest.

Figs. 1 and 2 will give a rough representation of what we mean; even if the lines sloped more than in *fig. 1*, the different rows would show more as you went along the walks, which is supposed to be 10 feet wide, and the borders 15 feet. *Fig. 2* is something like the way the ribboning is done at the Phoenix Park, and we know it will have many admirers. There is no need to illustrate a wide flat border, because a strawberry-bed in flower would show that well enough. Our own opinion is, that very wide flat ribbon-borders are a waste of energy, as the distinctive markings of the lines are apt to be lost. This is not so likely to be the case with borders planted as *fig. 2*, because the higher lines at the background reflect the light back on the lower level ones in front.

Of course, a sloping bank could be made of plants somewhat similar in strength if the ground was first made sloping. *Fig. 1* is on the supposition that the plants are selected for their different rows, according to their natural heights; and here lies a little difficulty, as some plants will not grow equally strong every season, and, if a line—say near the centre, was unduly depressed, it would spoil the effect of the whole. Some friends also complain that when the suitable heights are secured, the rows can hardly be kept distinct; but there will be little difficulty with this if stout sticks are put in as thick as a finger every two yards, but out of sight, and connected with small thread cord to keep the rows from intertwining and mingling with so much that is magnificent in these ribbon-beds. We should like much if Messrs. McNeill and Smith would try a small border sloped to the Box next season, and give us their candid opinions of the two systems, for after all we may be wrong in this matter.

Of course, what has been said has chiefly reference to ribbons made with straight lines, or at least lines parallel to the walk or the boundary; but the same principle will apply to ribbon-borders, with winding lines along the centre, but straight lines at the sides to suit the straight walk, if straight it be. The same gradation as to height will also apply to what are called spotted ribbon-borders—for instance, when the ground colour may be Variegated Alyssum and raised spots on it of blue, orange, scarlet, and purple. The highest spots should be farthest from the eye if the border is to be seen on one side, and in the middle if seen on both sides. Considering the immense quantity of fine ribboning here—so much as would surprise many English gardeners, I just throw out these ideas, and leave them to make their way if deserving of consideration.

Besides these fine ribbons I noticed beds of fine Stocks, and splendid China Asters, and some wonderful flowers of a very dwarf kind, the stems only a few inches above the ground. Everywhere the greatest neatness and cleanliness prevailed, there being a place in the reserve compost-ground for rubbish of all kinds, and none to be seen anywhere else. It was evident that there was an honourable and friendly rivalry between these artists of the Phoenix. Here again I met splendid plants of *Chrysanthemum trained*, and, I believe, cultivated in the same way as referred to the other week; and which, before they were in bloom, it would puzzle most people to say which were the best, if even then. Some of the plants in the middle of September were from 1 foot to 5 feet in diameter, and the mass of firm shoots scarcely 15 inches to 18 inches in height. Pelargoniums, too, were splendid, one fine house full of large plants, and plenty of smaller ones elsewhere. The larger plants were from 3 feet to 4 feet in diameter now, and would be at least a foot or 18 inches more in May and June. I rather think none of these had bloomed this season, but were treated much the same as these mentioned the other week. The shoots were very equal in strength all over the plants, and the leaves told of firmness and the highest health, though at this season not too large in size. They were all tied down to a ring, or a series of

rings, and not a stick of any kind used, unless the two that crossed the pot to support the circular ring.

Besides these *Greenhouse-houses* and some frames there were only two small plant-houses—one with two wings and a circular domed one for its centre, which might have done very well if the wings had been of any size; but being mere names or makeshifts from being so small, plants could not be expected to do well from the constant variations to which they would be subjected; one great advantage of a good-sized house being the somewhat equality of its temperature as compared with a small one. The other house was a small lean-to, where as we entered, the wind being boisterous, a fine plant of *Acaia Drummondii* was thrown down, as the pot in which it grew was standing on another too small to meet the force of the gale. Notwithstanding these disadvantages, remedied in some degree by the opportunity of placing plants in the forcing-houses (to which we will presently allude), it was very pleasing to meet, not only with a good general collection of flowering plants for winter and spring—as *Camellias*, *Azaleas*, *Primulas*, *Cinerarias*, *Euphorbias*, *Justicias*, &c., but a number of very fine specimen plants, which, though not wonderful for size, were beautiful for their compactness and high health and vigour. Among these we noticed fine plants of *Rogiera cordata*, *Adonia vernalis*, *Cyrtocera reflexa*, *Allananda Schottii*, 5 feet by 4 feet; *Cyrtanthera magnifica*, 3 feet by 3 feet; *Hibocidium lanthornum*, 4 feet by 4 feet; *Medimilla magnifica*, 4 feet by 3 feet; *Stephanotis floribunda*, 5 feet by 3 feet; *Passocunia laniflora*, 5 feet by 4 feet, very fine. A fine plant of the hand-one-foliaged *Agrostis sinuata* was showing bloom, supposed to be the first time it has bloomed in Ireland.

Among fine, young greenhouse plants, *Heaths*, *Pimeleas*, *Epaeris*, &c., the following were, perhaps, the most beautiful specimens—*Acaia Drummondii*, 4 feet by 4 feet; *A. grandis*, 5 feet by 4 feet; *Acrophyllum venosum*, 3 feet by 3 feet; *Adenandra*, of kinds, such as *fragrans*, *speciosa*, *umbifera*, &c., averaging 3 feet by 3 feet; *Eriostemon buxifolium*, 3 feet by 3 feet; *E. cuspidatum*, 5 feet by 4 feet; *Erica Cavendishii*, 4 feet by 4 feet; *Pimelea Hendersonii*, 3 feet by 3 feet; *P. decussata*, 3 feet by 3 feet; *Rhynchospermum jasmiioides*, 5 feet by 4 feet, &c.

The sight of the back settlements would have done some of our grumblers good, who never can get a place for anything, as they would find that even under the shadow of royalty here, many a make-shift must be made. Fine young plants were standing under the protection of old, ricketty, worn-out frames; and as we understand water is a little scarce in the park, some of the best compact greenhouse plants were half-plunged, or more, in ashes, in a bed, and by posts and rails back and front the means were provided for placing some old sashes a yard or more above the plants, so that whilst they had a free current of air all about and among them, they would still be protected from the soakings that drenching rains would give. The force of the sun's rays could easily be blunted by dulling the glass when desirable; though most of the old glass would be dull enough for anything. It is often to places like this that we must go to learn to make the most of everything. "Never be beaten, never give up," should be the watchword of the gardener.

All kinds of small fruit had been plentiful and good, but like as with us Pears and Apples were scarce, though the latter was pretty fair, if we may judge from the best part of a bushel lying on a walk, which the gale of that day, the 13th of September, had rattled down. The wall trees seemed in excellent order, and a high Peach-wall pre-eminently so. It did one's eyes good to see them, for such a crop of fine fruit even then left we were not privileged to see this season, and on looking over the wall we could see the knobs from which many fruit had been taken. We regret that there and then we did not get from Mr. McNeill all the minutæ, and whether he covered or not, and how if he did. We have no doubt that when he sees this he will tell us all about it. Such Peaches out of doors have been a rarity this season; for elsewhere they seemed as scarce in Ireland as in this neighbourhood.

The great proportion of tender fruits, chiefly Grapes, are grown in a long range of iron curvilinear houses, of which the enclosed (*fig. 3*), is a simple section. I forgot to ask if ever the houses had been used for Pines, for they would answer admirably for the purpose, as from having pipes below the beds there would be no want of a regular bottom heat. The section shown represents shelves in the bed; but in some of the houses the surface seemed dry earth to keep the Vines from damping, and

we were given to understand that after a lot of clinkers, &c., above the pipes, fermenting matters could also be introduced if deemed advisable. In such beds we can well conceive the lots of under-

work was done in February 1858, and ever since we have had good crops of finely-coloured Grapes, and no shanking." The mode and the results speak for themselves. R. FISU.

FIG. 3

crops, as Dwarf Kidney Beans, or even of Cucumbers and Melons if deemed desirable. In some of the houses where the Grapes were cut or not quite ripe, we found numbers of plants in pots and in excellent health, and for these and whatever may be grown in the season beneath the Vines, a good chance is given, as the rods of Vines were about 6 feet apart. Mr. McNeill complained of the Chasselas Musqué cracking, but the later Vines showed every sign of coming to first-rate perfection. There were two peculiarities in these houses. First, by rising a couple or three steps at the doorway, the back path is sufficiently elevated to enable a person to work in the bed conveniently. The second feature is, that without greatly encroaching on the width of the back pathway, and by means of arches in the back wall, a narrow pit is made at the back, in which the *Musa Cavendishii* is grown neatly, if not altogether, the whole length of the range, and was producing some fine clusters of fruit. Asking if any heat could be applied below the roots, Mr. McNeill shook his head in the negative, as much as to say, "I wish I could get it." We understood from another quarter, that in these royal gardens the current expenses and what little alterations it may please them to make, are defrayed by those holding office for the time being; but, that for all large alterations and improvements, an application must be made to the State for a grant, and there is generally so much circumspection, and circumambitibus, and circle-go-round-and-round, without coming to a practical decision, that unless for some great object the trouble and worry exceed the advantage.

Before closing this gossiping letter, we must notice one more lean-to vinery in front of Mr. McNeill's cottage, where the Grapes, chiefly Black Hamburgs, were very fine and as black and well coloured as they could be. A section is given by Mr. McNeill's kindness. Fig. 4. The Vines grew well enough and

FIG. 4

produced good bunches and berries, but were deficient in colour and given to shanking. The remedy applied we cannot do better than give in Mr. McNeill's own words. "My predecessor having put in a large drain 1 feet deep along the front of the border, I had only to take out a cut, 4 feet deep, the whole length, then with steel forks work up to the front wall, pegging back the roots as we went on, and taking care to keep them moist by rolling them in damp moss as each Vine was disentangled. We took up in this way some half-a-dozen of Vines at a time. We then thoroughly drained the bottom, giving it a good slope to the front drain, and then placed over it some 18 inches thick of brickbats and rough lime rubbish. On this we put 6 inches of fine lime rubbish rammed hard, and on that a layer of fresh turf, grassy side downwards. So much for drainage. Having laid on good compost for 20 inches deep, over that we spread out the Vine roots, raising all the points a little to allow for sinking, and over them put about 8 inches more soil, so that the border when finished had about 28 inches depth of soil. This

MUSHROOM CULTURE.

PREFATORY REMARKS.

For several years past my "better half" has been putting the question to me, "Why do you not instruct John (the man we call our gardener) how to grow Mushrooms. You know very well how they should be grown?" I have been accustomed on such occasions to state in a hesitating manner (my conscience all the while upbraiding me, and saying as plainly as possible, "you know nothing about Mushroom growing;"), that I would "see about it." I did on such occasions see very plainly that Mushroom growing was no joke, for on looking into those ponderous volumes of McIntosh, into the one heavy volume of Thompson, into various Numbers of THE COTTAGE GARDENER, into London—in short, bewildering my brains to an enormous extent, I found so many ways of getting to the end, that my resolution failed me, and instead of trying some of the methods recommended, I relapsed into a pleasant apathy, and thought, without even making use of my convenient phrase, that I would see about growing Mushrooms when I could make up my mind whose method of growing them was the best. Well, I did not see about it, and I did not instruct John how to make a bed, till, I think, on the 18th of last May I saw in a contemporary an account of a visit to the gardens at West Hill House, Highgate, and a short description of the method of growing Mushrooms there. I promptly wrote to Mr. Young, the gardener there, to clear up a point or two, which he at once did. I have had perfect success, and have for some weeks thought of giving you in as short a space as possible how and what I have done. A useful article on Mushroom growing in No. 32, but of the same lengthy, vague character as those given by most gardeners, has determined me to condense in as few lines as possible, how I grow Mushrooms.

MY BED, AND HOW I MADE IT.

About the 20th of June last, I gave orders to my groom to save a one-horse load (say twenty bushels) of droppings from the stable, and to take out all the long pieces of straw, leaving the short pieces mixed with the droppings. This load was placed in an open shed in case of very heavy storms coming on to saturate it. I then bought from the gatherer twenty bushels of droppings from the road. This being mixed with sand checks the too rapid fermentation of the stable-droppings. This I mixed with the above, and formed it into a heap like a haycock. Fermentation, as the doctors say, "supervened," and on the 28th of June I reckoned my materials ready to make my bed.

I fixed upon my cellar as the place to make it in. This being dry, light, and, for a cellar, moderately airy, temperature all the year round from 50° to 57°, I had a bottomless box prepared, made with inch boards, 7 feet long, 4 feet wide, and 20 inches deep. Into this I had my forty bushels of horse-droppings placed, hammering them down with a rather heavy mallet as they were emptied into and spread about it. The surface was then levelled, a thermometer placed just under the surface, and the bed left. On the 6th of July I found the thermometer down to 70° (it should not be lower than 70°, nor higher than 75°). I then took half a bushel of good spawn—mine was the Miltrack—and planted it in pieces from about 2 inches to 3 inches in diameter, and 1 inch thick, poking it in just under the surface with my fingers. I then took some light mould, not dusty, but rather dry—it was refuse pot mould sifted, and spread it over the bed 3 inches deep, hammering it down with a heavy spade, so as to make the surface quite smooth, hard, and level, and the depth of mould thus pressed down was about 2 inches over the spawn. About the end of July the Mushrooms began to appear, and ever since the middle of August this small bed, 28 square feet, has given enough not only for the wants of my house, but enough for my neighbours. The bed is at this moment crowded with Mushrooms of all sizes, the small ones are so thick that they look as if white Mustard seed had been strewn over the bed. Any one with a cellar not too damp, or a shed not too airy, may grow Mushrooms in boxes of the depth given as above. A box 6 feet long and 3 feet wide would give a great abundance, and, I believe, that no uncertainty in their culture exists, if people will do as I have done.

It will be seen that no covering is used, and what a nuisance

it used to be to have to remove the covering of hay before you could gather a few Mushrooms. I have watered my bed three times since it was made, for I found the surface getting quite dusty in August. I gave it each time about three gallons of water, warm (temperature 90°), sprinkling the surface with a fine rose.

I can tell your readers that a Mushroom-bed placed as mine is, in a light, dry place, is most interesting, and the flavour of Mushrooms thus grown without covering is most delicious. I have never eaten any equal to them.

REQUISITES FOR GROWING MUSHROOMS.

1. A bottomless box 20 inches deep and from 3 feet to 4 feet wide, and from 5 feet to 7 feet long. If your wants are great, have more boxes.

2. A dry cellar with a minimum temperature of 50°. This will do for a crop all the year round. The temperature of my cellar is now 51°, and the Mushrooms are growing freely.

3. In default of a cellar, a close shed with thick walls either of brick or stone, in which the maximum temperature in summer is not more than 60°. A place of this kind will do for Mushroom culture in spring, summer, and autumn, but not for the depth of winter.—AGARICUS.

BLOOMING TACSONIA MANICATA.

At page 31, Vol. XXV., of THE COTTAGE GARDENER, Mr. Beaton offers a donkey to "the first who will show him *Tacsonia ignea* and *T. manicata* in bloom."

If no one has hitherto claimed the donkey, I can claim half of it by showing Mr. Beaton *T. manicata* in bloom. The flowers are about the colour of *T. mollissima*, but single. It is growing at the east end of a small conservatory, where in severe weather the temperature is never above 40°, and last winter was often below 30°. It has been grown chiefly for its beautiful foliage, which is always clean. Neither red spider, green fly, nor thrips will touch it. I have sometimes used its leaves for garnishing dessert.

The cause of its blooming I take to be this: Two or three of the largest and strongest shoots were trained some 12 feet or 15 feet beyond the usual limit, to cover a bare rafter, but without the least idea of making it bloom. These shoots were allowed to grow unstopped until they were rather wild. When, contrary to my expectation, about the middle of August it showed bloom and has been blooming ever since, but it is nearly over now, November 1st.

When done blooming I intend to prune it back very severely, and will train some outside next year; but no stopping. It is very vigorous. Would Mr. Beaton recommend root-pruning? —LARIX.

[No. Never root-prune a *Tacsonia* after it comes to a blooming mood, or rather after undergoing your own most judicious way of growing it. If all would exhaust climbers of all kinds by long growths and no stopping or shortening of the main shoots at winter pruning, they would all bloom, Rose climbers among the rest. Mr. Beaton would rather not cut a donkey into halves, but wishes "LARIX" to make haste and let us see the flowers of *Tacsonia ignea* also, and then he shall have the donkey —the very one Mr. Judd refused.]

SALT AS A MANURE TO PEACH TREES.

In your Number of May 14 is an article on the culture of the Peach, from the pen of Mr. Robson. He there gives his opinion that salt may be used as a manure for Peaches and Nectarine to considerable advantage. I propose adopting his recommendation for my Peach trees, and should be obliged with a little advice upon the subject, which may be useful to other subscribers to your Journal.

My Peach-house is 30 feet by 12 feet, the trees are trained on a wire trellis parallel to the glass. They have been planted about six years and have succeeded tolerably; there was no border made for them, nor has the soil been renewed or manured. The natural soil of the garden is a black mould about 2 feet deep, on rock of the oolite formation.—A STUDSBER.

[As salt is one of those convenient manures which can so easily be transmitted into the system of the tree during the growing season, it is best only to apply it then. But, as you say your trees show symptoms of requiring assistance, it would be

advisable to give them some well-rotted manure in the present autumn, and two or three times during the growing period scatter some salt over the ground which their roots occupy, it will find its way down to them; be careful not to give them an over-dose. If its appearance be unsightly, cover it a little; but it need not be buried deep, as it will be sure to find its way downwards. We have never weighed the quantity we use, but if the ground was scattered over about in the same way that weeds are destroyed in walks with the same material it will be ample—it is better to stop short of the quantity than overdo it. But if your trees show evident signs of going backward, examine and renew the soil, giving them fresh earth without manure, and we think by your description of it that it will be pretty good—a dry chalky soil is usually the most inimical to the Peach. Stiff loams, if not resting on stagnant water, are generally good; and the dark loams of many of the central counties produce excellent fruits.—J. R.]

WINTERING LILIUM LANCIFOLIUM.

RECENTLY you recommended the pots of this *Lilium* to be plunged in the borders all the winter. Would you advise me (situated as I am in the south, and not many hundred yards from the sea) to plunge my pots in the border (placing a piece of slate for the pots to stand upon)? Would you also advise me to cover with straw or litter?—J. BLACKLOCKE.

[Unless they were in the hands of first-class gardeners, the *Lilium lancifolium*, or what are called Japan Lilies, are far more safe out in the open borders of the garden, and if in pots, the plants should be plunged out of doors from November to March, in all parts of the British islands, including even the Orkneys, beyond the Pentland Firth. But very few in all these islands know how a bulb-pot, or a pot with any half-hardy, or any delicate-rooted plant, should be plunged, except he be a gardener, and a good gardener too.

To put a slate under a plunged pot in winter, or a piece of board, or anything, in fact, would be ruinous to a thousand kinds of plants. The right way is to open a small trench in an open part of the garden, and let it be just 4 inches deeper than the pot, or pots, and only as wide as the mouth of the pot, or a little wider. In the bottom of that trench, at one end, lay down two flat bricks, flat stones will do—so close that the pot is suspended between them—then the bottom of the pot hangs in the space between the supports, and no worm can get in, and the drainage, the main thing, is thus most perfect. Put in two more bricks or flat stones to support the next pot, and let the rim of it just touch the rim of the first pot. Do all your pot bulbs in that way, and the surface of the row, or rows of pots, to be just 1 inch lower than the rest of the ground. Only 1 inch, recollect. As long as the weather is mild leave them so, but when you know a change is coming draw a ridge of soil over the pots. The ridge should be 18 inches wide at bottom, or across the pots, and 9 inches high for the smallest size; but it may be a yard high, and twice that across the bottom, if one likes, and has materials to do it with. Old tan, or sifted cinder ashes, or sawdust, are just as good as the soil for the ridge. When the weather opens in the spring, open the ridge and see how they look, and put a couple of inches deep over the pots again, and they may remain there till the plants are in bloom.]

COCOA-NUT FIBRE REFUSE AND ITS USES.

I LIVE near a cocoa-nut mat manufactory made of yarn which is spun in India from the filaments of the outer coat of the husk, and I am told that none of the fibre is spun into yarn in England, or imported here.

In using the yarn for the matting there is some waste of the fibre from the friction, and also from cutting the surface of the yarn to obtain an even surface of the mats. These trimmings form a light mass of fibres about 2 inches to 3 inches in length, and the waste from the friction is of a more dusty nature.

Will you inform me if these are the articles referred to by Mr. Beaton as being so useful for mulching, and for growing Ferns in? Is it not likely to be a good thing for drainage over crocks, instead of moss?

I found it very useful in protecting the shoots of young Potatoes from the frost, by placing a handful over their tops when just coming above ground. It is so light and elastic that the shoots readily rise through it. I also used it round the roots

of Tea Roses against a wall covered over with cinder ashes, and I did not lose one of those Roses.—COCOIA FIBRE.

[The outer coat, or husk, of the shells of the cocoa-nut are pounded into dust like sawdust, in order to separate the fibres, just as the stalks of hemp and flax are done to obtain their fibre. That sawdust-like stuff is full of broken bits of the fibre, and that is what is good for Ferns, and Palms, and bulbs, and all bedding plants, and all plants for the kitchen pot, and also the best thing, perhaps, in Nature to bring alive and make to flourish old Orange trees and old Camellia trees that are already three-parts dead, to all of which we have had abundant proof. The mat makers, therefore, can have no cocoa-nut refuse, only the refuse of the cordage which is spun where the nuts grow. That refuse is the best of drainage stuff for pot plants, and with a little tuft of it over the hole there is no need of crocks at all. That stuff is also the best thing for plaster instead of hair; also, the best thing to put between a hotbed of dung and the soil, or leaf mould over it, and the very cords of which they make door, and passage, and tramp mats, is the very best and cheapest thing near large towns to support Scarlet Runners on. Against division walls put a row of nails 6 inches apart along the bottom of the wall, another row as high as you can reach, cut the cord to that length between the lower and upper nails, and run a length from nail to nail. Keep it dry in winter, and it will last seven years, perhaps fourteen years.—D. B.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE storing of all keeping roots to be completed. Trench and manure ground where any is vacant. Collect leaves for covering Sea-kale. *Artichokes*, immediate protection to be given to the roots, if not already done; in some situations it may be unnecessary, but it is best to be on the safe side. We have known a whole plantation to be destroyed by frost in what was considered to be a very favourable situation, and where it was thought quite unnecessary to protect them. *Cabbages*, all that are sufficiently advanced to admit of being earthed up should have it done before severe frost sets in. Red Cabbages for spring use may still be planted. *Cauliflowers*, those now producing heads are very valuable, therefore, the greatest care should be taken to preserve them from frost, either by digging them up and planting them in frames, or pulling them up and hanging them in a very cool shed. Protect from slugs the young plants under hand-lights or in frames. *Endive*, transplant as many as possible into frames where they may be at least protected from rain. Sudden frost succeeding the late heavy rains will more injuriously affect advancing salads than any other possible circumstances of weather. *Radishes*, these are sometimes required the year round; where this is the case, it will now be necessary to sow on a slight hotbed; after they are up, air to be given at every favourable opportunity. If they are sown immediately they will be ready to draw by the end of January. *Rhubarb*, a few old roots may be taken up, and planted in boxes or pots, which may be placed in a Mushroom or forcing-house, where the heat is about 60°. *Small Salad*, keep up a succession by sowing in boxes about twice a-week.

FLOWER GARDEN.

Where the principal part of the flower-beds are now empty, let them be well turned up to the bottom, and if much exhausted the application of a good dressing of leaf mould will be found the most suitable restorative for this department. The introduction here of strong manures has generally a tendency to do more harm than good by causing an over-luxuriance highly unfavourable to the production of bloom. Protect the roots of the Tea and Perpetual Roses and Fuchsias with a coat of wood ashes. The Roses and half-hardy climbers against walls to be pruned and nailed before being covered up; but while the weather continues mild, the longer they are exposed the better. The planting of bulbs of all kinds, if not already done, should now be finished as soon as possible. The planting of all kinds of hardy trees and shrubs may now be advantageously proceeded with. Grass lawns and gravel walks to be constantly attended to, or otherwise they will soon become unsightly. Take up the Dahlias as soon as the tops are frosted; do not clean too much soil from them, it will prove a protection when dry.

FRUIT GARDEN.

It is now a good time to take up and root-prune such trees

as are growing too luxuriantly to wood without producing fruit. Let a wide and deep trench be opened at a proper distance from the stem, so that a man can work with freedom standing on a level with the lower roots, he will then find less difficulty in undermining the tree. As the smaller roots are cleared, they should be tied in bundles to the larger to prevent their being bruised, and to be out of the way of the workman. When the tree is taken up the large perpendicular and bruised portions of any others to be cut clean off. Replant as soon as possible. Raspberry plantations may be cleared of the dead canes and superfluous wood; the suckers to be taken off, and, where required, the strongest to be at once planted for succession. Fig trees to have some dry fern or spruce boughs nailed over them to prevent injury from severe frost; though this is less likely to occur this season than any we remember, as, from the fine light and warm summer we have had, the wood of every description of trees is well ripened, and, consequently, will resist the effects of severe weather with greater impunity; whereas, if ill-matured, it would suffer severely. If we may venture to predict, we should say that next season would be more than usually abundant in fruit of all sorts.

STOVE.

Let such of the Orchids as have completed a good season's growth, and which are somewhat inclined to be deciduous, sink gradually into repose. Those evergreen kinds, as some of the *Dendrobiums*, the *Ærides*, *Saccolabiums*, *Vandas*, &c., on blocks or in baskets to be loosened a little from the roof, if too near, in order the better to escape the vicissitudes of temperature to which that situation would expose them in winter.

GREENHOUSE AND CONSERVATORY.

Look regularly over the plants, and remove all decayed and decaying leaves, and keep everything sweet and clean. Watering to be given with care, they should have no more moisture supplied from the watering-pot than is sufficient to keep them from flagging. If the house is free from damp, no artificial heat will be required until danger from frost is actually apprehended; but take care that the heating apparatus is in such order that it can be instantly used, as the necessity for it may be daily expected.

FORCING-PIT.

Keep up the supply of all kinds of bulbs and the usual shrubs, and other plants required for winter decoration.

PITS AND FRAMES.

All plants intended to be wintered in these structures to be finally arranged as soon as possible. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

We had a heavy fall of snow on the 2nd, and a sharpish frost on the evening of the 3rd, and morning of the 4th, which has rather impaired the beauty of all this ornamental. Had not thrown earth round the stems of Dahlias many days too soon. As soon as the snow was over on the 2nd, whipped up all the Cauliflowers at all forward, and secured them in a shed. Turned over on their sides a bed of young Cauliflowers just beginning to show in an earth pit, and brought all others beginning to button and put them with good roots in the same place, where protection can be given them. Put straw ready to cover *Radishes* outside on a bank, and made up a bed of litter and leaves, and sowed the first bed that will have heat to assist them. The bed was about 24 inches high at back, and 18 inches in front, and would not produce much heat as the materials had been previously used; but the height of the frame would permit of a good lining of dung, and leaves being put against it in winter when the *Radishes* might need a little to make them crisp and short; the *Radish* being one of the few things that are generally better when forced than when grown in the open air. Protected the Dwarf Kidney Beans in turf pit, still bearing nicely, and removed those in pots into a pit where a little fire heat could be given to them. Regulated Cucumbers, which we intend to keep a little longer for a party, and then, most likely, will destroy them, as we find that hardly any visitors will look at them in winter. Took up some Lettuces fit for use, and placed them under glass protection in an earth pit. Put slates and tiles over *Endive* to blanch them, and would have taken means to protect them too, but the frost

is all gone, and plenty of deluging rains have come instead. Swept over Mushroom-beds with a hair-broom, and sprinkled the surface with a little fresh hay, and have generally plenty, though the fine dried horse-droppings form a small part of our dung compost—in fact, I use almost anything to give a little heat to start with, and use horse-dung chiefly for surfacing, to insure the spawn in.

FRUIT GARDEN.

Our *Strawberry-pots* are still partly out. The little nip of frost will do them good as helping to check growth, and part have now been put under protection, and the rest will be secured from heavy wet and frost as soon as possible. We will either sink the pots or pack them close together in leaves so as to defend the pots from the frost; and the tops can also be secured, though a few degrees there will do less harm than having the pots exposed. The pots have been standing on a hard gravel, with tar underneath, and so little water have they had of late that the roots have been running quite freely along the surface of the gravel, and some of the pots required a gentle pull to take them up. The roots thus nipped off will not injure the plants; but, had I thought of it, the pots would have had a twist round three weeks ago, and most likely every week since. This would, perhaps, have tended to ripen the buds even better, though I have no reason to find fault with them. A correspondent says in reference to a practice detailed the other week, "Do you then prefer plunging *Strawberry-pots* at all times that are intended for forcing?" And I reply, No! I only prefer keeping the pots from frosts in winter. In summer I prefer the pots to be exposed somewhat, and to stand on a hard bottom; and, even in early forcing, I either prefer the pots to stand exposed on a hard bottom, or, if plunged at all, that the bottom of the pot should be on a hard surface, as a board or slate.

Ran the hoe through *Strawberry-quarters* that the rain night sink in when it came. Repotted some Peaches, &c., into larger pots. Would have done it earlier if I had had the pots, but as they still retain some leaves, and as the pots were three-parts plunged in the ground, and will be covered all over with litter, hope the roots will keep growing away all the winter, so that the buds will receive no check in spring from the late repotting. The shift was not a large one, the fibres were disintegrated a little at the sides, the plant being well watered previously and the new soil rammed in as hard as possible, and left a little higher than the old ball in the centre. Being thus plunged and covered over with litter, and protected in a glass case no more water will be needed until the buds move in the spring. Plunged and treated others not fresh-potted in the same manner until we can find time to top-dress them well. Vines in pots the same, and being put as close as they would stand comfortably, we shall thus secure room for Strawberries and other things, where they can be kept dry. Looked over Vines, the houses being flat, some kinds are apt to damp with all the air that can be given to them, and one bad berry soon makes other two or three bad. A steep roof is the one for late Grapes. If well glazed, moisture dropping from condensation is next to impossible. Stripped off lots of Fig leaves to give light to Geraniums, &c., placed below, as the Figs still refuse to give over ripening, though a few days' dull weather would render them not worth eating. Pruned front part of Peach-house, washed and painted the wood with a paint of clay, cowdung, and sulphur; forked up the border, and filled the space with boxes of variegated Geraniums, just struck, in order to have them where covering-up could be avoided, and anything like damping be prevented.

Pine-pits were also cleaned and regulated, and filled with plants in the meantime; and late cuttings not quite forward enough, were brought from cold pits and placed in pits where a little bottom heat could be given, and air at pleasure, by just giving a little fire heat. These movings will enable us to have room in cold frames and earth pits for young Cauldowers, Lettuces, &c., and give some space, i.e., for similar things in an orchard-house. The old *Geraniums*, &c., stuffed in sheds, of course, escaped all the frost; and as we have no rough boxes at hand, as time permits we keep stripping them of the short points of their shoots and all the leaves, and stuffing from twelve to twenty-four of them into an eight or twelve-inch pot, filling up three-parts with common soil, watering well, allowing them to settle, and then placing 2 inches or 3 inches of dry soil on the surface, and then placing them below stages, in sheds, anywhere and everywhere, so that neither frost nor damp to any great extent will reach them.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

SKELTONISING LEAVES (A Subscriber).—We do not know the mode of skeltonising leaves in a quarter of an hour; and if we did we should not think our best just to publish the mode, as the discoverer offers to impart it to any one for 5s., and to which he is fully entitled.

COAL ASHES ON GRASS LAND (H.).—If the soil is a strong loam, clayey or wet, the coal ashes will be of benefit; but if the soil is light and dry they will do more harm than good. If the Clovers and Trefoils do not grow well in your meadow this may arise from a deficiency of sulphate of lime (gypsum) in the soil, and in this case a slight addition of the ashes to your early compost would be beneficial, for such ashes always contain sulphate of lime.

COCA-SIT FIBRE LEIFTS (Mary).—If you know any one who will take a sack to the Kingston manufactory, fill it, direct it, and take it to the railway station, you may have the sack full gratis. You had better, as you live in Lancashire, inquire at Liverpool or Manchester for a cocoa-sit fibre matting manufactory, you can obtain it there, or at any other such manufactory, as readily as at Kingston.

MUSHROOMS GROWING UNDER A CONSERVATORY (H. B.).—Your plan and description seem both good, and we should say there is no doubt that you will be successful. One thing, however, is almost needless—that is, a circulation of air underneath the beds. Mushrooms, like every other fungus, grow best with a confined rather than an ever-changing atmosphere; and we think that, with your height of bed, one foot or two shelves might be fitted up, and allow the bottom bed to be on the ground. Slate is an excellent material for shelves, and we hope the roof of your Mushroom-house (or room) is arched brick or stonework, and not timber, as neither tends to destroy timber, as that the refined air and warmth of a Mushroom-bell. You will however see some other shelves, one or two, and you may depend on the practical character of such communications, but so much depends on the materials used and other circumstances, that a failure is not always a condemnation of the means used.

KEEPING FOWS DAMP IN A PIT (O. Price).—Cover the bottom of the place, and cover it with dry rough ashes, and give air all favourable opportunities, and you will not have any trouble.

FLOWER-LEDS (A. G. Linn).—We uniformly refuse to advise how beds should either be sown or planted. We only point out what is wrong in the planting and sowing submitted to us.

WALTONIAN CASE (G. S.).—There is not a man in your whole county who can make a Waltonian proper, except one man, the original maker, one of Mr. West's workmen, who he instructed. Scores of people have made the article, but have been in America, but to no purpose. One of our friends in New York spent £15 on it and failed, and after that had to buy one from Mr. West. Mr. Jones, on Sutton Hill, who is in the same line of business as Mr. West, and who had full access to Mr. West's workshops and stores, made many of them, and advertised them in cheaper than his next-door friend, but they failed. Mr. Weston assures us the "works" inside these Cases are ingenious as the work of the clockmaker. He also tells us that it is a point of trust in him never to describe the making of a Case, and no one else can describe it save Mr. West himself and his maker. And all our descriptions of it go no further than the drawings which accompany the advertisement.

PLANT TRIES ON A SMALL SPACE (Inquirer).—Take a heavy crop if you can get it, and that you do not do it, if that does not do it sufficiently, cut the roots in summer whenever you find the shoots getting too strong; keep the shoots equal size by distubbing and stepping back to 1 inch or 2 inches any shoots that appear too strong; that is one way. Another is, suppose that you have as many leading young shoots as you want, lay them in regularly, and give every lead to start next season, and all the well-placed ones retain; and instead of allowing young shoots to grow on, stop them if they have made three or four leaves, stop again when a couple or three leaves are formed, and thus you will have the shoots covered over with strong. A little top-dressing of litig. these plants, and remaining them every other year, will make them fruitful and bounteous growers.

APPLES AND PEARS FOR AN ESTABLISHED RAISING (Ideo).—APPLES.—Adams' Pearmain, Cellin, Cornish Gillyflower. PEARS.—Louise Bonne of Jersey, Knight's Monarch, Williams' Bénédictine.

FLOWERING HARDY PLANTS FOR TILLANS (Jolin).—Plants of the *Jasminum nudiflorum*, though yielding no scent, would look beautiful with their yellow flowers in winter and spring. Roses would also be beautiful in summer, and the double white Clematis would be splendid and almost sweet in autumn. We might fix on a hundred plants, but hardly anything would beat the Clematis, especially if there was an arch over the gate.

STRIKING PLAINS (A. L. J.).—The best way of striking and growing Ferns is too wide a question, and includes a dozen other questions. What kind of Ferns do you mean? Say which, and we can soon answer you in full. The easiest refuse question is answered in a reply to another correspondent to-day.

DISTURBING MOSS ON FRUIT TREES (Ector).—Painting the stems with a creamy mixture of quicklime, and soot added to subdue the offensive whiteness; or scrubbing the stems with a hard scrubbing-brush dipped in a strong brine of common salt, are effective applications.

COLO-TIT (Uplua).—We will give a copious answer with some illustrations next week.

INSE BETWEEN NURSERYMEN AND LANDLORD (Ten-year's Subscriber's).—We are surprised that any one should venture to plant trees, &c., on another man's land, with no other written title to the tenancy than the worse than worthless scrap of unstamped writing of which you send us a copy. It is worse than worthless, because, if it is at all binding, it empowers your landlord to give you notice on the 1st of next December to quit at the end of six months, in the very worst period a nurseryman can quit. We cannot advise you how to act if your landlord is unreasonably; but if you both act rationally, the best course to pursue will be to have a friendly arrangement for you to quit at a season more favourable to the nurseryman of nearly 500*l.* The thing can be arranged at any time upon paying a fixed penalty.

LAPAGERIA ROSA CULTURE (C. K.).—We find that No. 573 out of print, so we condense for it the following. For the first three or four years of good growth *Lapageria* may be grown in a pot as well as in a border, as some extra heat can be thus given it for two or three months in the spring, as we have reported from the nurseries. The plant should not be watered during the circumstances later than the middle of August, nor be kept in artificial heat later than the middle or end of September. In ordinary cases, however, this plant ought not to receive artificial heat after the summer sets in warm enough to dispense with fires in stoves and drawing-rooms. Keep the frost from it in winter, and all the end of February introduce it into stove heat, if there is a stove; and, after 6 inches of fresh growth are made in heat, put it afresh, if it require it, and keep it in this heat till the end of May, by which you will gain two more months to the summer as it were. A north rafter in a conservatory-house will suit it best; but as to pole, pillar, trellis, or chains, they are all the same to all climbers. As to the size of the pot or pan, that depends entirely on the quantity of roots. Once it is fairly in good growth, *Lapageria* rosa requires an enormous deal of water—say four times more than a Passion-Flower. When three or four years old it should be planted in the greenhouse or conservatory-border.

NAMES OF FRUITS (J. F.).—APPLES.—No. 1, Cambridgeshire Pippin; 2, Dumelow's Seedling; 3, Court-pendu Flat; 4, Pearson's Plate; PEARS.—No. 1, Winter Nells; 2, Crispin; 3, Beurré d'Angoulême; 4, Passe Colmar. (H. L. L.).—No. 1, is a bird specimen of Duchesse d'Angoulême; 2, Napoleon; 3, Winter Nells; 4, Beurré d'Angoulême; 5, Thompson's; 6, Black Worcester. (Deron).—No. 1, Boston Russet; 2, Gloria Mundi; 3, Hicks' Fancy; or more properly Early Nonpareil. (S. G. G.).—Your Apple which is so beautifully striped and with a bloom to it is Henry Young's. The green one is Bedfordshire Boulding. (Clericus).—No. 1, Verulam Pear, or, as it used to be called, Buchanan's Spring Beurré—it is only a stewing Pear; 2, Beurré d'Espérance; 3, Passe Colmar; 4, Duchesse d'Angoulême; 5, Beurré d'Angoulême; 6, Beurré Rose; 7, Knight's Monarch. (A. S. G.).—We have mercy on you. How do you think we can find time to examine and name about three dozen Pears and more than half as many Apples? You must wait. (Adam, Jun.).—It is the fruit of *Passiflora edulis*. You may still plant Roses in the open ground.

NAMES OF PLANTS (Z. K.).—*Taxodium distichum* and *Ehmannia alternata* multicaulis. (J. D.).—Very imperfect stampings. They appear to be: 1, *Matricaria chamomilla*; 2, *Geranium psillium*; 3, *Scabiosa succisa*; 4, *Gaillium parisiense*.

FLOWER SHOWS FOR 1861.

NOVEMBER 12th and 13th. STOKES NEWINGTON CHRYSANTHEMUM SOCIETY. Sec., W. T. Howe.
NOVEMBER 14th and 15th. CRYSTAL PALACE. (CHRYSANTHEMUM SHOW.) Sec., W. Houghton.
N.B.—Secretaries of Societies intending to advertise in our columns will oblige us by sending an early intimation of their exhibition days.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

WHO MAY WIN AT BIRMINGHAM AND THE CRYSTAL PALACE SHOWS.

A SHORT TIME since it was our duty to warn our friends and readers that it was time to make their entries if they intended to be among those who achieve the great distinctions, and secure (if they wish to do so) the substantial profits of the great prizes at Birmingham and the Crystal Palace. For many years at this period we reiterate old instructions to our subscribers, and ask ourselves whether our efforts are not "tedious as a three-fold tale." We need not, however, wait for an answer. The queries we receive, and the advice that is asked, prove to us either that the knowledge is laid aside till wanted and is not then to be found, or that it is altogether forgotten, or that there is always a new class springing up, and that if every new subscriber buys our back Numbers he does not of necessity read them.

The art and practice of prophesy have of late taken a start in the racing world. The prophets, like fortune-tellers, make stock of their success, and sink their failures in the waters of Lethe; or, seeing we are just now on our classical stilts, we will say that many of the modern prophecies are like the ancient oracles, and will bear such interpretation as may be desired even by adverse parties. These are at best but titubant days; all things have their money price, and "re-racing" the future will be invaded and forestalled, and the events of next month positively described in return for thirteen postage stamps enclosed to "E. F.," care of Tom Saunders, *Pegasus* Office, White Horse Lane.

We are very glad no such efforts are required of us. We can tell Sempronius "That not in mortals to command success," but we can also teach him to do more—we can teach him to deserve it. Perhaps that requires qualification. We can, then, tell him what to avoid; we can lay down a chart in which all the rocks and quicksands on which many have made shipwreck of their success will be plainly marked. To our work, then.

SPANISH.—Perfectly upright comb for the cock, falling over for the hens. Thoroughly white faces, without mixture of red. Perfectly black plumage. Size desirable, not essential.

DOEKINGS.—Size essential. Combs immaterial; but alike in all the birds composing the pen. White legs, and good distinct five claws. It is well to observe that, although it is desirable, it is not absolutely necessary the extra claws should be long ones. Disqualification cannot follow where there are five; but two nails on one claw are not sufficient. In the Coloured Dorking classes there is no fixed or settled colour; but, at the same time, there must be no startling incongruity or offensive contrast. It must always be borne in mind the competition at these great shows is very great, and at times so close that a trifle will turn the scale. In these, as in all white-legged fowls, it is well to send them to an exhibition clean, and a flannel, with a little warm water and soap, will remove all superficial dirt.

COCHIN-CHINAS.—Large size very desirable, but not sufficiently important to hide defects. Straight and upright combs, sharp heads, well-clipped wings, ample tuft, and well-feathered legs necessary to success. In the Grouse and Partridge varieties, the cocks must have black breasts, and the less yellow tinge there is in the hens or pullets, the better it will be for their chance of success. The white variety must have yellow legs.

In the GAME you must have sharp and intelligent heads, close plumage, straight combs for the hens, absolute matching in colour, flat feet, short thighs, faultlessly straight breast-bones, and high condition. The exhibitor in these classes must be very careful that his birds agree, and the appearance of concolor for a few hours is not enough. The neglect of this precaution causes numbers of disqualified pens, because a cock and hen or pullet cannot compete where two are necessary; and when Game fowls disagree, cannibalism begins at once. It is a natural but a sorry consequence to find a prize lost and a good bird spoiled for want of painstaking.

Show your POLANDS honestly. Do not seek to improve the black with white top-knots by trimming away any black feathers there may be in front of the top-knot. Choose your hens of this breed with close, compact top-knots. In this class only of Poland's may the cock have comb, gills, or spikes. Golden and Silver Poland's must have spangled breasts, laced and barred wings, and the hens must be spangled all over. In the Silver all the tails in the pen should be purely white, tipped with black. The cocks should have clouded hackle and saddle, and they are disqualified if they have either comb, gills, or spikes. It is important you should carefully examine the backs of all the birds of this breed you send to exhibitions, as they are very prone to be crooked and hump-backed. *Either will disqualify.*

PENCILLED HAMBURGHS should have accurately-marked plumage, the ground colour being yellow or white as may be; every feather taken separately should present from eight to twelve markings, or from four to six stripes. The conjunction of these forms the penciling. They must, therefore, be well-defined. If they run into patches, they are mossy; if they are too small they become spots, and, failing to join, they do not form pencilling—both are *very serious* defects. The tail-feathers should be pencilled to the point. The hackles should be spottish; but it is difficult to accomplish this. In both cocks and hens, the comb must be very bright, full of points, spiked behind, the spike turning upwards. These combs must be firm on the head. Any falling over, or obliquity, are disqualifications. (To be concluded next week.)

"WHO BOUGHT MY PEN OF FOWLS?"

I READ in your last a letter from Mr. Musgrove respecting who bought his pen of fowls at the last Crystal Palace Show. Now, as the present owner of the birds, your reply to him is all that I think is required, and I only have to say that if the Crystal Palace authorities permit the names to be given up of persons claiming poultry, it will prevent many from doing so.

We all have our "hobbies." I have one for poultry, and, as Mrs. Blair says, "I ride it;" and to indulge this hobby I may give more for a pen of birds than I reasonably ought to do, and

at the same time do not wish all the world to know it. Besides, I can see no good by its being known. At any rate, if the Crystal Palace authorities do so, they will have no more to per cent. commissions to deduct from sales of birds to me. And as to publishing the breeder's name, it is well known Mr. Musgrave claimed a pen of Buff or Cinnamon Cochins at the last Crystal Palace Show for £20, and he exhibited them again at Worcester in the expectation of winning the vase; but did he say they were not bred by him in the catalogue at Worcester? No! Then let him not find fault with others when he sets such a bad example himself; and, as Mr. Musgrave appears so anxious to know who claimed his pen, I can only say he can meet the owner in person at Birmingham Show (perhaps somewhere near the first prize Partridge Cochins pen chickens of 1861), when he will afford him every satisfaction he may require; but as to Mr. Musgrave fearing buying back the same strain, falsely or otherwise, he may rest assured he will never have a chance, at least not if it is known to—A YOUNG COCHIN COCK.

DEVIZES POULTRY SHOW.

This Show of poultry proved to be one of the best that has taken place during the present year. The competition was of a very close character, and embraced not only well-known exhibitors from all parts of England, but even the sister Isle was represented by poultry that would well add to the high character of any similar meeting. Perhaps one of the most confirmatory proofs we can adduce in support of the statement just made is the fact that in an entry of 331 pens, a favourable notice from the Judge in the prize list will be found to no less than 181 pens—a circumstance in any local show almost without precedent. It will perhaps be well here to mention that by the predetermined arrangement of the Devizes Committee, "Very Highly Commended" cards were appointed for those especial pens that ran more closely than ordinary in the wake of the actual prize-takers. That such a provision adds most materially to the difficulty and general labours of an arbitrator will, even at first sight, be obvious to any of our readers; and indeed so much so that in very large entries, such, to wit, as those of Birmingham and the Crystal Palace, it would be impracticable to carry it out; still, in a comparatively small show, at which not unfrequently the competition is so complicated in point of numbers for priority of position between the lowest premiums and those pens enjoying the simple honour of a high commendation, this plan appears not unreasonable. In this place, a little item might be favourably alluded to, rather more interesting to the committees of poultry shows and the appointed arbitrators than the exhibitors themselves—viz., the introduction of a schedule of the premiums offered, bound up as a first page of the Judges' books, so that those gentlemen can at once refer to every condition, without either the loss of time or unavoidable mistakes that sometimes arise from not having the printed regulations at close hand during the very time when, of all others, their consultation is the most important.

With praiseworthy precaution to avoid any errors arising, and to be also able to speak personally to the actual condition of every pen on its arrival, the toilsome task of unpacking every lot of poultry was self-assigned to one of the Honorary Secretaries—Mr. Saunders Sansbury, which, together with the re-packing by the same individual, was efficiently fulfilled. We feel gratified in being able to state the fact that among all the poultry received, only one death had arisen during transit—that of a Mandarin Duck that had actually travelled from Dublin for competition. The policy of sending this description of fancy birds so long and precarious a journey admits of some doubt, as, on account of not being so thoroughly domesticated in their habits as common poultry, any little hardship tests their endurance most materially, and sudden changes of any kind not infrequently produce uncontrollable frights of a serious character. The Duck, when received, appeared to have been dead for several hours. The drake looked as well as ever, and was one of the most perfect and high-coloured specimens we ever saw. Without a wish to belong to those who ape the sentimental, we cannot forbear to allude to a circumstance that really deserves it. The dead Duck was taken out of the basket, for the inspection of the arbitrator, when its beauteous mate at once recognised it, calling plaintively and opening its wings, as though anxious for its recovery. Directly it was removed, which was without delay, the drake became as placid and reconciled as

before. It will be seen by reference to the prize list that an extra bonus of 10s. was allotted to this pen.

The *Spanish class* was a peculiarly good one. The hens in the first-prize lot were unusually excellent; but this pen yet wants another month to be in first-rate feather. They belonged to Mr. Martin, of Chaires, Worcester. It is almost superfluous to say that the second and third-prize pens, both of Mr. Rodbard's stock, were also excellent. Several of the highly commended pens were also well worthy of praise.

The *Grey Dorking* class was first-rate, Lady Julia Cornwallis taking both the principal prizes, and Lady Louisa Thynne proving a very close run, as a third. Nearly every pen in this class, and also the White Dorkings, was far better than customary. In White ones it will be seen the Rev. G. F. Hodson and Mrs. Beauchamp took relative positions.

In the *Game* classes, the birds, as we anticipated, were barely as yet recovered from moulting, but most of them were truly good specimens. In these classes, Mr. Fletcher of Stoneclough, Manchester, monopolised a full lion's share. The whole of this gentleman's exhibited stock showed very excellent management, and no doubt we shall hear of most of them in other prize lists. The condition of Mr. Dawson's birds is well worthy of mention also.

In *Bull Cochins*, Mrs. Fookes swept the deck of all prizes, as did Mr. Cartwright in the Partridge-coloured variety. It is really a great pity that Mr. Cartwright's first-prize cock is moulting mealy in the tail-feathers, being in a lot other respects a pen only rarely equalled. In White Cochins, that well-known exhibitor, Mr. Titterton, of Birmingham, took precedence, but his fowls were exhibited in sad plumage, though first-rate specimens. It is a mistake to injure them by long journeys and close confinement in their present lack of plumage.

It is the old cry to say Mr. Ballance won the principal *Malay* prizes with capital birds and well shown. Of *Hamburghs*, decidedly the best breed were the Silver-spangled ones. Mr. Joshua's first-prize pen were about as faultless a group as we can call to recollection. The Silver-pencilled were remarkably good. The *Black Falds* were gems, but still want a week or two to bring them into complete feather. The *Brahmas* were a very numerous and good class. In *Bantams*, the Game and Sebrights were the most commendable, though all these classes were good throughout, as may also be said of the *Ducks*, *Turkeys*, and *Geese*, generally. The East Indian Ducks were a large and unusually perfect class, the Hon. Sec. holding his own against all opponents. The extra varieties of poultry were both novel and well shown. The attendance of visitors was beyond anticipation, and the Show passed off successfully.

SPANISH.—First, J. Martin, Mildenhall Mill, Claires, Worcester. Second and Third, J. R. Rodbard, Aldwick Court, Winton, Bristol. Highly Commended, J. O. Drinkwater, Coal Wharf, Colne; V. Sandford, Chatsworth Lodge, Manchester, Plymouth. Commended, A. Hale, Colne.

DORKINGS (Coloured).—First and Second, Lady J. Cornwallis, Linton Park, Staplehurst. Third, Lady L. Thynne, Moulton Court, Worthing. Very Highly Commended, Lady J. Cornwallis; Lady L. Thynne; Marquis of Bath, Longlet, Warrminster. Highly Commended, Rev. J. G. A. Baker, Old Warden, Higgonsdale, Devizes; J. W. Joshua, Perrot's Brook, Cirencester. Commended, G. Hanks, Quobwell Farm, Malmesbury; R. W. Boyle, Rosemount, Dublin; Marquis of Bath.

DORKINGS (White).—First, Rev. G. F. Hodson, North Petherton, Bridgewater. Second, Mrs. Beauchamp, Uphams, Fureham, Hants. Highly Commended, Mrs. Fookes, Whitechurch, Blandford. Second, G. Stone (Black-breasted and other Reds).—First and Second, J. Fletcher, Stoneclough, near Manchester. Third, V. Sandford, Chatsworth Lodge, Marnock, Plymouth. Very Highly Commended, E. Archer, Malvern; W. Dawson, Sec. Oak, Birmingham; R. Elting, Sutton Parva, Warrminster. Highly Commended, J. Keeble, Bathampton, Newbury. Commended, Rev. G. S. Crawley, Crows Orchard Court, Tiverton.

GAME (Duckings and other Greys and Blues).—First, J. Fletcher, Stoneclough, near Manchester. Second, W. Dawson, Selly Oak, Birmingham. Third, A. M. Soper, Secord. **GAME (any other variety).**—First, W. Dawson, Selly Oak, Birmingham (Black). Second, T. Burgess, jun., Burleydam, Whitechurch, Salop (Black). Third, J. Fletcher, Stoneclough, near Manchester (Black). Commended, T. Wilkinson, Newgate, Holmforth, Huddersfield (White).

COCHIN-CHINA (Brown and Partridge-feathered).—First and Second, P. Cartwright, Oswestry. Commended, Mrs. H. Fookes, Whitechurch, Blandford. Mrs. V. Musgrave, West Tower, Newbury. **COCHIN-CHINA (any other variety).**—First, G. R. Titterton, Metcalley Abbey, Harborne, Birmingham (White). Second, G. C. Whitwell, Kendal (White). Highly Commended, E. Pigeon, Lymington, Exeter (Black). Very Highly Commended, C. Ballance, Secord.

MALAYS.—Prize, C. Ballance, 5, Mount Terrace, Taunton, Somerset. Very Highly Commended, C. Ballance. **HAMBURGHS (Golden-pencilled).**—First, J. Munn, Heath Hill, Stackstead, Manchester. Second, A. Nuttall, Newchurch, Manchester. Highly Commended, A. Nuttall.

HAMBURGHS (Silver-pencilled).—First, J. Martin, Mildenhall Mill,

Claines, Worcester. Second, J. Mann, Heath Hill, Stuck-steds, Manchester. Highly Commended, Master E. E. Keable, Maddell Farm, Lambourne, Berks.

HAMBURGUS (Golden-spangled).—First, J. Dixon, Bradford, Yorkshire. Second, W. R. Lane, Bristol Road, Birmingham. Highly Commended, Messrs. Reynolds & Aldwell, Northidge, Holkath, Yorkshire; L. Wiltshire, Police Station, Calne. Commended, F. Baily, Calne.

HAMBURGUS (Silver-spangled).—First, W. Joshua, Perrott's Brook, Cirencester. Second, Lady J. Cornwallis, Linton Park, Staplehurst. Highly Commended, Lady J. Cornwallis; J. Martin, Middenham Mill, Claines, Worcester.

POLANUS (Black with White Crests).—First, G. Ray, Ivy Cottage, Minestead, Hants. Second, T. P. Edwards, Lyndhurst, Hants. Highly Commended, J. Dixon, Bradford, Yorkshire. Commended, Messrs. Pepworth and Coldwell, Northidge, Holkath, Yorkshire.

POLES (Gold).—First, J. Dixon, Bradford, Yorks. Second, Mrs. Pettat, Ash Rectory, Overton, Hants.

POLANUS (Silver).—First, J. Dixon, Bradford, Yorks. Second, withheld. **BRABMA POOTRA.**—First, J. H. Craigie, Woodlands, Chigwell, Essex. Second, Lady L. Thynne, Muntham Court, Worthing. Very Highly Commended, A. Heath, Calne. Highly Commended, J. K. Fowler, Prefendal Farm, Aylesbury; J. H. Craigie.

BANTAMS (Gosh).—First, T. H. D. Bayly, Ickwell House, Biggleswade, Beds. Second, D. Nicholson, Farnham, Surrey. Highly Commended, V. Sandford, Chatsworth Lodge, Manna-mead; R. W. Boyle, Rosemount, Dublin; Miss V. W. Murgrove, West Tower, Aughton, Ormskirk. Highly Commended, Mrs. Beardmore, Uplands, Farnham, Hants; H. Adley, Lympstone, Devon; M. Leno, jun., the Pheasantry, Markgate Street, Ferts.; L. Nicholson, Northleigh, Plymouth. Commended, W. R. Lane, Bristol Road, Birmingham.

BANTAMS (Gold and Silver-laced).—First, M. Leno, jun., the Pheasantry, Markgate Street, Ferts. Second, T. H. D. Bayly, Ickwell House, Biggleswade, Beds. Very Highly Commended, Rev. G. S. Sainsbury, Craws Mill, Cambridge. Commended, Rev. G. E. Hodson, North Petherton, Bridgewater (Gold); Miss G. Everett, Gibraltar Cottage, Monmouth (Silver); Lady L. Thynne, Muntham Court, Worthing (Gold); Rev. G. S. Cruwys.

BANTAMS (any other variety).—First, Mr. F. Hutton, Garden House, Padesy, Leeds (Black). Second, T. H. D. Bayly, Ickwell House, Biggleswade, Beds (White). Highly Commended, Bev G. F. Hodson, North Petherton, Bridgewater (Black); V. Sandford, Chatsworth Lodge, Manna-mead (White).

ANY OTHER DISTINCT OR CROSS-BREED NOT MENTIONED.—First, E. Hutton, Garden House, Padesy, Leeds (Black Hamburgs). Second, Miss M. Ewart Broadleaze, Devizes (Silk Fowl). Very Highly Commended, Lady L. Thynne (Silkies) Highly Commended, H. Jennings, jun., Virginia Water (Phasant Fowls); E. Pigeon, Lympstone, Exeter (Crève Coeur); R. H. Nicholls, Malpas, Newport, Monmouth (Silkies); Commended, A. Bawn, Longestreet, Ferts.

GENS.—First, Marchioness of Winchester, Anport St. Mary's, Andover (Tonlouse). Second, Mrs. H. Pookes, Whitechurch, Blandford. Very Highly Commended, R. W. Borle, Rose Mount, Ludlin (Tonlouse); H. Brown, Blacklands Park, Calne (Tonlouse); Highly Commended, Marchioness of Winchester (Tonlouse); Lady L. Thynne.

TREKES.—First, Miss L. Crawshaw, Caversham Park, Reading (Cambridge). Second, Marchioness of Winchester (Cambridge). Very Highly Commended, Mrs. H. Pookes, Whitechurch, Blandford; Miss J. Milward, Newton St. Loe, Bath.

DUCKS (Aylesbury).—First and Second, J. K. Fowler, Prefendal Farm, Aylesbury. Very Highly Commended, G. Hanks, Quoibell Farm, Malmesbury. Highly Commended, G. Briant, jun., Littlecott Mills, Pewsey; G. Hanks; J. O. Brickwork, Calne.

DUCKS (Roman).—First, J. K. Fowler, Prefendal Farm, Aylesbury. Second, J. Holme, Knowley, Prescot. Very Highly Commended, W. Joshua, Perrott's Brook, Cirencester. Highly Commended, Marchioness of Winchester; Rev. H. G. Baily, Swindon; W. Locke, Cleeve House, Seend, Melksham. Commended, W. R. Elliott, 5, Windsor Villas, Plymouth; Lady L. Thynne.

DUCKS (Black East Indian).—First and Second, G. S. Sainsbury, Rowle, Devizes. Very Highly Commended, G. S. Sainsbury; Mrs. Beardmore, Uplands, Farnham, Hants; J. Martin, Claines, Worcester. Highly Commended, G. S. Sainsbury. Commended, Mrs. Jenner, Netheravon; G. S. Sainsbury.

DUCKS (any other variety).—First, J. Dixon, Bradford, Yorks (Mandarins). Second, T. H. D. Bayly, Ickwell House, Biggleswade, Beds (Grey Calls). Extra Prize, R. W. Boyle, Rose Mount, Dublin (Mandarin). Very Highly Commended, Marchioness of Winchester (White Egg); W. Locke, Cleeve House, Seend, Melksham (White Call); W. Joshua, Perrott's Brook, Cirencester (Wild); Commended, E. Huton, Leeds (Wild).

GAMC COCKS (any colour).—First and Second, J. Fletcher, Manchester. Third, T. Burgess, jun., Burleydam, Whitechurch, Salop. Highly Commended, Rev. G. S. Sainsbury, Cleeve Moorhead Court, Tiverton.

GAMC COCKERS (any colour).—First, J. Keable, Thurston, Newbury. Second, Rev. C. E. Ellis, Sutton Parva, Warrminster. Third, E. Archer, Malvern. Commended, J. Fletcher, Stoneclogh, Manchester; T. Burgess, jun., Burleydam, Whitechurch, Salop.

GAMC BANTAM COCKS.—First, W. S. Forrest, Eagle Cliff, Greenhithe, Kent. T. H. D. Bayly, Ickwell House, Biggleswade, Beds. Miss E. A. Crawford, Southwell. Highly Commended, T. H. D. Bayly; Miss V. W. Murgrove, West Tower, Aughton, Ormskirk. Commended, T. Burgess, jun., Burleydam, Whitechurch, Salop; O. Nicholson, Farnham; R. Moon, Sandford Lodge, Waverley, Liverpool.

SPRING COCKS.—Prize, J. R. Godhard, Alwick Court, Wrington, Bristol. Highly Commended, J. O. Brinkworth, Coal Wharf, Calne.

DORKING COCKS.—First, Lady L. Thynne, Muntham Court, Worthing. Second, Lady J. Cornwallis, Linton Park, Staplehurst. Highly Commended, Rev. J. G. A. Baker, Old Warren, Biggleswade; Lady L. Thynne. Commended, H. Heath, Calne.

COCHIN CHINA COCKS.—Prize, Mrs. Herbert Powick, Worcester. Commended, A. Heath, Calne.

HAMBURG COCKS (Pencilled).—Prize, Master E. E. Keable, Maddell Farm, Berks.

HAMBURG COCKS (Spangled).—Prize Lady J. Cornwallis, Linton Park, Staplehurst (Silver). Commended, Rev. C. J. Down, Semington.

MALAY COCKS.—Prize, C. Ballance, Mount Terrace, Taunton. Commended, W. Manfield, jun., Dorchester; J. J. Fox, Devizes.

WILD COCKS OF ANY BREED NOT MENTIONED.—Prize, J. H. Craigie, Woodlands, Chigwell, Essex (Brabma Pootra). Very Highly Commended, J. Hinton, Hinton, near Bath (Brabma Pootra); T. H. D. Bayly, Ickwell House, Biggleswade (Gold-laced Bartram). Commended, A. Heath, Calne (Brabma); Lady L. Thynne, Muntham Court, Worthing (Gold-laced Sebright).

The Judge was Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, near Birmingham.

DRAKE WITH USELESS LEG.

I HAVE a fine Aylesbury drake weighing about 9lbs., and about ten months old, which has a very weak leg—so much so, that it cannot stand on it, and when swimming stretches the leg right out behind, and does not use it. It is not cramped, neither is there any outward appearance to lead any one to suppose that it is diseased or otherwise. At present I have done nothing to it. It seems to me to be more in the thigh than the leg, but it is not at all inflamed. I should feel obliged if your readers can recommend me what to do?—B. S. P.

[We know hardly what to advise. If the lameness came from the thigh, and if the thigh withers or perishes, we consider the case hopeless. If there is no withering of the thigh, we should examine the joint carefully to find if the disorder be there. We think there must be partial dislocation; if so, it can easily be reduced, and the bird put in a small cage filled with soft straw or hay. In any case this would be wise, as the weight of the bird is too great for a diseased member to support.]

FOOD FOR CAGED SEED-EATING BIRDS.

In your answer to "L. B." on October 8, you state it is a common occurrence for birds to die about moulting time, in consequence of being fed on improper food; but you do not state what is proper.—J. S.

[The best food for seed-eating caged birds I consider is Canary seed, shelled oats and millet, accompanied with clean water, sand and green food; occasionally a little piece of bread, or boiled carrot, potato, or brocoli, and a slice of apple or pear as a treat. Rapeseed I consider too pungent, hempseed too exciting, and both too oily to be proper for constant use.—B. P. BRENT.]

THE SUPER-POSED HIVE BECOMING THE STOCK-HIVE.

I NOTICE an article on the "Uniting of Bees" from "A DEVONSHIRE BEE-KEEPER," in THE JOURNAL OF HORTICULTURE of 29th October last, to which I decidedly take objection. I would most respectfully take the liberty to submit, with your permission, to the readers of your excellent Journal, my very humble opinion with regard to the lower hive becoming the stock-hive.

I have now been a bee-keeper for upwards of forty years, and my experience in manipulating with bees is considered equal to any man's in Scotland; and instead of, as the "DEVONSHIRE BEE-KEEPER" asserts, "having invariably found that a queenless hive placed upon another possessing a queen, the lower one becomes the stock-hive," in every single instance, in all my experience, the hive that is placed uppermost, whether that hive be a queenless one or not, was always found to be the stock-hive.—JOHN BROWN, Road Contractor, Stewarton.

[This letter, taken in conjunction with the testimony of "A DEVONSHIRE BEE-KEEPER" must be held to be decisive of the fact that when bees are united by what a correspondent has termed "super-posing," or placing one hive upon another, they will, at any rate very frequently, adopt the upper one as the stock-hive. As this is contrary to our own experience, the inquiry naturally arises, To what cause are we to attribute this apparent discrepancy? Upon reviewing the circumstances, we perceive that we have, without being aware of it, acted in some measure on a foregone conclusion, and, as it were, compelled our bees to adopt the lower as the stock-hive by closing the upper entrance, and forcing them to work through the lower one. This was the state of affairs which was present to our mind when we stated that we had invariably found that the lower one became the stock-hive. What might be the result of leaving both entrances open or of closing only the lower one we have never tried;

and it appeared to us so much a matter of course to leave the superior stock in its place, and effect the union by placing the queenless one on the top, and compelling all the bees to work through the lower entrance, that this was what we had in contemplation when we offered so positive an opinion. That this opinion was perfectly correct under the supposed circumstances we have not the slightest doubt. Even if the queen first commenced laying in the upper hive, the ultimate adoption of the lower one as the breeding place would only be a question of time, since it is well known that instinct invariably causes bees to appropriate for breeding those combs which are nearest the entrance, whilst honey is deposited at the top; or, as in the case of collateral and uncomb-hives, as far from the doorway as possible. We have known a Nutt's hive stocked by placing a common straw hive over the "pavilion," through which they were compelled to work until they had filled it with comb, when the old hive was taken off full of honey and perfectly free from brood, the "pavilion" having become the stock-box. So long as the reign (we believe) of Charles II. a patent was granted to Nicholas Gedde for the use of stoving-hives on the principle of inserting radles furnished with bars, through which the bees were compelled to work. When breeding was transferred to the lower compartments the upper one was removed, and this process was repeated as often as the season would admit of, and continued year after year. Wildman's hives were on the same principle, and answered perfectly, so far as concerned the bees always transferring their breeding place to the lower hives, although they failed in respect of the quality of honey attained, owing to the combs in which it was stored having been previously bred in, whilst they were also open to the more serious objection that combs built in radles are seldom fitted for breeding, owing to their generally consisting of a disproportionate quantity of drone-comb.

Whilst on the subject of drone-combs, we may state our belief that their presence in too great quantity is more frequent than is generally supposed, whilst it is one of the most serious evils that can afflict a stock-hive. It is to this cause that we should attribute the circumstance related by "A RENFREWISH BEE-KEEPER," in page 69, and not as he imagined to an old queen returning to the drone-laying condition of a virgin, which we believe to be a very rare occurrence, and one which has never come under our observation. We had the opportunity of examining the combs of a stock-hive destroyed this autumn, and in which one-half of every comb consisted of drone-cells, and its proprietor confirmed our impression as to the overwhelming number of drones which had been the result. Our idea is that the queen died when the hive was half filled with combs, which, in accordance with their instinct, the bees completed with drone-cells before a young queen was hatched.

As a contrast to the above, we may instance a stock-hive which has thrown two of the strongest and most prosperous swarms we have seen this season, and in which the only drone-comb was a piece but little larger than a man's hand. We believe that one of the greatest, but at the same time the least appreciated, of the advantages arising from the use of bar-hives is the facility which they afford for limiting the production of drones by removing the combs in which they are bred, and substituting worker-combs in their place.—A DEVONSHIRE BEE-KEEPER.]

QUEENS EXPELLED—UNITING BEES.

Your worthy correspondent, "A DEVONSHIRE BEE-KEEPER'S" reply, at page 20, to "A." on "a queenless hive," has rather puzzled me, wherein he says, "Had you seized her at once and returned her to the hive through an opening at the top, all would have been right." Having now seen scores of queens expelled under every circumstance he could mention, and returned according to his direction, I must say I have never yet seen one single instance of a queen being returned, but had the vexation of seeing her expelled a short time afterwards. I would like to have some of your correspondents' opinion on this matter.

Also, at page 78, in replying to "A Ligurian Misadventure," he says, "My correspondent made a great mistake in attempting to unite bees to his Ligurian stock so soon after its arrival," &c.

Surely "A DEVONSHIRE BEE-KEEPER" must have overlooked the grand effect produced from excitement by travelling when he penned such an assertion, as we Avshire bee-keepers have never found a more fitting time for making unions than when excited by travelling, and never saw a single instance of fighting

either in the case of one or both hives being excited. I may also mention that it is quite a common practice here to unite hives when half-way on our journey homewards from the moors, and considered as safe as in the month of June, when honey is to be gathered from every flower.—STEWARTON APIARIAN.

[I am much obliged to the "STEWARTON APIARIAN" for the kindly tone of his criticisms upon my replies to "A." and "J. N." As the development of truth is the object we both have in view, I have pleasure in submitting to him my reasons for believing that in each instance the replies given were correct.

In the first case he is, in my opinion, mistaken with regard to the queen being "expelled," since it is far more likely that she quitted the hive in a state of bewilderment after missing her footing on the diminutive comb, and being precipitated to the floor-board beneath. The fact is, that a young Ligurian queen placed at the head of a small artificial swarm, with probably not more than 100 to 200 square inches of comb is in anything but an enviable position. Being endowed with the marvellous fecundity of her race, which would enable her to lay sufficient eggs to fill 800 or 900 square inches of comb, she first lays two or three eggs in every available cell, and then wanders hopelessly over the edges of the combs in the vain endeavours to find cells in which to deposit the burden that oppresses her. What wonder then that such an accident should result as has been described by "A.?" Knowing that the queen of a Ligurian stock, which I despatched to a friend at a considerable distance, on the 2nd July last, had quitted her hive with about a hundred workers immediately upon the entrance being opened after travelling, and had been successfully returned, I wrote for particulars immediately upon receiving the "STEWARTON APIARIAN'S" letter, and have had the following reply:—

"Dear Sir,—I beg to inform you that my Ligurian stock seems to get on very well now, although since I last wrote you they have had a most desperate risk. All the bees in my apiary and, I should say, in the neighbourhood had a fearful battle with the Ligurians, and I quite despair of saving them, but they were able to hold out against the attack, which lasted from morning until night. Of course I was absent, or should have put a summa stop to such an onslaught. You are quite correct as to what occurred when they arrived, and when I picked the queen up and placed her on the shelving-board, she refused to enter. I then placed a small glass over the hole in the top, and allowed the bees to come up to her, and they took her down in the most affectionate manner, and next day they worked as well as any stock I possessed. They work well now, and I frequently see them carrying in pollen. . . . Of course their numbers were very much thinned by the fight. My garden was literally covered with bees, and a large number of the Ligurians were seen to come up to her, and they were a very fertile one, for the box got very full of bees, and several times in August they were laying out.—Yours very truly, "H. C."

The foregoing instance sufficiently proves that a queen bee leaving her hive under the influence of excitement may be successfully returned and induced to remain, and that the colony may do well afterwards.

With regard to my reply to "J. N.," I submit that the result proves its correctness. A terrible fight undoubtedly ensued, and that the queen was killed in actual conflict with hostile bees was proved by the fact that she had lost her sting. Any one who is aware with what reluctance a queen bee resorts to the use of this weapon will readily understand from this circumstance to what straits she must have been reduced. The "STEWARTON APIARIAN" may probably be quite correct in believing that bees of the same species might have fraternised amicably under the circumstances. When uniting common bees to Ligurians the case is unfortunately very different. After many fatal encounters the two species have at length been induced to mingle amicably together. By what means this result has been brought about may hereafter be fully explained by—A DEVONSHIRE BEE-KEEPER.

* The box is a large one, being 14½ inches square, by 9 inches deep inside with ten frames.

OUR LETTER BOX.

SPANISH FOWLS FOR EXHIBITION (A. B.).—If your Spanish cocks are in good health and condition, they require no special feeding for exhibition. A little bread and ale may be given with advantage three or four times during the week previous to sending them off. Cold spring water is the best wash for their faces, as the white skin is very delicate, and other applications irritate it.

CHLAP WORK ON BEE-KEEPING (A Subscriber).—You can have "Bee-keeping for the Many," free by post from our office, by sending, with your direction, five penny postage stamps.

MASH ON ROBERTS' (E. L.).—Steaming the bran, &c., as you do is a very good mode of making a mash. To prevent fermentation have an opening at each side close up to the roof. You can have a piece of carpet hung over each opening. Have the floor kept covered with 2 inches depth of dry sand.

POISONING RATS (All Angrily).—Phosphorus pills will destroy them without injuring the poultry if the pills are put into their holes. We never find anything so effectual as tarring a ferret into their runs about once a week.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four days, the average highest and lowest temperature of these days are 47.9 and 34.6° respectively. The greatest heat, 59°, occurred on the 20th in 1844; and the lowest cold, 9°, on the 23rd in 1858. During the period 127 days were fine, and on 111 rain fell.

CRYSTAL PALACE CHRYSANTHEMUM SHOW.

NOVEMBER 14TH AND 15TH.

HIS was the largest exhibition of Chrysanthemum on record.

In the first place, the collection of the Crystal Palace Company, consisting of three thousand plants in bloom, was set in large groups from the crystal basin to the very end of the hothouse division next the bronze fountain, or along the whole length of the nave. These groups were set in various ways, as flower-beds are planted, some in circles, some in ovals, and some in other outlines, but all of them were set as the Crystal Palace people well know how to set up for effect. The plants were well grown, and were in prime bloom. But more of them and their fellows another day.

The four corners of the great transept looked more like the Azalea season with competition collections. The side stands along the transept were filled in the same manner, and all along the centre of the transept were the cut blooms, and also on across the stand in front of the grand orchestra, where some beautifully executed designs of terrace gardens and fountains stood, and where a collection of black Grapes from the Messrs. Lane & Sons, stood also, the only fruit at the Show.

The Messrs. Downie, Laird, & Laing exhibited there some enormous specimens of Henry's Leek grown in the Edinburgh style, for cock-a-leekie, a good old dish not known over the borders. These were all the extras except Mrs. James Stoddard's beautiful imitations of flowers in her own best style.

The competition collections were much on a par with those at South Kensington the previous week, but the collections of cut blooms were in much better bloom, so to speak. The first, second, and third prizes went very nearly to the very same growers who were the winners over the water, and the kinds of plants were not much different, while many of them were the very same kinds, if not the same plants.

Mr. Bird had the thirteen seedlings there which I described from his nursery the week before. I heard they mostly got first-class certificates, but did not see the awards, as the Judges were not quite done with their part of the law. Mr. Salter did not exhibit there at all.

At this point I discovered a plot, or a conspiracy, of the nature of those of the time of Waverley. The Scotch again in deep for it against the English crown. You recollect I said that the best white Chrysanthemum, and

the newest at Kensington Gore, was the White Queen of England, a new sport yet in the hands of the Messrs. Downie, Laird, & Laing. A Scottish lady, the Lady H. St. Clair, or some one on her ladyship's behalf, has claimed the White Queen of England for a patronymic, against the law of nations and the pride of our common country. This is, indeed, a *casus belli* between the north and south. The clans will, of course, call this flower Lady St. Clair; but in England the sport from our own Queen of England will surely be bought and sold as the "White Queen of England." The same firm has a Picotee sport from this same sport, and why not call that Lady St. Clair at once, to keep down old feuds? At all events my mistaken "White Queen of England," is the best of all white Chrysanthemums.

Mr. Turner, of Slough, had a first prize for a collection of the newer kinds; and Mr. A. Forsyth second, for the same. Mr. Turner's kinds were—Mrs. Turner first, of course, a pure white hybrid, or intermediate between large and Pompon; Pictorium roseum, a large bloomer after Alma and Alarm; Jewess, a most profuse bloomer and one for a first-rate specimen, not so dark as Mount Etna, but of a fiery tint; Queen of the Isles, next to Cassandra; Yellow Perfection, slightly buffish; and General Hardinge, a stout large flower in Indian red.

Mr. Forsyth put up seven plants for six, all newish, of which Rifleman is the best and newest; then Emily, a bluish white; Boadicea, a large, rough, round bloomer, after the tints of Dupont de l'Eure; Pandora, same tint as Golden Queen of England; Golden Hermione and Golden Trilby, both good yellows; and Lady Hardinge, larger and lighter than Globosa Stellaris. All in much better condition than they were at South Kensington.

The first collection of sixes (Amateurs), was that of Mr. Ward again. He is the gardener of W. Fowler, Esq., Tottenham Green, and his style of growth is the best model in England. His kinds were—Beauty du Nord, Salomon, Pilot, General Havelock, Defiance, and Golden Christine, which seems the favourite with all the trainers.

Second prize to Mr. George, gardener to J. Nicholson, Esq., Stamford Hill, with Alma, Golden Christine, and old ditto, Auguste Mié, Vesta, and Insigne.

Third to Mr. John Pratt, Hackney Fields, for Vesta, Christine, and Golden ditto, Chevalier Domage, another seeming favourite; Dr. McLean, and Sulphurea superba.

Fourth prize to Mr. Glover, gardener to R. C. Lepage, Esq., Tulse Hill, for Chevalier Domage, Vesta, Mount Etna, Golden and nearly a white Christine, and Aregina.

There were six more collections in this class and another one which had a fourth prize, from Mr. Webb, gardener to H. Walmesley, Esq., Clapham Park, Aregina, Alma, and Pilot, three of a tint altogether; then Chevalier Domage, Trilby, and Golden Christine.

Mr. Turner was first amongst Nurserymen in this class of sizes. His kinds were—Julie Lagrave, Madame Camerson, Golden Christine, Mount Etna, Hermion (not Hermione), and Aregina; and Mr. Forsyth was second.

But in the Pompon class, Mr. Forsyth beat Mr. Turner by one turn of the die. Mac's plants were capitally done. The kinds were—Durand, Hélène, Salamon, Ste. Thais, and Golden Cedo Nulli. Mr. Turner's kinds were—Bob, Général Carrobert, Cedo Nulli, Durand, Bijou de l'Horticulture, and Brilliant.

Among the Amateurs in this class for six Pompons, the first was Mr. Hutt, of the Halfway House, Hackney Fields. The kinds were—Golden and old Cedo Nulli, Andromeda, one of the very best for specimens, a light creamy thing; Miss Julia, Salamon, and Général Carrobert.

Second, Mr. Ward aforesaid; third, Mr. Weston, the best speller; and fourth, Mr. Glover, kinds as above, to save room and the time and temper of the reader.

Here stood a Crystal Palace Pompon Eva—a most seemingly good thing for a specimen—a yellowish flower, tipped with brown. For single specimens of Pompons Mr. Hutt was first with a fine Golden Cedo Nulli; second to Mr. Cook for Ninon; third to Mr. Ward for a Cedo Nulli; and fourth to Mr. Weston for ditto.

The first in single large specimens were Mr. George and Mr. Ward; but the cards of the rest were upside down when I passed. One of the corners of the transport was devoted to pyramidal trained plants, but all the growers had them done too still. Mr. Fiveash, gardener to Mrs. Sillem, Clapham Common, and if his plants were a little more loose they would have been perfect; they were most beautifully flowered. The kinds were Cedo and Golden Nulli, Andromeda, Adonis (fine), Hélène, and Bob. Mr. Hooper was second; Mr. Glover third with stiffer plants, much of the same kinds, which make the circle of my round; and then the single blooms, with them Mr. Bird soared high above all he surveyed. The crystal glass bottles again, and again the silver tankards for his Queens of England, and his wrath could hardly be appeased at the Scottish plot against the White Queen of England. The chances are that he will buy up the stock from the canny Scots, and have it next time in a silver goblet under its proper name. His large nosegay of Jardin des Plantes was the finest thing ever seen at a show. Remus is after the tints of Aurora Borealis; then followed in nosegays Hermione, Gluck, Sulphurea superba, Tribly, Alfred Salter, Admirable, Yellow Perfection, Triomphe du Nord (immense blooms), Old and Golden Christine, Beauty, Thémis, Queen of England, Golden ditto: two nosegays of Vesta; twenty-four single Novelty (and such novelties!), with Progne, Princesse Marie, Alma, Queen of Yellows, Madame Poggi, Etoile Polaire, Julie Lagrange, Marguerite de York (very large yellow Anemone after Gluck), Christ-pher Colomb, Aimée Ferrière, Dupont de l'Eure, Madame Mielz, Annie Salter, Miss Kate, M. Dechamps, Madame Lebois, Stellaris globosa, and Wonderful, and a most wonderful good thing it really is; try it against a hawthorn-coloured Chrysanthemum, Dahlia, or Hollyhock, and sigh for their saddest or tristis-like looks. Then he had a beautiful of single specimens too long for my room, and another lot for open contest in six sides—as six Stellaris globosa, six Dupont de l'Eure, six Cassandre, six Novelty, six Yellow Formosa, and six Hermione, all “trimmers;” then the seedlings aforesaid.

The next greatest and most successful exhibitors were Mr. Cattell, of Westerham, Kent, and Mr. Wilkinson, of Old Ford, Bow—both nurserymen, and both in a tie of first-rate prizes for best twenty-four cut blooms. I shall just go through them and stop for this week; but I shall have another turn some day with the “Good Gracious” things and new inventions which I noticed at the Crystal Palace, the basins, their temperature, their furnishing, my own friend's “fly-flappers,” and the natural bent of all large and small Chrysanthemums, from the note-book of the best bloomer of them in England.

Mr. Cattell set off with Miss Kate first, then Jardin des Plantes, Novelty, Fabius, Beauty, Cassy, a reddish-buff Hermione (not one), Nonpareil, Golden Queen, Mrs. W. Holborn, Pio Nono, Queen of England, Arthur Wortley, Plutus, Alfred Salter, Lucidum, Glory, Alma, Madame Mielz, Thémis, Goliath (one of the oldest and yet of the very best), Aimée Ferrière, Yellow Perfection, and Teronite: all these were A No. 1. Mr. Wilkinson's the same. The kinds—Glory, Thémis, Goliath, Lord Elgin, Yellow Perfection, Argente, Madame Andry, General Hardinge, Beauty, Plutus, Favourite, Queen of England, Nonpareil, Anaxo, Alma, Dupont de l'Eure, King, Boadicea, Jardin des Plantes, Lucidum, Victoria roseum, Alfred Salter, Campestri, and Mrs. W. Holborn. J. DEATON.

WINTERING GERANIUMS AND FUCHSIAS THAT ARE GROWING.

I HATE noticed your remarks respecting wintering Geraniums and Fuchsias, but have seen nothing to guide me as to the best plan to winter Scarlet and Fuchsias that were cut down six or seven weeks since, and have broken well. The shoots are now about an inch long. Should they be kept the same as plants not cut down? No heat can be given them through the winter, but they can be kept safe from frost on shelves near staircase windows, where they can have plenty of light, and such warmth (only), as the air of the house will afford. Can late-struck cuttings of Scarlet Geraniums and Pelargoniums be kept in the same manner—viz., on the shelves with only the warmth of the air of the house?—A LADY.

[All Geraniums—that is, bedding Scarlets, and all Pelargoniums, or greenhouse show Geraniums (but there is no natural difference at all between the two), and all Fuchsias that have been cut down early or late in the autumn, and have broken well, like your own plants, must be grown on slowly the whole winter through. This has nothing to do with the modes of keeping dormant Fuchsias and Geraniums over the winter, and they require to be treated as nearly as possible in the same way as all greenhouse Geraniums. When they are thus cut late in the autumn the best way is to give them bottom heat till they have broken well, and then good greenhouse culture for the rest of the season. Your plants ought to do very well where you have them. Frost and damp are not likely to get at them there.]

A FEW DAYS IN IRELAND.—No. 4.

THE UNDER SECRETARY'S LODGE, PHOENIX PARK.

WE have no recollection of the house or ornamented gardening at this place, occupied by Major Larcom, and that, we have no doubt, owing to our own carelessness in not asking the intelligent gardener, Mr. Scott, to give us a view of the same.

A practice prevails in many parts of England of showing a visitor the kitchen garden and forcing-grounds merely, and unless directly appealed to on the subject, the mansion and the accompanying ornamental grounds, which often form a key note or centre to the whole, are never honoured with a visit of inspection. Sometimes there may be reasons for this, as the wish of the family to secure privacy, which, in such circumstances, ought not to be broken in upon without consent sought for and obtained. Gardeners even there are generally considered a privileged class, that do not come under particular rules and regulations; and, certainly, few things are more annoying than when, after going to the expense and trouble of travelling many miles, you are coolly told that you cannot be admitted, as no visitors are allowed—or only on a certain day of the week, and you have come on the wrong day.

If an order, however, is given to that effect, whether he likes it or not, the gardener cannot help himself; he ought as a servant to carry out the wishes of his employers. In some cases we have gone round places and felt in a sort of purgatory, because we saw that the gardener was anxious to avoid all observation—was, in fact, dreading to be seen. Better, far better, not to go at all. Even when taking visitors, and especially gardeners, round, when such a practice is even more than courteously allowed, the gardener will do well to avoid meeting directly any of the family if it can be done openly; but anything like hiding or concealment ought thoroughly to be scouted, as whenever seen it always leaves an impression that there was something needing to be concealed. Openness and straightforwardness in this and all other matters are always best.

Two things in this respect are most gratifying at the present day—the liberality of noblemen and gentlemen in permitting their grounds to be seen, and the general propriety of conduct of visitors: thus testifying, by the only means in their power, their appreciation of the boon and privilege conferred. We must own, however, that the mere feeling of curiosity, and that, too, in the higher classes of visitors, not infrequently triumphs over their good sense, and in other respects their propriety of conduct—for instance, here is a place open at certain times to the public without let or hindrance, the mansion alone is retained as a place of privacy, and, though this is well known, some will pop their heads in at the drawing-room windows, and even open the doors and walk into the rooms. There, again, are several other

places where the whole park and pleasure grounds are open, where extensive lawns are set aside for the public to amuse themselves with different games and recreations if they like; but a small portion is shut off that the members of the family may enjoy the charms of privacy. And there some curious Paul Pry individual will be sure to intrude himself, or herself, perhaps as much to the amusement as the annoyance of the proprietors; but certainly to the annoyance and mortified chagrin of all well-conducted visitors. We should be no advocates for Lynch law; but as in all such cases a silent appeal is made to our honour, and the whole premises, as it were, put under our care and keeping, we would not be sorry to see such individuals so marked out for social reprobation as would amount at least to a moral tarring and feathering.

Perhaps we are wrong altogether in alluding to such a matter here, though having evidence that such Paul Prys are as numerous in Ireland as they are on this side of the water, for certainly they bear no reference to the present case. Farther than that I did not see the mansion; and that I attribute partly to the shortness of time, and partly to my admiration of the fine kitchen garden and the mode in which it was filled with first-rate vegetables, though plenty of good old-fashioned flowers were also present in the borders.

The fruit trees seemed in capital order, though not bearing in their usual style this season. But Cabbages of some half-a-dozen kinds—some of them, as the Rose, a Drumhead variety, large enough to fill the mouth of a bushel basket, and others vigorous of all ages, and all colours and hardness and softness of heart, to suit all fancies and tastes. Cauliflowers strong and in different states for succession. Lettuces like large Cabbages, crisp and sweet as a Hazel nut. Celery high-earthed-up already on the 13th of September, and such a height, too, as is not often seen in England. Onions in plenty drying; and Peas and all sorts of Beans in abundance showed that the useful was not sacrificed to the merely beautiful in this garden.

What, however, chiefly struck our attention was a short range of houses (vineries chiefly), which were just rather too well supplied with fruit. The borders of these vineries had open pipes some 3 inches or 4 inches diameter, standing upright some 18 inches above the soil of the border, communicating with a chamber below the border, and that chamber connected again with openings into the atmosphere of the house. These open pipes were in two rows—one a few feet from the front glass, and the other near the front of the border, the pipes standing something like 3 feet from each other in the row. We should suppose that such a border was covered with litter before forcing was commenced, and that the mouths of the pipes outside and inside might be regulated according to the weather. Many would have liked the means of heating that chamber, and thus obtained both heated and moist air into the house. There was, however, no means of doing so, nor yet did we gather from Mr. Scott that he had any particular wish that it should be so heated. He seemed, however, to attach great importance to the air from the outside passing directly through this chamber, and thus becoming mellowed and softened before it entered the house. We cannot say what the general effect had been in this house, as most of the earlier kinds had been cut; but one Vine of the Barbarossa beat everything as to weight and quantity we had ever seen or heard of. The Vine, though confined to one rather, did not seem all one stem, but from top to bottom of the house it was a wide mass of bunches almost touching each other, and individually each bunch nearly as long as the arm of a short man. We regret now that we did not count the bunches and measure their exact length and the breadth of the shoulders. Some of the best were colouring well, but others were showing signs of distress, and Mr. Scott spoke of removing some of the smaller bunches. Like many of us, he was a little over-covetous. Had less than a half of these glorious bunches been left the crop would have been magnificent.

We cannot say we have done much with this Grape. We are convinced it needs an early house and as much heat as a Muscat. We have pretty well removed it from a late house, as we find the wood did not quite ripen enough to insure us a good crop, and yet there seems no certainty even in this. The next best regular crop we have seen of the Barbarossa, though the bunches were small, but well coloured, was in a small greenhouse at the Cemetery at Luton, under the care of Mr. Godfrey, the heat to keep out frost being supplied from a portable iron stove. On making inquiry about it the other day, we found the Barbarossa had been taken out, because though it fruited freely, it could

not be ripened time enough so as to be cut before the house had to be crammed with bedding plants.

We confess that notwithstanding the immense crop, and the immense bunches of this Grape, under Mr. Scott's management, there is yet so much said, pro and con, of clambered borders, heated and unheated, that we feel sure that an account of Mr. Scott's views on the subject, from his own pen, would be acceptable to many readers besides the writer.

R. FISH.

ERRATA.—At the end of Phoenix Park, page 90, state that in the figure representing the cross section the slopes should be shown sharp, not rounded. And at page 91, showing the mode of training, the two crosses should be seen going over the mouth of the pot—in fact, that gives them steadiness.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 12TH.

FLORAL COMMITTEE.—A thorough November day, in which everything looked miserable, dreary, and dirty, with an atmosphere somewhere factiously described as a cross between a Scotch mist and pea soup, in which colours were defiant of all attempts to define them, and with the room miserably cold, formed a congeries of circumstances not over-favourable, or too lively for a Committee day. I suppose the acting rulers considered that the ardour of the Floral Committee was sufficient to warm them; but certes a fire would not have been unpleasant, however delicate the compliment may have been, and yet there were some really good things there, and several high awards were given.

Mr. Salter, as usual, furnished a large number of seedling Chrysanthemums, both of the large-flowering sorts and Pompons. These comprised Duchess of Wellington (Salter), rosy lilac, with white back and petals, giving the flower a silvery lilac appearance. Lord Ranclagh, awarded a First-class Certificate, light red orange, beautifully incurved, but not sufficiently expanded, and so looked flat. Carissima (Smith), a sweetly delicate flower, bluish white, streaked a little with lilac at the back of the petal, and in blooms which I saw afterwards at Hammersmith most decidedly so: this was also awarded a First-class Certificate, and will be quite a lady's flower. General Slade (Smith), an immense flower, beautifully incurved, colour an Indian red, tipped with orange: this had already received a First-class Certificate, and fully maintained its character. Spörker, a very beautiful medium-sized flower, red chestnut with orange tips, incurved; very fine and distinct: this received a Label of Commendation, and will form a most desirable variety, its habit being excellent. Lucinda Pompon, rose and lilac, very full, will be better. Citronella (Smith), yellow hybrid. Acis (Salter), pale sulphur; fine, free, and full, and its habit excellent. Cupella, very dark red chestnut; good habit. Medora, Brazen Mirror (Pethes), like Jonas. Stylphide, delicate lilac, tipped bluish. Mr. Salter also sent *Astelea Banksi*, a curious-looking variegated plant in flower. *Galceobdolon luteum maculatum* alba, *Sansevieria carnea*, fol. var., Japan, the true names—formerly known, Mr. Salter says, as *Synpoegeon jaburana*! and a species of *Begonia* from Santa Martha, for which a Label of Commendation was awarded. It is a very large green-leaved variety, with a smooth, shining surface.

Mr. Bull sent *Caladium maculatum*, *Chrysanthemum La Folie* (yellow), Diamond (bluish), and Madame Heine (white), something like Mrs. Turner, but with the white more pure (a Label of Commendation was awarded for this), and *Agave americana* elegantissima, beautifully variegated with white. This received a First-class Certificate.

From Mr. Low, of Clapton, came *Dendrobium Lowii*, from Borneo, a very beautiful and striking variety, of a lovely primrose, with a fringe of red hairs. This received a First-class Certificate, and adds another to the many interesting plants introduced by this enterprising firm.

Mrs. Redgrave sent nine plants of *Solanum pseudo-capsicum*, a plant much used on the Continent for in-door and table decoration in winter, when its bright orange red berries give it an interesting appearance. This is different from *Solanum capsicum*, the latter being more dwarf, and with broader leaves.

Dr. Neligan, of Dublin, a first-rate florist and enthusiastic cultivator, sent through Messrs. Dickson, Hogg, & Robertson, of Dublin, some blooms of a sport from *Cedo Nulli Pompon*, of a lilac colour, and which he proposed to call *Lilac Cedon Nulli*. The blooms were hardly in a fit state to judge.

Mr. Veitch, of Chelsea, sent *Graptophyllum versicolor*, a stove plant from India, with blotch in centre of petal. For this a Label of Commendation was awarded. Also, *Stenogaster concinnum*, a curious-looking Lobelia-like flower, very small (for stove), lilac tips to petals, and with the throat spotted. This had received at the June Show a Second Prize, it was now awarded a First-class Certificate, and was stated to have been in bloom since May. It was quite a gem for ladies, and would do admirably for Miss Maling's new cases in the front. The same gentleman also sent *Alsophila coccinea*, a species of tree Fern from Manilla. For this a First-class Certificate was awarded. Also, three pairs of the beautiful little *Sonchella margaritacea*, splendens, and superba. For these a Special Certificate was awarded; and some plants of the *Wigandia caracasana*, noticed by me some time back as so much used in Paris at present.

Mr. Standish, of Bagshot, sent two first-class Ferns, *Woodwardia orientalis*, and *Lomaria elongata*, the former having fronds 4 feet in height, which when young are of a beautiful rose pink colour, supposed to be hardy; also *Lomaria elongata*, a very dark foliaged variety, known to be perfectly hardy. For these First-class Certificates were justly awarded.

Messrs. Osborn & Son, of Fulham, contributed an *Aucotochilus*; and, finally, Mr. Risher, of Regent's Park, very kindly sent a nice plant of *Eucharis amazonica*, a beautiful snow white flower mentioned by me as seen at Thibaut & Keteleer's, at Paris, and which he kindly brought in order to give persons an opportunity of seeing it. He sees it largely, and grows it very successfully, having it in bloom for six months in the year.—*D. Deal.*

FRUIT COMMITTEE.—A Meeting of the Fruit Committee was held on Tuesday, November 12th, J. B. Haig, Esq., in the chair. A collection of Muscat Grapes was exhibited from Mr. D. Thomson, Archerfield Gardens, near Drem, N.B. They consisted of Muscat of Alexandria, Tyrningham Muscat, Boswood Muscat, and an early variety of Muscat, which is supposed to be distinct from any other in cultivation. This exhibition was made at the request of the Committee, who desired to see all these varieties grown in the same house, and under the same circumstances, and to ascertain wherein the Early Muscat differed from all the others. The Muscat of Alexandria and Tyrningham Muscat were long, tapering bunches, loosely set, and the berries were quite plump, and of a greenish-yellow colour. Boswood was a short, thick-set bunch, and the berries were much more advanced in ripeness, and had begun to shew and change to the brown raisin colour; but the Early Muscat was completely shrivelled, had lost entirely its yellow colour, and had become perfectly brown and raisin-like. The flavour was particularly rich, and the sweetness was much greater than in any of the others. In the opinion of the Committee this is a first-rate Grape, and deserves to be introduced into cultivation.

Mr. Thomas Gray, Hambury Hall, Westbury-on-Trym, sent a bunch of Barbaress, and of Muscat Hambury. The latter was a very creditable bunch, in size and well set, and the flavour was rich and excellent, but the Muscat aroma was not so powerful as usual.

Mr. Melville, of Dalhousie Park, near Edinburgh, again submitted a small bunch of his seedling Grape, Champion Hambury Muscat. The berries were now much better coloured than on the previous occasion when the fruit was exhibited, and were of a uniform and even dull red or foxy colour. The flesh was firm, very richly flavoured, and with a fine Muscat aroma. This was highly approved by the Committee.

Mr. William Masters, Nurseryman, Canterbury, sent a seedling kitchen Apple, and Mr. Ball of Chelsea a seedling dessert Apple, but neither of them was considered worthy of being added to existing ones.

Edward Gibson, Esq., of Alton, near Sheffield, sent a dish of Kitchen Muscat Apples, but they were as yet unripe, and appeared as if they had been gathered too early, as they had not any brown to shew.

Capt. Taylor, of the 10th Regiment of Artillery, without name, offered to send a fine specimen of a very richly coloured dish of his crimson apple, and with a bloom over the fruit. This was highly valued, and is a Northern Spy. The colours were not ripe.

Mr. Dowling again exhibited the dessert Apples which were sent to the meeting under the name of Long Nose, from the nursery of J. B. Haig, Esq. It is a small, conical fruit, with a yellow ground colour, and a richly spotted. The flavour had much im-

proved by keeping, and the Committee were of opinion that it is an excellent dessert Apple.

Mr. William Paul, of Cheshunt, sent an interesting collection of veg-tables, amongst which were several varieties of those beautifully-variegated Curled Kales, which seem to be coming so much into vogue, and which may very well serve not only as culinary plants, but as "fine-foliaged plants" for the decoration of pleasure grounds during the dreary months of winter. There were also in the collection roots of *Cherophyllum bulbosum*, about which it is now endeavoured to get up a sensation as being a substitute for the Potato. The roots were about 2½ inches long, and were about the size and shape of the small Dutch Horn Carrot. Query. What weight per acre will they grow? The Brussels Sprouts in the same collection were very fine, as were also the white Spanish Onions, and an immense Vegetable Marrow called Prince Albert Improved.

Messrs. Downie, Laird, & Laing, of Edinburgh and Sydenham, sent some enormous Leeks, called Henry's Prize Leek. They ought to be called the Truncheon Leek. They were finely blanched to the extent of 10 inches or 12 inches, and are a great advance upon any other variety we have seen.

ALTERATIONS IN AN OLD ICE-HOUSE.

I PROPOSE altering my ice-house (which at present keeps the ice very badly) in conformity with the plan described in your Journal of November 5th; but I wish first to ask a question or two.

Mine is a large ice-house; and, like that named by Mr. Beaton, has a passage leading into the side of the vaulted dome. This passage has an outer door and two inner doors; but the dome is perfectly six-tight at the top. I propose removing the two inner doors and placing a six-inch common tin ventilator in the outer one. Will this be sufficient as regards the door? and will a four-inch iron pipe let in through the centre of the dome, with a kind of umbrella cap over it, be sufficient for the top? If not, how large would you advise?

The ice-house is covered with a mound of earth, and has shrubs growing over it: therefore a mere hole into the dome would allow of dead leaves, &c., as well as any animal going down it. I have hitherto had straw placed round the sides of the well; this I propose to discontinue, as Mr. Beaton directs, and merely to cover the ice with it about a foot thick on the top.—A SUBSCRIBER.

[These are exactly the alterations I should recommend; but I would put a six-inch-bore glazed earthen pipe, or pipes, in the dome instead of iron ones, and I would have a bent pipe at the top—or one bending two ways—which would be better among shrubs than an umbrella cover. Also, as the house mound is covered with shrubs, try one-half of it with straw down the side, by way of experiment, and note how the ice on the strawed side endures compared with that against the bare walls, and let us know the result.—D. BEATON.]

GLADIOLI.

YOU would confer a favour by giving a list of the early and also strong-blooming Gladioli; the Gladioli being a plant that blooms at such varied periods it is almost impossible to get six or eight blooms or spikes in a small collection at the same time.

During the late summer such varieties as Den Juan, Mons. Blouet, Cunari, Janire, Pallas, Brechelyensis, and Fairy Rouget bloomed the earliest (August 20th, the above were exhibited), and I have had blooms, not more than one or two at the same time, up to the present date. This morning, November 4th, I cut a splendid spike of Adonis, and have several more to bloom. The Gladioli, like the Tulip, seems to enjoy the soil and atmosphere of the north, and for this reason has become a great favourite and much admired.—J. BLACKBURN, *Sunderland.*

The flood of new Gladioli, and the rapid disappearance of the old kinds, render such a list as you want very uncertain. We have consulted the heads of the Gladioli fancy, and that is their verdict. But Mr. Standish, the largest raiser of them whom we know, has promised to set apart a piece of ground next year on purpose to prove the earliest, the middle season, and the late-flowering ones for the use of his own customers and our subscribers.]

CONSTRUCTION OF A PIT.

The several articles in your Journal upon pits and green-houses have enabled me to build the following pit, of which I give you the particulars for your criticism, and also for the benefit of your subscribers, should you think it of any service to them.

Upon the walls is placed a frame 5½ feet by 2½ feet, in which sashes are hung containing 1 foot of glass opening outwards. The lower part of this frame forms the wall-plate, and the upper the plate for the rafters, 2½ feet by 1½ foot, and 6 feet 4 inches long. The ridge-board is single, but has an opening on each side of 4 inches wide, formed by the rafters not being glazed there, and covered with a six-inch flap opening by a pulley inside, which flap shuts down upon the rafters and upon a metal bar inserted between each, and having a flange to receive the glass, similar to the metal bars now often used for sash windows instead of wood ones.

The eaves-board for receiving the lower part of the glass is 5 feet by 1½ foot, and underneath is a trough for the rain water, emptying into a slate tank in the house, having an overflow into the drain before alluded to.

The pit is divided in the centre by a wall of brick-on-edge carried up as high as the outer walls, and with glass for the remainder, with a door half of glass. Here there is a larger rafter, as well also, as at the two ends, 3 feet by 2½ feet. In each division are six sashes, three on each side, all opening outwards. The door is at the west end, and over it there is a window opening outwards.

It is heated by a flue made of two bricks on edge set on foot-panels, and covered with similar ones, and standing about 18 inches from ground level. The furnace is inside the west end, but fed from without. It is 18 inches long, with a dead plate in front of the bars 6 inches wide, three bricks on bed deep and 14 inches wide. The furnace-door with a dead plate in front, and 1½ inch from the outer one, and the ash-pit door with a regulator. The flue rises 16 inches in a gentle slope from the furnace-bars to the bottom of the flue, and runs along the front, east end, and north walls, 1 foot from the front, and 6 inches from the others, having a rise of 9 inches in its whole length to its entrance in the chimney, where there is a damper. This flue draws admirably. I have had a stage with three steps made of splices as described in the *Kimpton Hoop House*, Vol. XX., page 55, for the back or north sides of the pit, and there is plenty of room for a shelf suspended from each side of the roof over the path. The space for stages is 3 feet 4 inches on each side, and for path the same width.

Would you advise these stages to be covered with sand or pebbles in the summer? as if so, by then inserting an extra splice between the others the sand would be retained.

Round the furnace about 2 inches from the fire-bricks is a wall, which is carried up about 6 inches above the top of the furnace, and with a stone over it, forms a hot-air chamber 3 feet square, upon which I can place sand and a hand-light, affording a striking-bed for cuttings.

My object in having a division in the pit was to have bedding plants in one part, and more tender plants in the other; but unfortunately I was obliged to have the entrance at the west end, and the furnace there, and this is the hottest part of the flue, and here I get more heat than is requisite for the bedding plants; the flue on the north side being nearly sufficient.

Now, I want your advice as to the best plan of using this part of the flue. After reading Mr. Beaton's article in your last Number, it occurred to me, that if I surrounded the whole of the flue from the neck of the furnace, by continuing the wall now round the furnace, brick on edge, along the front of the flue up to the wall forming the division, and then covered it as Mr. Beaton does, I should have a length of bottom heat which would be useful for setting Roses and spring bulbs upon; and by having a slide in the chambers so formed, I could admit hot air into the pit if wanted; and on the contrary, by having a slide in the outside wall, could admit cold air if the chamber was too hot. With this plan would there be top heat enough for the things having the bottom heat? As the other part of the pit would be the warmest, the plants in the bottom heat after being started could be removed there, and when I was not forcing anything, the outside slide and a deeper covering of earth would keep down the heat in the first or cool division. Would you say if you think my suggested mode of appropriating this part of the flue is feasible? On the opposite side I send you a sketch of the ground plan and west-end elevation of the pit.—C. D. DANVERS.

P.S.—I have not made any provision for letting cold air into the chamber except to cool it, as I do not want a circulation of hot air into the house; but I could easily admit cold air by taking out a part of the brick outside by the furnace-door.

[I am sorry that the answer about cold pits was sent off two days before this letter from Mr. Danvers came. I could

- a a, Flue.
- b, Suggested enclosure for hot-bed.
- c, Place for bedding plants.
- d, Warmer part.
- e, Steps to furnace.
- f, Fuel.
- g, Drainage.
- h, Door.
- k, Chimney.
- l, Glass ventilator on pivot.
- m, Shelf.
- n, Hot-air chamber.
- o, Slide to admit air.

It stands with its ends fronting east and west, as the position would not admit of its being placed, as you prefer, with its ends north and south. It is 22 feet long and 10 feet wide, inside measure, and 8 feet 4 inches high to the ridge-board.

It has hollow nine-inch walls 4 feet high, 2 feet 6 inches being sunk below the ground level, and the bottom is well drained by a layer of coarse stones, with smaller ones at top, and a drain leads away any water that may percolate down the outside of the walls below the surface as also the waste water from the roof.

hardly find fault with it, as he seems to have carried out what I have so often recommended; but, having described the minutiae so often, perhaps I have not been minute enough as to building, &c., and his letter to a person who does not wish to go back to other volumes will give him all he needs. The flap for back air will do very well, but if glazed it will look neater. The mode of heating by flue is also the same as mentioned the other day, where it would not be convenient to get down for a stove-hole—that is, taking it round the sides and the farther end. The plan shown of a flue in the middle is meant to be applicable only to a house for bedding plants; and knowing that the one stout flue would be sufficient for that purpose, the want of it on either side would permit of many things being kept below the flower-stands without being prematurely excited into growth. If we took a flue all round we should build it on the firm or concreted ground, and not raise it from it, as that adds greatly to the expense. We think the graduated stage on the north side will be too low if there is to be a level platform on the south side as high as the glass; it would be a different thing if there was a similar stage on the south side, as at Kimpton Hoop.

There is less gained by having the furnace inside the house than is generally imagined; the heat will be sure to go forward, and a yard or so immediately over the furnace and plate will be cooler than a yard farther on. However, we prefer having a place to light the fire outside unless a house is large enough to permit a small place to be shut off to keep all the dust there, and enable a fire to be lighted comfortably on a dark wet night.

It has been repeatedly shown how a space round a flue may be turned into a hotbed, and it is a great gratification to us that whenever our friend Mr. Beaton takes up a subject, he not only throws light upon it, but imbues other people with a portion of his own enthusiasm. After thinking the matter over for ten minutes, we think there are two best ways which you may adopt for keeping bedding plants and having a forcing-pit in the same division. The first plan would be to shut off the front part with a division of sliding sashes, as mentioned in answers to "N." page 71, paragraph 10. The second and best would be to have that front part made into a pit, by taking a wall up at the pathway, either high enough to put sashes on it, and on a rest at the front wall; or just low enough to enable you to place a wooden box on it supplied with small sashes. This would be better than having hand-lights, though if you liked, the roof of your box might be ridged instead of flat or sloping; the front being fixed, and the back moveable for air and work. If any of these should be decided on, we would make the flue wider and stronger there, and then make open dry flues from it to the front wall, and the wall at the path with bricks and clinkers, and raise with rough stones 6 inches above the flue. You can either pour moisture among these stones for bottom or top moistures, or you can have a slide as you propose, and have an evaporating-pan, as Mr. Beaton proposes; and by means of an open funnel or two inside you can let up dry heat and moist heat as you wish. With such a contrivance, and a covering—say of woollen cloth, and calico underneath to throw over the glass on a cold night, you could easily keep such a place at from 60° to 70°; whilst by the admission of air you could have your bedding plants at 40°. I forget to say that the rough stones should be covered with clean gravel, and then with sand; but if you could get such a thing a little tan would be excellent for setting your pots on or in.—R. Fish.]

DESTROYING THIRPS.

I HAVE some *Azaleas* infested with thrips, and have fumigated them with tobacco paper until I nearly killed the plants, the leaves appearing as if burnt. I have syringed them with a mixture of sulphur, soft soap, and tobacco water, and, lastly, have immersed them in a tub of tobacco water, allowing them to remain quite under water two hours, and after all these appliances the thrips are still alive. What more can I do?—YORKSHIRE.

[We hope you kept the pots and the soil out of the tub, or we would not give much for the plants. Yours is one instance out of many of the more than nine stitches being required, when one timely one would have saved all the bother. You very likely killed every thrip alive; but as you did not, and could not, well scrub every part of stems and leaves, you left myriads of eggs ready to be hatched under favourable circumstances. If the plants are still likely to live we would get

some size water, just as much size being in the water as will make it feel sticky between the fingers. Heat it to 140°, and immerse the whole of the head of the plant in it. Then take it out and leave it in a shady place for three or four days, then shake it well, and wash thoroughly with warm water. Keep a cloth over the pot.]

THE IN-DOOR PLANT CASE.—No. 2.

(Continued from page 131.)

I PROCEED to-day to give a minute detail of the proper management of one of these cases when it is wished to keep it at stove temperature, that temperature varying in summer from 85° to 85½, and in the winter from 65° or 70° to 55°. I do not myself often have the temperature much higher, though one night when the room temperature was below freezing in the place where one stood, I raised the heat at eight P.M. to 40°, and found it at nine next morning to be 65°. This was, of course, much too great a heat to use, but I just wanted to see what could be done if necessary.

The principle, as far as I had a principle, in the construction of these cases was to heat so large a body, and to economise so carefully the already heated air as to render the escape of heat, which had been once attained, a very slow proceeding. At the same time, working in so small a compass, the roots of the plants were exposed to too great heat unless well protected by a thick layer of sand, this sand was, therefore, made to serve two purposes—protecting the roots and retaining heat. My usual plan has been to fill the plant case with hot water to the amount required very early each morning, and then as soon as the water became very nearly cold to refill again. This refilling, if done rather late, maintains the temperature of the case at a good degree for a longer time than the first does, as it has the advantage of finding the case quite warm. And here lies the chief variation for the coldest weather—by giving a little fresh heat half-way through the day, we maintain the day temperature at a higher degree, which is always proper; and are able at the same time to delay the night-filling till as late as nine or even ten o'clock.

I have also made great variations in the quantity of hot water used. A single water-can full put in in the early morning and late evening is all I allow at the present season for a warm greenhouse temperature. But the sunshine, when there is any, brings up the heat immensely, so as often to render the night-filling unnecessary, except for giving air; and when there is no sunshine it must be remembered that the heat ought to be lowered. So much, then, for actual heat given for heat's sake.

We now approach the question of air-giving; and when a certain temperature much above that of the room is required, it is evident that a greater degree of heat will be needed to make up for and supply, the absolute waste, caused by the equalisation of temperature constantly going on.

On many occasions, as when the heat of the sun alone would tend to raise the temperature to a sufficient height, the hot water may be given only as a means of supplying air—keeping the whole of the front panel out entirely, and only closing it soon enough to retain a degree of the warm moist atmosphere with which the case gets filled.

It need not be feared on these occasions that the air will become too dry. The entire shelter afforded on three sides, as well as at the top, will suffice to prevent this happening. When a whole panel is thus removed, I think it should be the front one—not the top. Though when only a little air is left on I have found it very desirable that this should be at the top, raising the edge a little by the pin provided. And it is an unqualified certainty in the management of these cases that the more air that can be given at one side or at the top (never in two places together) without reducing the heat below

what is absolutely necessary, the healthier, and the better, and the more luxuriant will the plants be in their growth.

I very often myself, after keeping the front panel entirely out all day, leave the pin up to its full extent, at night, when it is put in; but numerous modifications of these plans must be tried, no doubt, the circumstances varying as much as the weather and the kinds of plants.

When the case is covered at night, as it should always be in cold weather, with a thick woollen covering, the air may still be left on below it. Any arrangement also by which a slight stratum of air is left between the woollen cover and the case is useful; the atmospheric air being, as all the readers of this Journal must be well aware, a remarkably good nonconducting body. The thing is so essential that I must once more repeat that, whether by day or night, whether in hot weather or cold, the more air that can be given consistently with maintaining the degree of heat and moisture requisite for the plants the better assuredly they will grow and thrive. A small thermometer hung up to face the glass about the middle of the case will give information as to the heat, without its being necessary to take out or unclosethe glass,—which taking out the glass is sometimes most undesirable, as, for instance, on a very cold winter's night, when the warm air within has to be preserved most carefully.

The moisture is not by any means a difficulty; the sand being kept just not dry, it is impossible to have warmth, especially from the bottom of the case, without some vapour rising.

Even when the case is open at the side there is generally enough moistness remaining in the air, as in a place so entirely confined and sheltered there is no rapid circulation. The only precaution necessary is not to open the side of the case standing next to and immediately in front of an open window on a hot, much less on a breezy day. At all times, indeed, it is a thing as well avoided, and for residents in London, Brighton, Edinburgh, Glasgow, Leeds, or Birmingham, who may use these cases, keeping the open side away from the open window will be always preferable. I name these towns because I know each to be noted for the love of flowers that reigns there, and in some because of smoke, in Edinburgh because of the keen winds to which the eastern coast is so generally liable, and in Brighton and all other coast towns because of the salt breezes which are so hurtful to vegetation, I feel convinced that my caution will not be unneeded.

I think it is well to mention that in the Plant Case exhibited at Kensington Gore one or two plants in blossom were added which would properly belong to the greenhouse temperature. The Camellias and Heaths last, however, very well in the warmer cases when forced forward much, and it must be remembered that a strongly-forced plant, even though a hardy Rose or Deutzia, is for the time as tender as its exotic neighbours.—E. A. M.

(To be continued.)

CINERARIAS AND PASSIFLORA SEEDLINGS IN A SITTING-ROOM.

SOWING PANSY SEED.

I HAVE about eighteen seedling Cinerarias which I raised in June; I have no place to keep them in but a sitting-room, which I have brought them into every night for the last fortnight. During the day I keep them at the north end of the house on a stage. We burn gas in the room at night, and since I brought them into a room several of the plants have begun to curl in the leaf (inwards). Do you think it is the gas that is the cause of it? They were fine beautiful plants before. They are in sixteen-sized pots and coming into bloom.

I have several seedling plants of *Passiflora cœrulea* raised in June. I have them in pots, and keep them in the same place as the Cinerarias. Will they flower next year if I get them forward in spring? I have one plant of this *Passiflora* that I

raised in the spring of 1860, I have it planted against a south-east wall in rich garden soil; it grew some 8 feet or 10 feet high this summer, but did not flower. I have cut it back within about 1 foot of the ground and intend to protect it during winter with mats. Have I done right? The district is about ten miles south of York.

What would be the best time to sow Pansy seed to have a good bloom by the middle of August?—C. E. W.

[Your Cinerarias may suffer from the gas; but more likely from the dryness of the room. Without seeing the plants, if they are showing bloom, we think you would have more success with them in half-the-sized pots—that is, thirty-two instead of sixteen. We would recommend you placing your plants in the sitting-room window during the day, and the pots to stand in saucers, with moss in the bottom of the saucers, and to keep that moss a little moist; and, then, if you do not mind a little labour, move the pots at night where they would be safe from frost, and receive little artificial heat of any kind.

It is not likely that the *Passifloras* will bloom until 1863; but it is possible. The plant you have now cut down, if protected from frost, will give you a good shoot next season. We would only encourage one. Next autumn we would have it 8 feet or 10 feet high, and either protect it so, or roll it in a mat, and protect the roots too. The year following the shoots that come from that stem may be expected to bloom, and you will have fresh flowering shoots every year by pruning back to within two buds or so of the same stem.

Sow the Pansy seed in your room in March, harden off and transplant out of doors in April and May: this will give you stronger plants than sowing out of doors at once.]

VISITS TO SOME OF THE FRENCH NURSERIES.—No. 3.

VERSAILLES.

THE inhabitants of this environ of Paris never can imagine that anything but a desire to see its grand château could ever bring an Englishman to their terminus; and even if I could have hidden my country, the portly presence of my excellent companion is so unmistakably English that we were at once proclaimed as such, and proffers of assistance of all sorts were freely made to us as we *debouched* from the railway, to the infinite disgust of all concerned. However, we declined the honour; on that day the château had no charm for us; its long galleries remained unvisited, and its gardens and orangeries unnoticed. We were bent, at least my friend was, on business; and I followed in his wake—my eyes and ears were to be employed while he discussed the weightier matters of business. We were bent on two visits; but, as one of the friends was absent, we had to take it on a second day. I shall, however, include them both in the one notice. One (M. Rémont) is a gentleman but little known in England, though an ardent admirer of her liberty and laws; the other whom every-body knows, by name at least, M. Truffaut, the originator of those tasselled or French Asters, which have been such a boon to our gardens and such an ornament to our autumnal exhibitions. The nursery of

MONSIEUR RÉMONT

is of a very extensive character, his grounds comprising nearly 400 acres, and containing every kind of forest tree suitable for France, and a fine collection of Conifers. Everything is grown in very large quantities, inasmuch as he is extensively employed in planting the various lines of railways which now traverse France in all directions. The embankments are thickly planted, especially with the various species of *Acacias*. Some idea of the extent of his operations may be attained from the single fact that he has planted nearly 400,000 trees in the Bois de Boulogne alone. This year he has been peculiarly busy, and in one sense unhappily so, for we were here introduced to the ravages of the terrible "ver blanc," or grub of the cockchafer, which has often-times caused devastation in this country, but whose ravages I had never before seen to such an extent. Whole plantations of *Wellingtonias*, for instance, were decimated by them, the wretches with their very powerful mandibles completely barking all the larger roots and cutting off the smaller ones, so that plants that were looking healthy and vigorous a few days before all at once turn yellow and wither away. It was the same with other

species, and in the case of softer herbaceous plants the root is completely eaten through. Thus Truffaut has lost thousands of his *Asters* this year, and I saw in their ground, in about half-a-dozen yards where the *Gledizies* were being taken up, a large pot—about a 16—filled with the nasty ugly-looking vermin. The neighbouring forests attract them, and then, when the ground is broken up and in good condition, they attack it, while the absurd mania in France for killing everything in the shape of a “petit oiseau” for the sake of the table has deprived them of a very useful auxiliary in getting rid of the grubs of this and various other hurtful species.

Talking of this, I saw in Paris a curious-looking piece of mechanism which turned a piece of wood full of various coloured glasses, and on inquiry found it was used for “catching larks,” this being said to attract their attention, to such an extent do they carry these bird-killing propensities.

Another tree cultivated by the million is the *Ailanthus glandulosa*, hitherto rendered somewhat more notorious by its being the tree which the new species of silkworm feeds upon, and about which some of the French savans, who wildly premise everything, have been so enthusiastic. Unfortunately, at present, it seems very much in the condition of the Irishman's horse, when caught, good for nothing: for though it is hardy, lives and spins its cocoon in the open air, at least in France, no satisfactory method has yet been obtained for winding off the silk. I have one lying before me now, and a more unpromising-looking cocoon I never saw. However, French ingenuity may overcome it as well as Chinese, unless indeed we get the information from them. Monsieur Rémont has just taken a new élan, with a large quantity of the finest land in the neighbourhood of Versailles, and he is now very busy in getting some portion of it ready for nursery stock.

MONSIEUR TRUFFAUT'S

is an establishment of the very opposite description. His ground is small, and he cultivates mainly a few things, with some of which he supplies regularly the Paris markets. Of *Anemyllids* he has, I suppose, the finest collection in the world. He has hybridised them very extensively, and has now upwards of 400 varieties. They are grown in beds under glass, and some of them are exceedingly fine both as to size and colour. One variety, *acuminata*, had upwards (this season) of sixteen expanded blooms on it at the same time. When this long pit, with upwards of 2000 bulbs, is in full bloom, it must be a very fine sight. Another bulb which he very largely cultivates is the Persian *Cyclamen*. This is grown from seed; the seedling plants are pricked out into frames filled with suitable compost, and protected from the frost. They are, when the bulbs obtain a fitting size, taken up and potted, and are done so well that he can sell them for about 5*l.* and 6*l.* each, the larger-sized bulbs at 10*l.* and 1*5*.. They are a very favourite flower, and deservedly so with the Parisians, as they stand the atmosphere of a sitting-room well, continuously bloom, and some of them at least, are very fragrant. Mons. Truffaut also grows *Rhododendrons* much for the same purpose. We do not find anything like the extensive grounds of Bagshot and Knapp Hill; but he cultivates such varieties as are showy in character and free-blooming, and these, as soon as they attain sufficient size, are also sent off to the Paris markets. The flower, however, with which his name is most associated is, as I have said, the tasseled or French *Aster*. The whole of his seed is sent to Vilmorin, Andrieux & Co., and by them distributed; but by far the larger proportion of this seed is now obtained in Germany, as most purchasers know from the curious-looking packets in which they receive them. They evince great care in the selection, as anybody may very well testify from the excessive truthfulness with which they come. They, moreover, select the largest and most vigorous-looking flowers and seed them, and do not leave many on each plant. I noticed also a good number of a pretty bulb allied to the *Tigridias*, *Rigidella orthontha*, by no means new, but I cannot recollect having seen it flowering in England; and having a penchant for bulbs, it struck me as likely to be a nice thing. The *Camellias* also were in very good order, and the whole grounds very neatly kept.

I heard here the same complaint that I have noticed in Paris—the decline of amateur gardening in France. In the suburban villas, where in our own country this taste so manifests itself, one notices, all around Paris either neglect or else the space occupied with vegetables and shrubs. Doubtless the habits of the French have much to say to it; here has little charms for them—the Café and the Boulevards far more. The French

paternfamilias cares but little for the exterior of his villa, and would probably consider it great extravagance to expend anything upon it. Such a state of things would be fatal to horticulture here, as I have often heard sellers of flowers say their best customers are amongst this class. We are fond of copying our lively neighbours; but I am sure all readers of THE JOURNAL OF HORTICULTURE will wish it may be long ere we copy them in this.

Thanks to Mr. Beaton for his notice of Phascelus; but is it to be given up? If increased attention has conquered Bougainvillea and Disa, why not Phascelus? Let Mr. Leach try his hand at it.—D., Deal.

ADORNMENTS AT THE ROYAL HORTICULTURAL SOCIETY'S GARDEN.

OVER the entrance to the new gardens at Kensington are the names of six great botanists. Would not the name of the great Loudon (who did more for gardening and gardeners than the whole family of botanists), or even of good old Abercrombie, be more worthy of such a position in a horticultural garden than any of them? What are the names of these botanists there for? If, as Mr. Robson has shown, horticulture is scarcely to be found there, botany is in much greater obscurity.—WILLIAM ROBINSON.

[We quite agree with our correspondent that the names of some of our most celebrated deceased gardeners would be more appropriate at the Kensington Gore Gardens, than those of botanists. At the same time we would not exclude these. Gardening is too much indebted to botany not to admit memorials of its chiefs among her records.

The names of Miller, Abercrombie, Loudon, and of a few other leaders among our departed gardeners ought to be there, and especially that of Mr. Knight, the Society's first President, who so pre-eminently advanced horticulture by his combination of “Practice with Science.”

We should like to have busts of them all placed in the conservatory. Whilst on the subject of statues, we must express our hope that those most offensive figures of Venus and the Satyr will be removed from the colonnade, and banished from the garden. It is a group indelicate; is out of all proportion to the mole-hill of rockwork on which it is placed; and would be misplaced in any part of any garden—superlatively so, therefore, in a garden which ought to be a model of good taste.—EDS. J. OF H.]

SHORT'S PLAN FOR AVOIDING THE POTATO DISEASE.

OUR experiment of Short's plan for the prevention of the Potato disease was a failure. We began covering the ridges the last week in July; the spit of soil put on most effectually sealed up the tubers; when the dry weather of August came they could reap no benefit from it. They were taken up about the middle of September, neither so fine nor so clean, with many more diseased ones, as the produce of a piece left uncovered.

July brought the disease in our neighbourhood, and fears were many that the Potato crop was a doomed one, but August came and altered the aspect of affairs, and the crop is an average one.—N. H. P.

OUR CULTIVATED NATIVE PLANTS.

GARDENERS AT THE ROYAL HORTICULTURAL SHOW.

I AM very fond of British plants, and am a successful grower of the Lady's Slipper, as you would see in last volume of the Journal. I am now trying to grow successfully the *Primula farinosa*. It grows best in meadows with a boggy or wet soil lying on limestone, in open situations, where it must get baked at times, drowned at others. I also have Balsam (*Impatiens Noli-me-tangere*), it is indigenous here.

Allow me to suggest that some notice ought to be taken of the very dirty dress and appearance of some of the gardeners (apparently) who were at the Royal Horticultural Show last Wednesday. I was there some hours, and was disgusted to see some unclean—i.e., unwashed and unbrushed fellows elbowing amongst the ladies' nice dresses. I am a great advocate for admitting gardeners at the best time to all shows, as it clears

their minds of a great deal of self-opinion, and I like them to hear the remarks made by ladies and other visitors of high degree; but let them show that they appreciate that privilege by at least brushing up their garments, even if they be threadbare; and soap and water surely are cheap enough. In this part of the world (Lancashire) gardeners trim themselves up, and would have felt a-lamed to have gone in as dirty condition as I saw two or three, who evidently might be good gardeners by the way they criticised the Chrysanthemums.—W.

CHEVREUIL'S MODE OF GROWING MUSHROOMS.

I HAVE copied from the *London Review* the enclosed plan for increasing the growth of Mushrooms. Would you be so kind as to explain the two places I have underlined? By the term "plaster," is lime plaster meant, or is it wet, muddy earth?

By the Latin term it is meant something adhering to the white stem of the Mushroom, and which can only be detected by a magnifying glass?—J. HUDSON.

"Mr. Chevreuil has recently exhibited to the Academy of Sciences the result of a plan adopted by Dr. Labourette for obtaining Mushrooms, in the shape of an enormous mass of these fungi weighing 8 lbs. on a single stem, which has sprung up in the short space of six days. The plan of culture is as follows:—On a piece of marshy ground he spreads sand or gravel to the depth of 7 inches or 8 inches, on this he forms a *second bed of plaster* about 3 inches thick, and spreads over this two grammes of nitrate of potash to the square yard. From the white part of the Mushroom he extracts by means of a magnifier, the most developed mycelium, and sows it on the surface of the bed. The germination soon commences, and the vegetation becomes very active, and in a few days the bed is covered with monstrous Mushrooms. The action of the saltpetre lasts for six years, and the Mushrooms as rich in nitrogen as the best food, form a very substantial nourishment."

[We do not know what the "plaster" is. There must have been some preceding statement which our excellent contemporary has omitted. The Latin term "mycelium," is the botanical name of the spawn or white filaments which give birth to the Mushrooms.—Eds. J. of H.]

ENTOMOLOGICAL SOCIETY'S MEETING.

The October Meeting of the Entomological Society was held on the 7th ult., and was presided over by J. Lubbock, Esq., F.R.S.

Among the donations to the library received since the last Meeting, were the publications of the Royal and Zoological Societies, the Philosophical Society of Liverpool, the Smithsonian Institute, and the Royal Society of Munich.

Mr. Pascoe, on his return from a twelvemonth's residence on the Continent, exhibited a very interesting series of Coleopterous insects collected by himself in the south of France, and amongst which were two new species of Blind Beetles, *Anophthalmus* Raymond, taken in the cavern of a monastic establishment near Hyeres, and an *Anilhus*, found under very large blocks of stone deeply embedded in the earth.

Mr. Waring exhibited some beautiful specimens of Moths, captured in Inverness-shire during the past summer, including *Noctua sobrina* and *Ypsolophus juniperellus*. And Mr. Miller a remarkable variety of, or possibly a new species nearly allied to *Ephyra undularia*, reared from a caterpillar found near London.

Professor Westwood exhibited a specimen of *Myrmecolax* Nietneri, a remarkable parasitic insect belonging to the order Strepsiptera, from Ceylon, which he had extracted from the body of a Worker Ant sent to him by Mr. Nietner. A specimen had been previously received and described; but it had been almost entirely destroyed by Mites on its passage to this country. He also exhibited specimens of the eggs and larvae of two Dipterous insects belonging to the genera *Vohucella* and *Anthomyia*, parasitic in Ants' nests. The eggs of the former insect had been exhibited at a previous Meeting, affixed to the outer covering of the Wasp's nest, and had been mistaken for the cocoons of some minute insect. Likewise specimens of the larvae of the Social Moth, *Liethya sociella*, with a mass of its cocoons, found parasitic in the nest of the Humble Bee, *Bombus*

sylostriis, which had been communicated to him by Mr. S. Stone, of Brightonampton. He also read descriptions of some new exotic species of Stag Beetles, Lucanidae, from the collections of Major Parry and Mr. Bakewell.

Dr. Wallace gave an account of the contents of an old cabinet of Lepidopterous insects belonging to Mr. Baker, of Suffolk. It was interesting, as containing amongst the Butterflies specimens of *Apollo*, *Podalirius*, *Vergara*, *Chryxus*, and *Acis*, of which the localities were recorded; also, various very rare Moths, including *Sphinx celano*, *Eulepia grammica*, *Plusia illustris*, &c. Some of these species had been struck out of the British lists by recent Lepidopterists, but Dr. Wallace thought it possible that they had really been captured in the localities indicated, and that they might reappear as other species had done; which had been too summarily rejected from the lists.

Mr. Stainton read a paper on the nomenclature of a small Moth, *Laverna langiella*. And Mr. Waterhouse communicated an memoir on the synonymy of three species of British Coleoptera, belonging to the genera *Ilomla* ta (*H. subterranea*), *Aploglossa* (*A. rufipennis*), and *Ceutorhynchus uliginosus*.

Dr. Knaggs exhibited various larvae of the Moths forming the genus *Eupithecia*, some of which were singularly infested with parasites belonging to the family *Telmomuridae*. These had been transformed to the pupa state, enclosed in cocoons, leaving only the thin semi-transparent skin of the caterpillar distended by these parasitic cocoons.

CONSTRUCTION AND MANAGEMENT OF COLD PITS.

You will greatly oblige me if you will give me a few plain and minute directions as to the making and management of a cold pit—i. e., a pit to winter my cuttings, Calceolarias, &c., in. I have an ordinary two-light frame. I am quite a beginner in gardening, and know next to nothing of the subject. I find, however, that my man knows even less. Such information as I ask for would, I think, be acceptable to many of your subscribers just now?—ALPHA.

[There has been so much said on that subject lately, and the relative importance of sinking them and building them on the surface, and the great inferiority of pits to small houses where pleasure and comfort are considerations, that I might well refer you to a long index, not forgetting the interesting paper on this subject a week ago by our friend Mr. Beaton, who, I have no doubt, will make the plan answer admirably, though it might be a little puzzling at first to young beginners like "ALPHA," and his, no doubt, anxious assistant. I am afraid that, be plain and simple as we will, we do not at all times make things easy enough to some of our inquiring correspondents, for it is impossible to make gardening operations as regular as measuring a yard of cloth, or writing out a summons or an indictment—in other words, nothing that we can say can ever render gardening successful without the constant thoughtfulness and unremitting attention of the gardener. In the case, especially, of all plants that will not stand the vicissitudes of our climate, the want of attention for an hour may wreck all the labour of the season.

So far as Calceolarias are concerned, there could be no place better for keeping them in during winter than a two-light box or frame, provided by secure covering in frosty weather, as all bedding Calceolarias do best afterwards, if they never know what fire heat is. In all fine sunny weather when the air is mild, air should be given freely, even to the sliding off the sashes. In sunny frosty days when the air is cold and above freezing in the shade, give air at the back only, by tilting up the sashes 2 inches or 3 inches and shutting up early in the afternoon. In dull muggy weather if the thermometer averages 10°, give air top and bottom by raising the sashes an inch or two. This will let air go right over the plants, and yet prevent rain falling on them. These same rules will apply to all plants kept in cold pits, for a frame with sound wood from 1½ inch to 2 inches thick, will about keep out as much frost as a nine-inch wall; but most other plants required for bedding, will require even more care to prevent damping as well as to be secure from frost, and this damping is the great enemy to all beginners and becomes a difficulty, when, as last season, it would not be safe to uncover for a month. To avoid this damping, whatever the material used for keeping out frost, it would be important to have a waterproof covering to throw the rains past the frame, or pit, in frosty sleety weather, as even the nonconducting properties of a covering, be

it mats, hay, straw, &c., are much impaired whenever they become wet.

Now, as to pits, sunk or just placed on the surface like a frame, bricks merely being substituted for wood, the circumstances of the case must determine which is best. For instance, in a cold exposed place, and where the subsoil can be rendered dry easily, a sunk pit like *fig. 1* would be the best—say $5\frac{1}{2}$ feet

high at back, and $3\frac{1}{2}$ feet in front, the pit being 2 feet below the ground level. This will give plenty of convenience for covering the glass in frosty weather, and also moving the sashes back and front. The walls of such a pit might be solid 9 inches, but I should prefer them to be 14 inches hollow. With such hollow walls it would take a long-continued severe frost to go through the walls; whilst a few days' frost ranging from 10° to 20° below the freezing-point, will penetrate a nine-inch wall; hence, I have known plants ruined in a cold pit with abundance of covering over the glass to keep out the frost, just because the brick wall was not thought about. In a hollow wall the enclosed air prevents the conduction of heat, and, consequently, such a wall will be also colder in summer. Taller plants could also be grown in such a pit, and receive more light than in one equally deep built on the surface. In building, a ledge should be left out of 2 inches or 3 inches, back and front—say 20 inches or 2 feet from the bottom, for receiving a platform of boards, and there most plants would be kept safer in winter than standing on an earthen floor, as there would always be air beneath them as well as above them, and that body of air would prevent such a pit from being either so suddenly heated, or so suddenly cooled as a shallower one. Of course, it would be a great advantage if such a pit could be heated by hot-water pipes or a flue, but then it ceases to be a cold pit. If the pit is not more than 30 feet to 40 feet in length, a small flue would be the easiest and cheapest mode of heating it, and the flue could be built in the wall, leaving an open space over the top to let the heat freely into the pit, and if there is an open space, however small, shut in between the outside of the flue and the outside wall, very little of the heat will find its way outside. If the water that falls on the glass is of consequence, then the cheapest plan would be to make a groove channel in the wall-plate; but if the water is of no consequence, then we would have the wall-plate to extend beyond the wall a couple of inches, and on the lower side, half an inch from the front, cut a groove a quarter of an inch wide and the same in depth. This will prevent the water trickling from the wall-plate to the wall, and loosening the binding-lime there. We recently saw some fine pits the other day that had none of this weather-groove. Most of the water will thus be thrown past the wall, but to make sure we would paint the front wall with tar, and raising the ground to the wall in a slope for a yard or 4 feet, we would place a layer of tan there, one-twelfth or one-eighth of an inch thick, and then covered with gravel and rolled firm, no water would either get through the wall or the ground near it.

All that has been said as to spouts and walls will equally apply to *fig. 2*, representing a pit built on the surface, where it

would be unsuitable to go down, unless from water and other causes to fire worse. This we suppose to be 3 feet at back and 1 foot 9 inches in front above the surface level. We have also supposed a wall of 9 inches, but that we also would prefer to be

hollow. If solid the walls must be protected with straw whenever there is a continuance of frost above 8° or 10° below freezing-point. Such a pit would cost much less, but must be more carefully attended to in giving air and securing from frost, and extra care to avoid damping. To help in the latter case, the plants could be moved in fine days in winter, the damp bottom scaped off, and 2 inches or 3 inches laid on of dry ashes and lime, which would also sweeten the atmosphere of the pit. Under such an arrangement the plants, except *Calceolarias*, should be kept dry rather than otherwise all the winter, and when a plant, or a pot of cuttings, shows any signs of distress from drought, the plant or pot should be lifted out and watered, and only replaced after all extra moisture has drained away.

The great object to attempt with such a pit is to keep the plants, and to grow them as little as possible during the winter. For this purpose it would be desirable to have the plants, cuttings, &c., well established in their pots, and well hardened off before being placed in the pit, then to have as much air as possible when the outside thermometer ranged from 38° to 40° , but not a drop of rain on any account; a little air at back at all times during the day if the outside thermometer was above 35° ; more in fine days, and especially when mild and sunny; but in hot sun and frosty air to give merely a little at the top, and we prefer a little shading if necessary, to a great amount of frosty air, which dries and burns up such plants numerically.

Some covering must be requisite to keep frost out. Nothing is better than calico next the glass to keep all clean, then mats, or hay or straw above, and then a waterproof covering sufficiently wide to go beyond the width of the frame on all sides. If the air is dry enough within, and the temperature only a few degrees above freezing, the plants may be shut up for a month in bad weather and be none the worse for it. They will suffer as little as grass suddenly covered with a foot or 18 inches of snow, which keeps it from the light for a month. The tarring of the walls and also making the ground waterproof in front of such a pit, so that the rains shall not soak back inside, will render the management more easy. In continued frosts, above 10° especially, the walls should be protected with straw fastened against them. With all this care any bedding plants that are generally used may be kept in such a pit.

In severe winters, the continued care and the difficulty and expense in procuring covering, and the time required in turning it over in frosty weather, so as to break the line of conduction of the heat escaping, or the frost entering, which is much the same thing. The time taken up in doing so, and the chance, even with the greatest care, of smashing some glass now and then, added to the discomfort of not being able to see the plants at all times, and the diminution of pleasure from not being able in all weathers to attend to their wants, have led to a strong desire to have some cheap structure, where such objections would not be found, and where a little fire heat could be chiefly given. Now, the cheapest of all modes of heating a small house—say, 9 feet by 20 feet or 30 feet, would be an Arnott's brick stove inside the house, or a portable iron stove, which, however, we do not like so well, and a small portable boiler might also be used; but in the case of those great numbers who would rather have the fire outside than inside the house, I would recommend such a house as shown in *fig. 3*.

Width 9 feet, height to apex 7 feet, height of side walls 3 feet, openings in these side walls for air 1 foot by 18 inches every 4 feet, ledge left out in side walls to receive the ends of flooring for pots, the other side being supported by posts

at the pathway, and a plank some 4 inches square with a notch in it to receive the other ends of the boards or spars for pit platform. Underneath this platform there will be room for stowing Dahlias, Salvias, Fuchsias, old roots of Scarlet Geraniums, &c. Roof all fixed, rafter sash-bars 3 inches by $1\frac{1}{2}$ inch, placed so as to receive squares 18 inches wide by 12 inches deep, and two squares at top every third row made in a frame, and made to slide or open on pivots. A cross-bar every 6 feet across from rafter to rafter, and a shelf in the middle over the pathway, if deemed advisable, for small plants. The space beneath the platform, and also the sides of the pathway would hold many things when first potted before they began to grow, and were thus able to stand the sun on the platform without any shading.

We have represented this house as being heated by a flue sunk in the middle of the house, but free of the earth all round. If the floor were tiled, the same tiles could go over the top of the flue, leaving the open spaces at the sides so as to secure more heat, or if the floor were earth or gravel, the top of the flue could form the path, or a sparred gangway could go over it. Either of the two first would be the cheapest. A flue on the same principle is shown in *fig. 4*; but to save expense the bottom is placed on the ground, and slates or tiles placed diagonally at the sides to prevent the soil coming against it, and thus let the heat ascend from sides as well as tops. This flue may receive a wide-enough cover to form the walk, or may be covered over like the rest of the floor, if tiled.

Supposing the doorway was at one end, or you had a doorway at each end, so that you could go right through the house, then the stovehole should be sunk a little at the side of the doorway, the flue turned a little until it got to the centre beneath the pathway, and then turn a little at the other ends so as to avoid the doorway, if there is one, and go into a small chimney there. Such a flue in a length of 30 feet might rise from end to end some 2 inches or 3 inches, and to draw well the bottom of the flue ought to be from 15 inches to 18 inches above the fire-bars, so that for such a small fireplace as would suit this flue, you would have to sink a stovehole from 3 feet to 3 feet 6 inches below the ground level, and the small hole could be covered with a neat wooden flap.

But, now, supposing that your soil is so bothered with springs and swamps that you could not expect such a hole to be made without retaining in winter 6 inches or 12 inches of water, then all you have to do is to sink all that less, and take your flue along above the ground level, beneath the flower platform, instead of in the middle of the house. This house we would advise for a warm sheltered spot, and we think that in a short time it will prove cheaper than a pit, as though much more glass will be wanted, the fixed roof will otherwise cost much less than the sliding sashes.

Fig. 4 is a form of house that we would recommend for an exposed place, and where even a little fuel would be a consideration; with the same, back wall $5\frac{1}{2}$ feet, front wall $2\frac{1}{2}$ feet to 3 feet, sash-bars the same; but if the house were 30 feet long we would have two slight pillars in the middle, 10 feet apart, and an iron bar along the roof. The short-hipped roof at back might be glass, one-third of it moveable; or, if warmth were a great object, it could be wood, and be painted a light colour inside, and a ventilator placed in it all the length. The front ventilator we would secure by openings in the front wall, and slides. If the house were to be filled with small plants, brackets

for shelves could be left in the back walls. The same principle would apply to the flues; and if a little more expense were no object, hot water might be substituted. Such a house with a fixed roof would cost little more than a pit with moveable sashes, and there could be no comparison of the pleasure it would afford, and that, too, ultimately in the most economical manner.

Now for the management of such a house. In summer, unless in boisterous weather, all the ventilators and doors may remain open for months; in winter the tenderest plants could be placed nearest the furnace. If the house were from 30 feet to 40 feet long, it would be better to make two divisions, and place Calceolarias at the farthest end, then Petunias, then Verbenas, and so on, keeping fine Pelargoniums, &c. at the warmest end. The admission of air will always regulate the temperature. Firing should not be given in frost to raise the temperature more than to 38° to 45° ; never above the latter. We have made no allowance for moist heat, because from the soil in the pots, and from the floor, sufficient moisture will, in general, be obtained; but if in continued frosty weather the air should become too dry, that is easily remedied by syringing the platform, or damping the floor and walls. The same care must be attended to in giving air as in a pit; but here comes in the advantage of a place to which heat can be applied; you can give just a little air at the top every day, just to sweeten the air in the house; and in cold muggy weather you can put on a little fire, which will enable you to give such an amount of air as will make a little breeze in the house, and even cause the cold fogs to disperse, by changing visible clouds into invisible vapour.

Like everything else, the heating must not be abused; and too much heat is almost as great an evil as too much cold, but a little attention will soon enable a careful man to regulate all that, and also permit him to go to bed at night without being troubled with nightmare visions about Mr. Frost riding away with his most favoured plants.

In one word then, I do not despise pits sunk in the ground or built on the surface—I could use many more than I have, and be on the look-out for more then; but in no case are they so valuable as small houses, which may be considered pits with some simple mode of heating them. After covering a couple of yards from the surface, nine-inch drain-tiles make a good flue; and the mode of fixing and managing them has frequently been described:—of course, they must neither be walked on nor kicked against.—R. FISK.]

FERNS IN GLASS CASES.

It is very gratifying to observe the study of our beautiful native Ferns becoming so popular, particularly amongst lady

amateurs. No study can possibly be more interesting, I may say fascinating, when entered into *con amore*. Now, as I do not

doubt but that there are many who are partial to the pursuit who have no garden in which to plant them, yet would like to have a few, at least, of their favourites growing under their immediate inspection, I will endeavour to describe a method of preparing a glass case, by which they may succeed in growing several varieties in a very interesting manner.

I should prefer a stand similar to that represented in the engraving; it should have a diameter of 3 feet, but 1 ss would of course suffice, in cases where that may be thought too large. The glass case should be made to fit exactly to the inside of the stand, and should have the framework formed of stout brass bars, well secured to a strong rim of zinc round the bottom. A department on each side should be made to open, care being taken that these openings are made as nearly air-tight as may be, and a few hooks should be securely fastened to the bars in the

upper part of the dome, by which to suspend small plants in pots. The stand should be fixed nearly to a level with the rim with broken potsherd or sandstone, or any rubby porous material. Over this should be laid a small stratum of sand, to make a very level surface. In the centre, on this level surface, place a four-sided cone of zinc, about 16 inches in height, with a saucer at the top, and having some strong pieces, of about 2 inches square, well fastened to and projecting from the sides. Next commence around the base of the cone, and place angular pieces of sandstone of about five or six pounds weight each, and pile up thus completely over the cone. The projecting pieces will assist in retaining the stones in position; and a most important point to be observed is, that every stone must be laid perfectly firm from bottom to top, as the plants will not flourish on a moveable stone. This may be insured by the use of a little cement, as the operation proceeds; but I have also made use of small, flexible wire, passed several times round the mass, for the same purpose. The interstices between the stones may be filled with some nice fibry loam, sandy, soft, and unctuous to the touch. The Ferns are to be planted in these interstices, taking care to make them firm in position.

With regard to sorts, although the smaller-growing varieties are undoubtedly the best adapted for such a case or vase, yet I have used seedling plants of the larger kinds, and these can be removed when they get too large. A case of the size proposed would hold a plant of nearly every British species; but if this were attempted, it would, of course, more frequently require rearranging. The spaces between the Ferns may be appropriately filled up with various Mosses, Marchantias, Jungermannias, Lycopodiums, &c., so that the whole of the miniature rock may be covered with vegetation, and present a green surface. A large plant of Lycopodium umbrosum, on the summit of the pile, would look beautiful; and small pots of the trailing Lycopodiums may be suspended from the hooks in the upper part of the dome. Previous to the stones being placed, they ought to be soaked for a few hours in water. The saucer at the top of the cone should also be filled with water, and the roots of each plant dipped in water as the planting proceeds. When all is completed, sprinkle the whole with water through a fine watering-pot rose, but avoid deluging it; this watering may be repeated from time to time through the doors, but the case being almost air-tight, and evaporation being prevented, water will not often be necessary. The sandstone I have mentioned is a soft ferruginous stone, found in many parts of Kent, and so congenial to the growth of Ferns, that their seeds or spores falling on the shady, moist sides of the rocks composed of it, germinate by thousands.—JOHN COX, Gardener to W. Wells, Esq., Redleaf.

[Those who may be interested in growing the most elegant and choice of the British Ferns in glazed cases, such as Mr. Cox has described, will find the following selected sorts well suited for the purpose. Most of the sorts mentioned are to be obtained without much difficulty:—

Polypodium dryopteris.—Bright green, delicate, and pretty; fronds nearly triangular in outline, annual; height 4 inches to 8 inches; caudex creeping.

Polypodium vulgare canaliculata.—Evergreen; fronds broadly lance-shaped, with a kind of fringed margin; height 6 inches to 10 inches; caudex creeping.

Asplenium crispum.—Very elegant, parsley-like; fronds almost

triangular in outline, annual; height 4 inches to 6 inches; caudex tufted.

Lastrea oleropteris.—A sweet-scented Fern; fronds lance-shaped in outline, annual; height 1½ foot to 2 feet or 3 feet; caudex tufted.

Lastrea filix-ferina.—One of the commonest, but a very elegant Fern; fronds lance-shaped in outline, annual; height 2 feet to 3 feet; caudex tufted.

Lastrea rigida.—Very elegant; fronds lance-shaped in outline, annual; height 1 foot to 2 feet; caudex tufted.

Lastrea Fenisicii.—Very elegant and compound; fronds nearly triangular in outline, annual; height 1 foot to 2 feet; caudex tufted.

Polystichum lancheitis.—Very rigid and holly-like, evergreen; fronds narrowly lance-shaped in outline; height 6 inches to 1 foot; caudex tufted.

Polystichum angulare.—Very elegant and graceful, sub-evergreen; fronds broadly lance-shaped, drooping; height 2 feet to 3 feet; caudex tufted.

Cystopteris fragilis.—Very delicate and pretty; fronds lance-shaped in outline, annual; height 6 inches to 10 inches; caudex tufted. There are several varieties, all of which are very interesting.

Althium filix-ferina.—The Lady Fern; one of the most elegant; fronds lance-shaped in outline, drooping, annual; height 1 foot to 3 feet; caudex tufted. There are several varieties, of which one is like a dwarf-curled parsley, but the most elegant has tasselled pinnae.

Asplenium adnatum-nigrum.—Evergreen and glossy; fronds elongate, triangular in outline; height 6 inches to 1 foot; caudex tufted.

Asplenium marinum.—Evergreen and glossy, dense in its habit; fronds lance-shaped in outline; height 6 inches to 10 inches; caudex tufted.

Asplenium trichomanes.—Evergreen, with black wiry stalks; fronds very narrow; height about 6 inches; caudex tufted.

Ceterach officinarum.—Evergreen; fronds lance-shaped in outline, green above, scaly beneath; height about 4 inches; caudex tufted.

Scopolopodium vulgare crispum.—Evergreen and very distinct in appearance; fronds narrow lance-shaped, undivided, the margin crisped; height 8 inches to 1 foot; caudex tufted.

Adiantum capillus-Veneris.—Evergreen, and very elegant and distinct; fronds irregular, but somewhat ovate in outline, the little wedge-shaped leaflets attached by fine wiry stalks; height about 6 inches; caudex tufted.

Blechnum spicatum.—A very elegant and distinct Fern; fronds narrowly lance-shaped in outline, annual; height 1 foot or more; caudex tufted.

Trichomanes radicans.—Delicately transparent, and very beautiful when seen in a vigorous state; fronds either triangular-ovate or lance-shaped, drooping; height 6 inches; caudex creeping.

Hymenophyllum tubridigense, and H. Wilsoni (multilaterale).—Moss-like, forming dense matted masses, deep dull green, and uninteresting at first sight, but very beautiful on minute examination.

Osmunda regalis.—Almost too large for a case, for which, however, small plants may be used; fronds lance-shaped in outline, annual, diff'ring from all the preceding in bearing their inflorescence in collected masses, occupying the whole apex of the fronds; height 2 feet to 6 feet, or more; caudex tufted.—M.]
—(Gardener's Magazine of Botany.)

LILIPUTIAN DAHLIAS.

I HAVE grown Liliputian Dahlias during the last two years. The flowers are all you describe, but the plants grow nearly as high as the large Dahlia. I put them as a border to White Zinnia in the centre, which they quite overtopped, and as the bed was intended to match a bed of Asters, it was a disappointment. Can I do anything next year to make them a grow more dwarf?—HANLEY.

[We sent your note to Messrs. Henderson, of the Wellington Royal Nursery, and this is their reply:—

"The Liliputian Dahlias are only so called by the original raiser from the relative size of the flowers, and not from their diminutive growth. As yet there are not varieties to constitute a section of the Tom Thumb stature (we wish there were, and

we fancy they are already spoken for). Up to the present time there is only about one in a score of the new introductions that is dwarf enough to be classed with the usual bedding varieties; consequently you can only make up your outer row with the lowest of the well-known bedding kinds, such as Prince Arthur, brilliant crimson; Beauty de Massifs, scarlet; and Zehnda, purple, &c.?"

WORK FOR THE WEEK.

KITCHEN GARDEN.

CLEAR off all decaying litter, and stir the surface of the soil on dry days among growing crops, as Cabbage, Spinach, &c.; also get vacant ground manured and ridged up as quickly as possible that it may be exposed to the influence of the winter. *Asparagus*, where this delicious vegetable is required through the winter, a bed should now be made for forcing it; half-spent dung mixed with a small portion of fresh, and some beech and oak leaves are better for this purpose than all new, as it maintains a steady heat for a greater length of time. Make the bed 4 feet high, and place on the frame immediately; when the heat is up, and becomes regular, level the bed, and lay on it a coating of leaf mould or any light soil 3 inches or 4 inches thick, then place the roots as thickly as possible over the bed, and cover with 3 inches of the same soil, afterwards give a good watering, and close the frame until the heat rises, when air must be given according to the state of the bed and the weather; 55° to 60° will be quite sufficient at any time. *Celery*, it is necessary to take advantage of every favourable opportunity to earth up all that requires it; rather let it remain as it is than attempt to do so while wet, as it will afterwards rot in a very short time. *Cauliflowers*, those under hand-lights and in frames to have the surface soil occasionally stirred about them, and abundance of air to be given at all opportunities. *Herb-beds*, if they are not yet cleaned and done up for the winter they should be attended to without delay; a slight coat of very rotten dung should be laid on them for the double purpose of protecting the roots from severe frost and to enrich the soil. *Lettuce*, the Cabbage varieties planted in frames, intended for winter use, will not require much air if the soil is light and dry; should they require a little water give it to each plant from a watering-pot without a rose. Never expose the plants to heavy rains. *Sea-kale*, a little leaf mould, tan, or cinder ashes to be laid over the crowns of the plants; pots may then be set over a portion of the plantation, and be covered with leaves as they are collected; if required for use in a short time stable-dung should be used. *Spinach*, when gathering the leaves the beds should be trodden upon as little as possible, as their growth is retarded by having the soil consolidated about the roots.

FLOWER GARDEN.

If the beds are now filled with the spring-flowering plants lately recommended, a regular clearing up of grass and gravel walks should take place, in order that the whole may have a neat appearance through the winter. If the walks are much out of order a surfacing of fresh gravel should be spread over the principal ones within sight of the windows, to give a degree of freshness to the scene. Complete all planting as soon as possible, and further by all available means the progress of alterations, particularly the removal of objectionable trees, which, if cut down now, may be got out in frosty mornings without much damage to the turf and walks. Take up and store *Marvel* of Peru, *Dalhia*, *Salvia splendens*, if not already done, and finish planting bulbs and Anemones. *Gladioli* to be taken up when the foliage has begun to decay, and planted in the spring. Most of the sorts like sandy peat, but they will succeed very well in any light garden soil. Now is a fine time for taking up and laying down Box edgings, and also for laying down turf; if the ground is newly made, see that it is rendered perfectly solid before laying down the turf, so that there may be no giving way afterwards. When laid down to be well beaten all over with the turf-beater to close all the edges of the turf, and to level down all irregularities.

FRUIT GARDEN.

The planting of young fruit trees and transplanting or raising those of larger growth to be vigorously prosecuted; the season is very favourable, and the earlier these operations are performed the greater will be the chance of success. Figs should be protected: a good plan is to loosen them entirely from the wall, to

tie the branches close together, and when severe weather sets in to wind tick haybands around them from bottom to top.

GREENHOUSE AND CONSERVATORY.

Creeper to be closely tied that they may interfere as little as possible with the admission of light to the interior. Let pot specimens in bloom be frequently re-arranged so as to make the most of these; for the finest specimens become too familiar to be interesting when allowed to remain too long in one place. Double Roman *Narcissus*, *Crocus*, Neapolitan *Violets*, *Mignonne*, and *Cyclamen* bloom early without much forcing, and answer well when placed on shelves at the back of the greenhouse to catch every ray of light, and to insure them from damp. As this is rather a leisure time in this department, the naming of plants should command attention. It is an additional feature of interest to see a collection of plants properly labelled with the names well written and properly spelt.

FORCING-PIT.

The stock of plants to bloom at Christmas, consisting partly of stove plants grown for the purpose and partly of forced shrubs and bulbs, should now receive some attention, particularly the latter, which should be undergoing a slight amount of forcing to get them into bloom by that time.

PITS AND FRAMES.

In fine weather, when the lights are off, look carefully over all the free-growing plants, and pinch out the tops of the shoots to keep them dwarf and bushy; also remove dead leaves. Give air freely night and day while the weather is mild, keeping the plants moderately dry. *Carnations* and *Picotees* in frames will require some attention, giving them a free circulation of air during the winter months, and water as they need it. *Auriculas* and *Polyanthuses* will require but little water; air and exposure are indispensable to these hardy alpine plants. Any premature blooms that appear to be removed. The cuttings put in late to be sored, and all that are rooted to be removed to another pit or frame where they may be gradually exposed to more air, and the others not thoroughly rooted to be replanted and kept close until they become rooted.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

PLENTY of rains at last to raise the springs and fill the tanks to the relief of everybody in this quarter, as cottagers were using water fit to bring on gouts and diseases of all kinds, and some farmers had to borrow and beg loads from their more fortunate neighbours. We managed to get most things secured out of doors, as the suddenness of the frost, and the suddenness of its going, and the great fall in the barometer, led us to expect heavy rains. In addition to what was stated last week, as to housing, &c., we raised all our early *Cabbages*, those intended for the first crop in spring, but which have got too vigorous to please us, just inserting a five-tined steel fork under them deep enough, and raising it high enough to enable us to feel the tug of the roots snapping, and then treading the earth about them again, and earthing well up against the stems. We had this done in time before the lashing rains of the 12th and 13th. During the sun of the 11th they flagged considerably, but that was what we expected and wanted. The check to growth by making the plants less stored with sap, will give them the chance of passing a sharp winter uninjured. Pricked out also lots of young *Lettuces* and *Cauliflowers* where protection of any old glass could be given to them, and whilst wet was excluded, gave plenty of air to all such things night and day. Spawned a fresh *Mushroom-bed*, and as the material was damper than we like it, wrapped each piece of spawn in a handful of dry short litter before inserting it.

UNDER GLASS.

Had all *Strawberries* and fruit trees in pots secured from wet, and in most cases covered the pots with litter or leaves to keep out severe frost, and as the weather was unfit for doing much out of doors, finished sowing pack *Geraniums*, taking up *Scarlets*, &c., that had been struck thickly in cold beds under spare sashes, and packed them thickly in shallow boxes, so as to be moved anywhere. Pruned and cleaned *Peach-house*, and filled it just now to overflowing with plants, as we shall not force early. Made these boxes, washed pots, using heated water and a comfortable shed. Washed plants that had any sign of filth on them. Potted *Cinerarias* for succession, and put them on boards in a

cold earth-pit protected with sashes. Made tallies, cut stakes, cut shreds, and got all house work forward, that on the first dry fine day all the strength may be devoted to cleaning the lawns, beds, and walks. A good sharp frost, by bringing down all the deciduous leaves, would lessen our labour in this direction. Seakale and Rhubarb have been placed in Mushroom-house.—R. F.

TRADE LISTS RECEIVED.

A Select Catalogue of Orchids, Stove, Greenhouse, and other Plants, Trees, Shrubs, &c., by B. S. Williams, Holfordway. This catalogue is particularly rich in Orchids, Exotic and British Ferns, and Stove and Greenhouse Plants. It is not often nowadays that we find so good a list of Herbaceous and Alpine Plants as Mr. Williams here enumerates, to all of which prices are affixed. It is a good and useful catalogue.

Nursery List of William Poutey, Huddersfield, 1861-2, contains the usual stock of a country nursery.

Descriptive List of Gladioli, Pansies, and Hollyhocks, by Stuart & Mein, Kelso.—To those who are interested in florists' flowers, and particularly Hollyhocks, Pansies, and Gladioli, this list will be acceptable, as it contains all the best of the novelties.

TO CORRESPONDENTS.

* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

ARTICULAS (H. M.).—Write to the nurseryman you name, and he will send you a priced catalogue. We cannot undertake to negotiate with amateurs.

HYACINTHS FOR EXHIBITION IN APRIL—CUCUMBERS (A. B.).—Your best plan with the Hyacinths will be to pot them at once; but to keep them covered up in a cool place out of doors until towards the end of March. We do not think any thing is gained by keeping the bulbs unpot, unless you could keep the roots from growing by having them in an ice-house, suspended in a basket from the roof; and thus kept you might defer potting to the end of February. Cuthill's Black Spine is a very good variety of Cucumber; so is LYN'S Conqueror of the West. For white-spined, Manchester Prize and Telegraph are good long sorts; but in exhibitions good judges will pass by mere size for symmetry and freshness.

BUYERS OF CUT FLOWERS (E. B.).—The cut-flower salesman in Covent Garden Market were alluded to by us, and their names are various. All we recollect of them now, are Mrs. Johnson and Mr. Buck.

ROOT-PRUNING (A Constant Reader).—We knew of no separate work upon this subject. Certainly the first President of the Royal Horticultural Society never published one.

VARIOUS (J. de J.).—The paper you enclosed will do very well for drying specimens of Ferns. Any thick blotting-paper—that is, unsized paper, will answer. The best book on Ferns (Foreign and British) is Hooker's "Icones Filicum." The "Florist," commencing next year, will contain illustrations of foreign flowers, popular hardy and greenhouse plants, Ferns and fruits, but not of stove plants.

DIOSCOREA BATATA (Solanium).—You may either take up the tubers and bury them in coal ashes, or you may leave them in the ground until required. They are quite hardy. Our correspondent would be glad to know of any mode of cooking them besides boiling.

GARDEN PLAN (Vinetta).—Your gardens are very well planted indeed, and your plans are so novel that we shall, before long, engrave and publish them. In plan No. 2, it will be seen the large beds are linked together in the chain manner, as other kinds of beds are in the chain patterns at the Crystal Palace, and a very effective plan it is. All the links are planted with the Variegated Balm; but *Cerastium tomentosum* is the large circle in the angle formed by the position of the two gardens comes in exceedingly well as an episode between the two systems of beds, and these two being not seen at one view, owing to the shrubs, is a great addition to the interest of the place.

STREPTOCARIS BIFLORA (C. P. M.).—*Streptocarpus biflora*, or polyantha, is a soft-wooded stove plant that flowers freely enough during the summer, if the heat for it during the winter has not been under 55° and 60° would not be too much for it during the rest period; but if it could have a cover of a Cucumber-frame from the end of February to the latter part of May, and a dry house in winter, from 50° to 55° ought to keep it safe.

GERANIUM WINTERING IN CELLAR (E. S.).—Pick off the young shoots and leaves as fast as they appear.

CYANOPHYLLUM MAGNIFICUM, and STEPHANOTIS FLORIBUNDA (B. B.).—The *Cyanophyllum* looks best when not too large, and with large leaves over the pot. To secure this you must nip off the terminal bud, or even prune the shoot well back. Fresh shoots will then break out, and give fresh, fine foliage. The *Steph. notis* will not stand if long below 50°. If never below 45° for any length of time, and generally never 50°, it will do.

HEATING A VERY SMALL PROPAGATING-HOUSE (A New Subscriber).—A small iron stove and chimney-pipe in the centre of the house as you propose is most advisable for so small a structure. The Scarlet Runner seed which you sowed had been crossed with pollen from the Dutch case-knife. The mere colour of the seed varying is no merit. The only characteristics rendering a variety worthy of propagation are superiority of produce either in quantity or quality, or in both.

PATENT IN-DOOR PLANT CASES (A. B.).—They are as effective as any other heated plant case for striking cuttings. You will see more about them several weeks. Write to the makers for information about price. You may buy choice *Minimus* seed of any of the large seedsmen who advertise in our columns.

GAS STOVE IN A GREENHOUSE (H. Lawson).—With an efficient chimney-pipe to carry off the fumes arising from the burning gas, it is a very clearly and easily managed, safe, and efficient mode of warming a greenhouse. We had one in use for several years.

BOOK ON FLOWER GARDENS (R. K.).—Messrs. Major's book on this subject is priced half-a-guinea.

NAMES OF FRUITS (G. W.).—Never pick fruit in moss; it completely destroys the flavour. No. 1, unknown, and a worse than worthless variety—it does not deserve a name; 2, *Catalpa*; 3, a beautiful specimen of *Cook's Eggplant*; 4, *Neeson's Codlin*;—(*Cold Harbour*);—No. 1, *Dumelow's Seedling*; No. 2, *Yorkshire Greening*.

INK FOR ZINC LABELS (Junior).—Scrub the labels bright with sand-paper, and write on them immediately, using a quill pen, with the following mixture:—one drachm powdered verdigris (acetate of copper); one drachm of powdered sal ammoniac (muriate of ammonia); half a drachm of lamp black; ten drachms of water. Mix these in a two-ounce phial, and shake every time you use it. It is ready for use as soon as the verdigris and sal ammoniac are dissolved.

NAMES OF PLANTS (F.).—1, *Nephradium molle*; 2, *Woodwardia (alias Doodia) crudiata*. Fairly.—It is impossible to determine sprigs of *Cupressus*, *Juniperus*, and similar Conifers. The fruit is that of some *Fagus*-genus; but we cannot name from the fruit alone. (*P. M. K.*)—The fruit is a *Physalis*, and probably *P. edulis*, the Cape Gooseberry, which, as its name implies, is edible; but you have not sent leaves and flowers in a state for exact determination. It may be cultivated very much in the same way as the Tomato. (*J. N. Gibbs*).—*Portulaca Thellusonii* (*H. Green*).—It is *Selaginella cuspidata*. (*A Dorsetshire Subscriber*).—Both specimens sterile, and therefore not readily determinable. No. 1, appears to be *Cystopteris fragilis*, var. *dentata*; 2, *Lastræa dilatata*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

WHO MAY WIN AT THE BIRMINGHAM AND CRYSTAL PALACE SHOWS.

(Continued from page 137.)

We recently had a book put into our hands professing to teach the art of insuring longevity, guaranteeing, if its rules were followed, a green old age at fourscore. The author died at thirty. The writer of a treatise which placed a fortune within every man's reach, and which rendered poverty an impossibility, died in Worcester workhouse; and the inventor of the "antifall-pilus," which prevented the hair from falling or becoming grey, was obliged to take a wig at twenty-nine, not having a hair upon his head. We who have kept poultry without taking a prize all our lives, will continue our last week's paper on the things that must be followed and avoided to insure success.

We left off at **PENCILED HAMBERGHS**, we now take their **SPANGLED** brethren. The Silvers must have spotted breasts, they must also have clear tails—that is, white tails with a distinct spot or moon at the tip of each feather; the hackles of the hens must be clouded, the wings barred, and if laced, so much the better. The combs must be firm on the head, quite straight, full of points, well piked behind, the pike inclining upwards. The body must be spangled all over. The same points apply to the cocks in almost every particular, but the barring and lacing of the wings are more desirable in them than in the hens.

In addition to these points, the Golden must have a buff tinge at the root of the feathers. The clear tails are not required here as in the Silver.

Loose combs are to be avoided, and indistinct markings. Each feather should have its clear spot, crangle, or moon, and all must have blue legs. Large unsightly combs are to be avoided in the cocks. We mean those that hang over the nostrils and partly conceal the eyes.

BRAHMA FOOTRAS may be either pencilled or light. The hena of the former should be grey all over; the latter should be white except stripes on the hackle, the flights, and the tail. The light cock should be coloured like the hens. The dark one should have black or nearly black breast, light hackle and saddle,

dark thighs. All must have feathered legs. They may be either pen or single-combed. They must be large.

SEBRIGHT BANTAMS cannot be too small, but although desirable, diminutive size cannot counter-balance defects. Choose, therefore, your birds as free as possible from hackle and saddle, with clear tails, and accurately laced feathers, strutting carriage and drooping wings, firm, full-pointed, and piked combs, straight on the head, and the pike inclining upwards. Having secured these essentials, then look for small size, which is a great element in success.

GAME BANTAMS are in many respects opposite to the Sebrights. The wings of the Game instead of drooping, must be carried well up to the body like the Game fowl. The tail must be flowing instead of round like a hen's, not carried squirrel-like over the back. The head must be fine and well set on, and the carriage bold, but not strutting and shaking. The combs of the hens should be straight.

BLACK AND WHITE BANTAMS should be small, close-feathered, and very smart. In both the cocks should have long and full tails. The Black should have white ear-lobes. Rose combs are preferred, but single ones are not disqualifications.

GEES must be heavy. **AYLESBURY DUCKS** must be heavy, and their bills must be pale. **ROVEN DUCKS** must, both duck and drake, resemble Wild Ducks absolutely in colour of plumage and bills. The larger they are the better; but no weight can compensate for faulty plumage, or green or leaden-coloured bills in the ducks. The **BLACK OR BROWN AKEAN DUCKS** should be as small as possible, close round bodies like a Wild Duck, with perfectly black plumage, brilliant with green metallic lustre. **CALL DUCKS** should be very small, with round heads and short bills.

We will conclude with a few general rules for young exhibitors—indeed, this and the preceding paper are intended only for them. We have no pretensions to teach many of our old prizetakers.

Fowls to be successful must be sent in light condition; but even in those classes where weight is an essential, mere fat will not do—large framework is necessary. Judges are not guided by mere weight, but the size of the fowl is ascertained and tested by measurement. Excessive fat, so far from being desirable, is a great disadvantage. Fowls suffering from it are necessarily dull and sleepy, they get into the corner of a cage, whence they will hardly allow themselves to be moved, and are spiritless and unattractive. The greatest amount of weight must be attained that is consistent with exercise and hard condition. Beauty of plumage is a great help to success, and this cannot exist with much fat, as its tendency is to loosen the feathers and make them hollow. Fowls should be sent to a show with clean plumage, and those that should be white, and are not white, should be washed to make them so. Soap and water may be easily and safely used with a flannel; and if the birds are afterwards put in a basket with some soft straw, and placed before a good fire, they soon become dry. All fowls should also be sent to a show with clean legs. Even where the birds shown do not belong to a breed of which feather is the principal merit, it is desirable to choose those that match as nearly as possible; and in every breed it must be recollected that positive similarity of comb and colour of legs are imperatively necessary to constitute a competing pen in any class. We have used the word "must" rather freely in some instances; we think we might substitute the word "ought." It is easier to describe perfection than to produce it, and lest any should be discouraged we tell them that even among the prize birds of Bingley Hall there are very few perfect pens.

We advise sending fowls away early to a show. They get more care in unpacking, and they look better before the Judges, from having had more time to recover the effects of packing and the journey. It is, besides, due to the members of any Committee who undertake the task of unpacking. There is no reason why they should be kept at their unpleasant work all night. It is also far better where they have a long distance before them, that fowls should travel at night. Those who manage to a nicety are sometimes too late, and at others they arrive after the Judges have commenced their work. One is almost as bad as the other. With regard to the food they should have before they start, it should be of a light character. They have no opportunity in their baskets of finding stones to assist digestion, and for that reason we object to whole corn. We believe sopped bread to be the best thing they can have, and in very severe weather it is a wise precaution to give them a part of their meal steeped in strong beer.

All baskets should be round to prevent any feathers from being broken. There is no angle in such a one for a bird to get into to escape; from beating, or to crouch to roost. If it is in motion, the tail follows round, and the feathers are not injured. The basket should be covered with double canvass. It should be large enough to allow all the birds to sit down, and high enough to allow the cock to stand upright without injury to comb or top-knot.

"WHO BOUGHT MY PEN OF FOWLS?"

ALLOW me to thank you for your reply to my inquiry as to the power of insisting upon being furnished with the name of the purchaser of my pen of poultry at the late Crystal Palace Exhibition, by Mr. Houghton, the Secretary; and as you have expressed so strong an opinion against the propriety of my doing so, I shall not further move in this matter, though I am still of opinion that in every case where it is required, the Secretary should be authorised to give the information to the seller of the poultry, and that altogether for the benefit of the breeder, and not from any ridiculous curiosity or vanity.

May I further trouble you to allow me space in your next Number to reply to an observation or two of your correspondent "A YOUNG COCHIN COCK," with whom I should be glad to be acquainted, that I might by a friendly note explain the circumstance alluded to by him, instead of troubling you and your readers with our little differences? It is true I entered a pen of birds at Worcester, one of which I bought at the Crystal Palace. In my case, however, I made no secret of it, but openly mentioned the fact to all I had the pleasure of speaking to on the subject; and at that Show it was not necessary to give the name of the breeder; and, therefore, none was given. It will give me much pleasure to meet the present owner of the poultry bred by me at Birmingham, and trust when I do so it may be to congratulate him on the further success he anticipates, assuring him that though I shall do my utmost to beat him, my next greatest satisfaction, should I fail, will be to find that I have contributed to the success of a mutual lover and patron of this beautiful breed of poultry.

I entirely disclaim all intentions of conveying, by my last note, any idea of fraud to the party alluded to; my sole wish was, as therein named, to try to stop the practice of withholding, what I thought, fair information to the breeders of poultry at future shows; and though in this instance I am for the moment apparently outvoted, I feel sure that breeders, as a class, will on reflection agree with me; and ere long for their own satisfaction assist me in placing this amongst the rules of all our leading exhibitions.—EDGAR MUSGROVE.

[We think that such a rule as Mr. Musgrove wishes for never will be added to the rules of any society desiring to be permanent. Some purchasers do not like to have known how much they gave for a pen; and others do not wish to have revealed what strains they introduce to improve their breed of fowls. Any one wishing to avoid any particular strain can easily avoid it by asking a vendor whether his birds on sale are of that strain.—EDS.]

SHEFFIELD AND HALLAMSHIRE PIGEON SHOW.

THE third annual Sheffield and Hallamshire Pigeon Show, for birds hatched in 1861, was held at the house of Mr. Mellish, Walkley, on Monday, the 3rd inst., when four beautiful silver-plated cups and other prizes were awarded as follows:—

CLASS 1.—CARRIERS.—First (the Society's cup, value two guineas), Mr. Colley. Second (a pair of beef-carvers, given by Mr. Milner), Mr. Colley.

CLASS 2.—First (the Society's cup, value two guineas), Mr. J. Smith. Second (a beautiful case of ladies' scissors, given by Mr. Colley), was awarded to Mr. Tysack. Third (a handsome pair ivory carvers, given by Mr. E. Brown), was won by Mr. H. Brown, Walkley.

VARIETY CLASS.—First (a silver cup, given by Mr. Mellish), Mr. W. Taylor, with a very fine Red Jacobin. Second (a silver cup, given by Mr. Deakin), Mr. J. Smith, with a splendid White Fantail. Third (a highly-polished back-saw, given by Mr. Tysack), Mr. H. Brown, Walkley, with also a fine White Fantail.

There were also some old birds shown by the members of the Society, among which was noticed a most splendid Carrier cock belonging to Mr. Colley, for which that gentleman has refused £20. Also, some beautiful Pouters, shown by Messrs. H. Brown, E. Brown, T. Sorby, W. Taylor, J. Smith, and others.

There was a handsome White Powder cock exhibited by one of the members, which was greatly admired by the visitors, bred by W. Tegetmeier, Esq., London.—E. B.

MR. TATE AGAIN.

In a late Number of your Journal Mr. Tate advertised "a pen of Duckwing Game fowl, winners of nine prizes, and a Black Red cock, second in the Birmingham sweepstakes, for sale or exchange." I made application for them, citing "a pen of Duckwing Bantams, a pen of Black Reds, and two ordinary Spanish pullets;" at the same time telling him, did the birds not answer the description I gave of them, he had merely to return them and it was no bargain. After a delay of some three or four days he writes, requesting me to send my birds and he would return me the Game fowl he had advertised. In the meantime I sold the Duckwing Bantams, but in their place sent him extra Black Reds, stating how and why I had done so, and, if he did not approve, the lot was to be immediately returned. This he did not do, but writes describing the lot of birds sent as "scrubby," not worth £1. Of course I remonstrated, requesting £2, the Game fowl, or my birds to be immediately returned. After continued remonstrance and threats of exposure, the grand finale is that he writes to say he will not return my birds, or will he pay for them, or send me the Game fowl promised in exchange; his apology for such conduct being that I had sold the Duckwing Bantams, and he should stick to his determination until I sent him a pen, as he considers himself an ill-used individual.

I have placed the matter in the hands of my solicitor; and I need not say I will do my best to obtain something like compensation out of Mr. Tate, be he a man of straw or not.

I trust you will give this letter publicity, as a caution to those who answer Mr. Tate's advertisements for the future. This is not the first time I find Mr. Tate has distinguished himself in your Journal.—VATASOR SANDFORD, Hon. Sec., *Pignorth Poultry Show*.

[Any one will, referring to Nos. 626 and 627 of our first series, will see how Mr. Tate conducted himself in transactions with Mrs. Cross and Mr. Baxter. We hope that Mr. Sandford will not allow trouble or expense to swerve him from the course he has adopted.—EDS.]

THE BIRMINGHAM CATTLE AND POULTRY SHOW.

We have pleasure in announcing that the thirteenth of those annual exhibitions which have rendered Bingley Hall so famous will be in all respects equal to any which have preceded it, and probably, in some departments, of unusual interest. The entries are now closed, and fully warrant these favourable anticipations. The names of many of the first supporters of the Birmingham meeting will be found in the catalogue of this year, with the addition of others who have for the first time become members, and whose co-operation is valuable, especially as showing that the influence of the Society is still extending.

	1858.	1859.	1860.	1861.
Poultry.....	1,337	1,342	1,134	1,396
Pigeons.....	222	214	168	221

The entries of poultry and Pigeons, it will be noticed, exceed those of last year by 315, so that the changes to which we have previously referred have proved satisfactory to exhibitors generally. The Poultry Committee have had all the pens altered to meet these changes, and have been enabled to give some additional space in the walks between each division; the whole of the poultry and Pigeons will also be now for the first time located in the original poultry bay, and with increased facilities for examination. These alterations will leave additional room for the exhibition of articles of an agricultural character, and this year there will be a few implements shown.—*Hidland Counties Herald*.

SMITHFIELD CLUB SHOW.—The annual Cattle Show of the Smithfield Club will once again be held in the west end of London. It is now twenty-two years since it was moved from Goswell Street to the Baker Street Bazaar, during which period it has continuously improved. The Show this year exceeds in

entries any of the preceding, and the lists comprise the names not only of the well-known exhibitors of the best prize specimens in Devons, Herefords, Shorthorns, South Downs, &c., but also those of His Royal Highness the Prince Consort, His Royal Highness the Prince of Wales, and many noblemen who take a lead in agriculture. The days appointed for the admission of the public are the 10th, 11th, 12th, and 13th December, and it is confidently expected that the Show this year (the last at the Baker Street Bazaar) will fully sustain its national reputation.

OIL PAINT ON FOWLS' FEATHERS.

HAVING had the misfortune to have some of my fowls covered with oil paint, from their getting too close to some newly-painted palings, I think I should be wrong in not letting you know for the benefit of your readers, who may have the like misfortune happen to them, that "Bonzine Collas" (obtainable at chemists) entirely removed it, even after some days, and no damage has been done to the plumage.—H.

KEEPING POULTRY ON A LARGE SCALE.

IN ANSWER to "INTENDING FARMER," we will first observe that the Land which will suit best for agricultural purposes will not be that we should select for poultry. Poor, light, sandy soil is that which is required. Chickens thrive better on that than on any other. If your intention be to sell eggs only, then we advise you to keep either Cochins or Brahmas. They are the best layers; but there is one thing you must bear in mind—only young fowls lay in the winter. No artificial warmth will make old hens lay in cold weather, nor will any of any age lay during the moulting season. We need not tell you that to make it profitable you must produce eggs when they are scarce. Really new-laid eggs are now making threepence each in London. The cost of fowls kept in laying condition, and taking the average of the year round, is from three halfpence to twopence per week—say 8s. 6d. per year. This is admitting that everything they require has to be bought; but if you keep them in a farm-yard, where food is to be picked up, the cost will be thereby diminished. Nevertheless, in calculating as you wish to do, it would hardly be safe to reckon on less than this, because filling fowls' bellies with Indian meal, rice, potatoes, and such like, is not feeding for eggs. We are not advocates for forcing by unnatural food, because it is a small temporary gain at a certain loss. You get some eggs out of season, and the hen is spoiled by disease; but we advise to counteract inclement and unfavourable weather by extra food. The warmth that is beneficial to poultry should be the produce of better food than common hot stores or hot-water pipes.

By proper painstaking, the laying of fowls may be calculated with almost the same certainty as the parturition of animals. Brahma pullets hatched in April, and Cochins in May, are sure, if they are in good condition, to lay in November. These will pay, because a few eggs in that and the two following months will pay twelve months' expense of keep; consequently those they lay afterwards and the chickens they rear will be profit. No fowls lay nine months out of the year. We cannot tell you how many acres would be necessary to enable you to keep 1000 fowls, unless we know whether they are to be the first consideration, or whether they are only to be auxiliaries. If the former, we advise you to take a place near a common, where rent is very cheap, and where you can have an extensive gratuitous run; also where you can have gravel almost for the digging, and where you can cut sods of grass you will require for such birds as are in pens. If the latter, you must greatly diminish your intended number. When you have your place, we advise you to begin with not more than from £0 to 100 pullets of the breeds we have mentioned, and be sure they are May chickens. You will not be particular as to colour or to strain, as they are only wanted for layers; and an advertisement will bring them at from three to four shillings each in July. It is not necessary to go to any expense about houses. Any out-house will do, provided it has an earthen floor, neither brick, boards, nor stones. If you are near a station, you need not care for being near London. The difference in rent between near London and some miles lower down will doubly pay railway carriage. You will, of course, understand that, after the first year, you will breed your own fowls, and every year you will clear off your old ones, except a few for mothers. We have

no doubt eggs may be made to pay. Vast numbers come from Scotland, and the trade thence is interesting. As soon as it is known your eggs can be depended upon, you will have more than a ready sale—they will be sought for.

We believe much of the extract you enclose is correct.* The amount of eggs and poultry sent to England and set at £240,000 is very much understated, while the expected increase in France is £7,315,200 to £34,425,600, or nearly 500 per cent, is ridiculous.

EXHIBITION OF CANARIES AND OTHER CAGE BIRDS AT DERBY.

On the 2nd inst., the members of the Derby Bird Society held their fourth public Exhibition of cage birds in the Athenæum Room. Although the day throughout was very cold and wintery, the Show was in every respect a far more successful one than any heretofore held in Derby. With the kind assistance the Society had received the members have been able to extend their operations, and look to the future for still greater success. The various breeds of birds exhibited were first-class, some in particular being very choice, and bearing evidence of considerable care having been bestowed in bringing them out so well. The Belgian birds were good, and much curiosity was caused from their peculiar form. The Norwich exceeded past shows, and the Lizards, Cinnamons, Mules, and other kinds were well represented. The number of birds shown exceeded last year, and some well-bred Canaries and Doves were exhibited by Mrs. W. T. Cox, of Spondon. Parrots, Goldfinches, Starlings (one of which pined "Charley o'er the water" very correctly) were represented by some choice specimens.

The Judges were Mr. Mason, Nottingham, and Mr. Matthews, Radford. The following are the awards:—

BIRDS HATCHED IN 1881.

- Clear Yellow Belgian.—First, T. Carrington. Second, S. Bunting Third, J. Price.
- Clear Buff Belgian.—First, S. Bunting. Second, T. Carrington. Third, G. Barnesby.
- Buff Marked Belgian.—First, S. Bunting. Second, J. Price
- Variiegated Yellow Belgian.—First, T. Carrington. Second, R. Smith. Third, S. Bunting. Fourth, G. Barnesby.
- Variiegated Buff Belgian.—First, J. Price. Second, J. Brodie. Third, T. Carrington. Fourth, G. Barnesby.
- London Fairy.—Prize, G. Barnesby.
- Clear Yellow Norwich.—First, H. Beeston. Second, E. Orme. Third, R. Smith. Fourth, J. Pimm. Fifth, G. Barnesby. Sixth, J. Boden.
- Clear Buff Norwich.—First, E. Orme. Second, G. Barnesby. Third, E. Smith.
- Golden-spangled Lizards.—First, G. Barnesby. Second, H. Beeston. Third, J. Price.
- Silver-spangled Lizards.—First, L. Duxton. Second, E. Orme. Third, T. Carrington. Fourth, J. Price.
- Jouque and/or Cross-bred.—Prize, J. McConnell. Second, G. Barnesby.
- Meady Spot or Cross-bred.—Prize, J. Bodie.
- Cinnamon (Mottled).—Prize, G. Barnesby.
- Buff Crested.—Prize, R. Bond.
- Jouque Goldfinch Mule.—Prize, G. Barnesby.
- Meady Goldfinch Mule.—First, E. Orme. Second, T. Carrington.

BIRDS OF ALL AGES.

- Clear Yellow Belgian.—First, E. Orme. Second, S. Bunting. Third, R. Smith. Fourth, R. Stanland. Fifth, T. Crocker. Sixth, J. Price.
- Clear Buff Belgian.—First, J. Price. Second and Third, S. Bunting.
- Variiegated Yellow Belgian.—First, J. Fisher. Second, R. Smith.
- Variiegated Buff Belgian.—First, E. Orme. Second, T. Keys. Third and Fourth, J. Price.
- Clear Yellow Norwich.—First, J. Pimm. Second, E. Orme. Third, G. Barnesby. Fourth, J. Price.
- Clear Buff Norwich.—First, G. Barnesby. Second, E. Orme.
- Yellow Marked Norwich.—Prize, J. Bodie.
- Yellow-spangled Lizards.—Prize, S. Bunting.
- Silver-spangled Lizards.—Prize, S. Bunting.
- Meady Goldfinch Mule.—First and Second, E. Coke. Third, E. Orme. Fourth, E. Coke. Fifth, S. Keys.
- Lined Mule.—Prize, J. Hall.

—G. J. BARNESBY, 132, *Abley Street, Derby.*

SPARROWS MISTAKING THE SEASON.

INSTRUMENT FOR TEACHING BIRDS.

A QUANTITY of sparrows have been observed busily collecting straws, moss, and feathers and carrying them away, during last month, and even this morning (November 8th). Is it possible that they are building now? If so, it must be a singular proof of the mildness of the season.

Can any reader of the Journal give the writer any information as to self-playing instruments for teaching tunes to birds? She has a s-metric, but its tunes are too complicated and not sufficiently flute-like. She heard a report of some German contrivance which was very suitable, but does not know its name, or where it can be met with.—E. A. M.

[If the sparrows are building, it is an illustration of Cowper's verses on a similar transaction, and we have no doubt that there will be a similar climax. Snow came, and then

"Into their nests they padded,
Themselves were chilled, their eggs were added:
They pined without the least regret,
Except that they had ever met."]

THE CANARY AND THE BRITISH FINCHES

(Continued from page 38.)

THE CAGE.

THERE is an old saying, "Get a cage before you buy a bird." This, like many other pieces of good advice, is often omitted, and the possessor of a bird is at first frequently obliged to beg or borrow some old or dilapidated prison for his newly-acquired favourite until some convenient opportunity offers of procuring a new one. The cage, when bought, is sometimes only a showy gimcrack, made more to catch the eye of the purchaser than for the comfort and well-being of the future occupant, and, I believe, it sometimes happens that, owing to the hole being too small for the bird to put its head through to get its seed or water, that the poor bird dies soon after being placed in its handsome dwelling, and then the bird dealer is blamed for some supposed injury done to the individual, instead of the oversight in having the cage adapted to the bird that is to live in it; for the hole through which a Canary or Goldfinch could reach its food or water with ease, would be too small to admit the head of a Greenfinch or Bullfinch to pass.

Of course, much must be left to the taste or fancy of the individual, and a cage is none the worse for being handsome and elegantly ornamented, provided the convenience and health of the inmate are not overlooked. I will, therefore, offer a few remarks on the common faults to which cages are liable.

The hole or holes through which the bird is expected to put its head to obtain its water or food, must be sufficiently large to permit the head to pass easily, yet not so large as to allow the shoulders to be squeezed through, or on the removal of the glass, or drawer, the bird may make its escape and fly away, or fall a prey to some cat. I have also known a bird to take fright and force its way through the hole into the water-glass and be drowned. The food and water should be so placed that the bird can see it and easily procure it, and yet not throw it over, dirty it, or otherwise waste it. The floor should draw out for the facility of cleaning, and to contain the sand so essential to the well-being of all birds. The perches should be sufficiently large for the bird to sit securely and grasp them firmly with its feet, and they should not cross each other, nor be so placed that when the bird sits on one a lower one can be soiled, as this dirties their feet and often causes very troublesome sores. The upper perch, or perches, should not be near the top of the cage, as that causes the bird to acquire a habit of stooping, which spoils his appearance, and in which constrained position he cannot give full force to his melodious voice. Perhaps, however, there is one exception to this rule. I refer to the Hoopoe Belgian fancy where stooping is regarded as a beauty. In all other cases it should be avoided as much as possible. Of the wires I would say, they should not be too far apart to admit the escape of the prisoner, and brass or copper wires are to be avoided. The brass are very apt to break, and both if they get dirty produce verdigris, which is poisonous.

If the bird is to be hung out of doors in fine weather, which is generally advisable where safe, it is well to have the roof of the cage covered to keep off the too-direct rays of the sun and protect its contents from a hasty shower. If the cage is hung

FRENCH POULTRY.—The following are the statistics of French poultry:—The whole country rears 30,869,000 hens, yield her 3,713,200,000 eggs, of the value of 148,608,000 francs (£5,944,320). When to this we add the value of birds as such, the number of cocks, pullets, and capons, we find that the entire produce of poultry in France may be valued at 182,584,000 francs (£7,315,200). But while this may be regarded as the actual produce of France at the present time, an immense increase is calculated upon. By an improved system of feeding, and by increasing the amount of laying eggs by means of artificial heat, the grand total is enlarged from the amount just named to 853,600,000 francs (£34,425,600). Eggs are consumed in Paris to the amount of 3,787,243 lbs. weight annually; and in many parts of the country they constitute, along with bacon, the principal food of the inhabitants. France exports to England, in eggs and poultry, to the value of 5,000,000 francs annually (£210,000); and also largely to Russia, Spain, and Switzerland.

where it is likely to be in a draught, one side and the back as well as the top of the cage should be close, to give the bird a secure retreat, for although fresh air is conducive to health, yet many birds contract coughs, asthma, and inflammation, which affect their voice and frequently kill them, from too great or sudden a change in temperature, or being exposed to a direct draught. The door of the cage is often so placed that it is very difficult to catch or remove the bird when desirable, and it should be so made that the bath can easily be attached, as frequent bathing is conducive to the health and enjoyment of all birds.

Having now enumerated a few of the inconveniences attending cages in general, I will endeavour to sketch what I consider a plain and useful sort, one that will conduce to the health and enjoyment of the occupant; and as the well-being of the bird also adds to the pleasure of keeping it, the attainment of the one is the fulfilment of the other. The larger the cage is in accordance with the facility of removal, or the space appropriated to it, the better, as the more room and exercise the bird can take the better will be the condition of the plumage as well as its general health. I, therefore, advise, that a cage intended for a Canary or any of our British Finches should be at least 1 foot high in the clear, 9 inches wide, and 6 inches deep from back to front. The upper perch should be 6 inches from the top of the cage to give the bird room to stand erect and hold up his head boldly when he sings. I prefer the cage somewhat larger than the above, the smaller size being scarcely adapted for larger birds than Siskins, Redpolls, or Aberdevines.

UNIVERSAL CAGE.

- | | |
|---------------------------------------|----------------|
| A Sloped top to keep off sun or rain. | E Water glass. |
| B Slide bottom for sand. | F Small pan. |
| C Seed drawer. | G Door. |
| | H H Perches. |

The form I like best is that shown in the accompanying drawing, which will explain bet or than I can in words. The bird is there represented sitting on the upper perch, and he is not cramped for room. The perches do not cross. The food-drawer being outside the cage, the seed is kept clean. The slide at the bottom allows the whole of the floor to be sanded. The door in front is convenient for hanging on the bath, and the overhanging slanting roof affords the bird shade or protection from a shower. It can be made cheap in deal, painted outside and whitewashed in, the lattice being of galvanised iron wire, or it might be made in stained oak, or polished mahogany, and ornamented to any degree for taste or elegance.

This form of cage appears to be best adapted to the comfort and convenience of birds in general, and can be enlarged to suit any sort, as, for instance, a Thrush or Magpie. It may have a bow front for a Skylark, or may be made lower and longer with a single row of perches for a Titlark or Wagtail. Fanciers of the Hooped or Loved Belgians might like the roof lower, so as to keep the bird's head down; while the Scotch fancier will have it longer, with two parallel perches that the bird may leap from one to the other, to show off his whisk and wheel so characteristic a feature in their breed.

If the place where the bird is to be kept is subject to draughts or currents of air, one or both sides may be made close-boarded

so as effectually to protect the occupant, otherwise the cage cannot well be too light and airy.—D. P. BRENT.

(To be continued.)

DRONE INFLUENCE.

On the 19th of October I met with another instance in which common queens had been hybridised by my Ligurian drones. Although the distance in this case (one mile) was less than in the two former instances which have already been narrated, the circumstance was in other respects still more remarkable, only one stock having survived last winter had thrown two fine swarms, and both young queens had been impregnated by my Italian drones. What rendered the affair more amusing was the fact that the gentleman to whom they belonged appeared to share Col. Newman's predilections in favour of the old race of black bees. His own, in particular, he informed me, were brought from Cornwall, and were a peculiarly "fine sort." He really appeared not a little chagrined at my pointing out a goodly number of Ligurians in the old hive as well as in the second swarm; but seemed to obtain some little comfort in disregarding my recommendation to "take" the first swarm and preserve the young queens. I, then, drove the old stock; and the next day forwarded its hybridised queen to "A NORTH LANCASHIRE BEE-KEEPER," with a request that her adventures might be duly chronicled in THE JOURNAL OF HORTICULTURE. I am, however, quite uncertain whether she may have reached him, as neither her arrival nor that of a post-office order which preceded her has been acknowledged.

These repeated instances which have come under my observation of young queens being hybridised by Ligurian drones, at distances varying from one to two miles, and which are, probably, but a small minority of the cases which have actually occurred, prove how general and wide-spread that influence must have been. As the Ligurian species becomes more extensively disseminated, it appears probable that few apiaries will entirely escape; and it is just possible that before very long we may learn with what feelings of horror and amazement Lieut.-Col. Newman himself may have contemplated the hated orange colour, daunted before his eyes by his own bees in his own apiary.—A DEVONSHIRE BEE-KEEPER.

HOW IT FARED WITH THE PLUVIANS' SEA-ON OF 1861.

(Continued from page 120.)

Honey Harvest—Straining Honey—Beat-out Bees in Frame-hives—Ligurians.

We would have been quite honeyless, but incidentally reaped a little harvest after this fashion. There were two hives we wished to people with the swarms from a couple of stocks that thought better of it than swarm in such weather. On the 15th of August they were densely packed, crowding up front and sides close to the suffocating-point. We had heard a few days before of two stocks having been lost this way: we therefore inverted these, and beat out the entire population into the hives. Their little honey we found stored chiefly in the upper box of both, the great body of the comb being firmly attached to the moveable cross-stick in the tier of ekes below, both having been wrought on the adapter plan (described in No. 5). We therefore, severed with a thread the boxes from off the ekes; these with a few choicer pieces of end-combs, sent in to the house. The tier of ekes we found to contain, besides the little honey left, a large quantity of brood, which we were loth to sacrifice. To strengthen two second swarms we slipped a set of ekes below each, which, crowding down upon the combs, slaughtered a little band of nurses, which, faithful to their duty, would not quit their post—and took their place.

On going in we saw female fingers had been busy with the combs; these had been broken into little portions an inch or so square, while yet warm, and placed on a large hair-sieve, or search, used for the purpose; on raising which we found the wash-hand basin underneath already full. Another, subsequently barely filled was all our honey harvest.

It generally gets a second run through the sieve to catch any speck of comb that may have fallen in. What a creeping thrill of horror you must have sent through many a reader by quoting, uncondemned, the abominable Yankee receipt in No. 21. "Honey, wax, and bee-bread, well watered, put into a pot to simmer on

the fire." Dreadful! Honey connoisseurs very properly object to the most distant approach to the fire, to facilitate its running through a flannel bag even, and will not allow a steel knife to touch their comb. A fruit one might serve the end in "B. & W.'s" excellent plan.

Beginning of September found our beat-out bees, although nearly 6 lbs. in each, still in almost combless hives, although regularly fed at intervals; and, having had painful experience of how little honey can be manufactured out of 20 lbs. of sugar at the end of the season, saw we must change our tactics. The first idea was to put the two together, and feed on; then, recollecting the ekes, withdrew them, and found the brood hatched out and honey gone, so turning out a couple new hives, cut up the empty comb into squares and fitted into their frames; with a long-piped tin can (such as enginemen use for oil), introduced as much food as would supply their immediate wants. Had the combs been built, not merely jammed into the frame, we would have introduced their full supply at once, which we had found previously saves the bees the labour and waste of storing. Then, reversing the empty hives, placed the frame ones above, a warning knock or two all round, a rest to allow them to load with any surplus store, and then rub-a-dub, up they go. Never did party of emigrants, shivering on the Southern Ocean on short allowance, with starvation staring them in the face, put foot on land of plenty with greater manifestations of joy than did our poor beat-outs. It was quite a treat to see them chase each other in and out when set upon their boards; then pause to hum forth their delight with quick fanning wings: first transports over, then go in quick succession to the fields, to return shortly, tearing in three and four abreast, heavily pollen laden. Curiosity tempting us to raise the frames a few days thereafter, found all deficiencies made up, passages cut where most required, the whole combs fixed with a firmness round and round the frames that "A DEVONSHIRE BEE-KEEPER," might safely transmit one of his alpine stocks to the antipodes without fear of catastrophe. They have since had a sufficiency of food administered, and we little fear the beat-outs will not be our worst stocks next season.

In reply to your correspondent's other inquiry, as to "How it fared with our Lianians?" We can only say that "A DEVONSHIRE BEE-KEEPER" keeps us as some of our rougher sex fair ladies of a certain age—still in the world of hope, none of the goody array of twenty-four queens of stocks having come our way, otherwise it would have afforded us much pleasure to supply our southern brethren with some data as to our experience of the yellow foreigners, and their capabilities for the chilly north.—A RENTREWSHIRE BEE-KEEPER.

UNITING BEES.

I WAS more than astonished to observe, at page 98, so very able a correspondent as "A DEVONSHIRE BEE-KEEPER," instead of confirming my correction of the editorial "slip of the pen," of the 28th ult., regarding the junction of "A. W.'s" hives, endorse that error.

Surely your contributor, from his clever manipulations with queens, has attained a talismanic influence over them, second only to Wildman's, when with him they can be induced along with their subjects to follow a course so opposite to their instincts and universal practice.

In my experience of stovifying I never yet met with an instance in which the bees in such circumstances did not ascend; and I cannot suppose that a single apiarian, at all familiar with that system, will coincide with his opinion.

"A. W." may possibly kindly inform us by-and-by if the result in his case was any variation from the general rule.

I propose in an early Number approaching the vexed question as to how, if not invariably without even a slight skirmish, at all events no great pitched battle, the forces of the confederates may be best made to coalesce with the federals into a lasting union.—A RENTREWSHIRE BEE-KEEPER.

MISADVENTURE WITH A HYBRIDISED QUEEN.

AS I can quite well fancy the gratification and amusement it must afford "A DEVONSHIRE BEE-KEEPER" to learn the subsequent adventures of the little emigrants despatched from his

apiary, I will endeavour to describe at length what befell the party of the 10th October.

On Monday evening the 11th the little box reached its journey's end. On applying it to the ear all was still, so having my misgivings set it on the parlour table and undid the screws; was agreeably surprised to find not a bee dropped, on the contrary, all clustering upon the comb in fine condition, moving along so briskly that I was glad to slip a piece of glass on in lieu of the lid to prolong my examination of the nest and careful arrangements you had provided for their comfortable and safe transit. I endeavoured to get a glimpse of the queen, in this, however, I was unsuccessful, but could see distinctly the orange belts on several workers establishing their Italian paternity. I then replaced the lid with only one regret, that it was not a party of the "real Mackay's" that had so safely reached me. Before removing it from the heated room, there was one defect in your plan caught my eye, capable, I think, of improvement, and to which, at that moment, I little imagined I would afterwards have mainly to ascribe the cause of failure.

The following day (Tuesday) it rained incessantly, as only we Pluvians know how; the next, having occasion to go home, was anxious it would clear so as to afford me an opportunity of capturing the queen and putting things in a train before going. I had half a mind to transfer the hive to an out-house, and there under cover attempt the operation, although I knew it would cost me a loss of many workers. However, as luck would have it, it fared half an hour before dusk, so summoning my "Old Botherton," who, by the way, from his very long experience, evidently thinks himself vastly a-head of his master's innovations, and in the present instance thought disturbing a hive at that time in the evening, with everything dripping wet, for the senseless proceeding of introducing a queen I knew nothing of for the best-breeding young queen of my most prosperous stock, must be, after all, sheer nonsense. However, setting him in better humour by ordering his pipe a-going, caused him to introduce a few whiffs at the entrance, ran it in, undid the screws, raised the frame to the right of central slide, but no queen to be seen. How could I expect to find her at that hour, now getting dark? chimed in "Botherton," at my elbow, let it down again, raised the one to the left, and there she was, the first bee that caught my eye, scampering along, plainly observable against the white background of pure sealed food, lately introduced into this season's comb, caught her by the wings and placed her below a tumbler, then set in the frame and ran in the slides so far, laying a sheet of perforated zinc above, on which I placed the inverted unlidded box containing the "Newcomes."

With the proverbial caniness of my countrymen, thought, in case of mishap, it might be well to preserve the very large handsome monarch perambulating the tumbler; so, getting my hands on a little circular lappet box I took it to be bored numerous little holes for ventilation, and fixed a piece of empty comb in the centre, to which I transferred the queen, throwing over the top the black-crape veil that defended the physog. of "Botherton." Finding picking up bees at the entrance a slow process, I got a quill cut in the form of a tooth-pick, and into it a little honey. By inserting at the entrance, I found from the attraction of the honey I could raise half-a-dozen at a time into the box, the edge of the acft rail wiping them into it. I had by this means a goody train in a few minutes to remove along with her to the house, placed a little feeding-bottle above, and, from the pleased hum, judged they were employed carrying it into the comb.

Wednesday absent all day till late in the evening. Our people reported then that this particular hive had been in a very confused state all day; bees running in and out, and up the front: this surprised me, having their new queen above.

Thursday forenoon when all ready for the inauguration, you may judge of my disappointment on reinventing the little box, to find a number of the inmates dead, the remainder in a damp claggy condition, arising from the heat of the strong colony melting the food that had accumulated on the bottom during their journey coming down upon them. After the box was inverted, I took out the comb and spread the bees upon a board, and went over them singly several times without seeing anything of a queen.

My first surmise, could "A DEVONSHIRE BEE-KEEPER" have playfully wished us to make an involuntary experiment to establish the truthfulness of the doctrine of "Parthenogenesis?" was equally absurd with the second. Could she have been ab-

strated by the way? ending with the only feasible one that she was one of the dead bees, whose unequal proportions the fell destroyer had so shrink up as to cause her, in then clogged condition to be indistinguishable from her meener subjects.

The improvement I hinted at above would be instead of making the bottoms of your boxes fixtures, secure with four screws as in the top; any loose food could be thus removed with the bottom, and if left on the zinc without inverting, a piece of glass being substituted for the top after its removal, would thereby afford a glimpse of the junction.

The strange bees I put into a glass on the top in a heap, admitting the natives, who shortly appeared with them at the entrance quivering in their last agonies.

Thinking it high time to look after my dethroned queen, fetched the little box and drew off the rail, lifted out the comb, now stored with food, the queen pacing along it; put it to the entrance into which she slipped with as much apparent delight as her subjects at receiving her: thus ended my first attempt at introducing a queen all the way from Devonshire. Thankful it was not worse, and hopeful my next with a pure Ligurian might be more successful.—A DEVONSHIRE BEE-KEEPER.

[The moral of the foregoing story and very many similar ones is, that I find it impossible to continue the troublesome process of rearing and despatching young Ligurian queens, backed as it is by repeated failures attending their introduction to stocks of common bees. I intend offering to such of my subscribers as may not have received queens the option of taking Ligurian stocks at a reduction of one guinea from the ordinary rates, and myself guaranteeing the safe transit of the queen and the bulk of the bees in each case.—A DEVONSHIRE BEE-KEEPER.]

RABBIT-BREEDING IN FRANCE.—The *Aigle du Midi* states that a farmer named Pinel, of Ezeval, in the department of the Haute-Garonne, has lately commenced breeding Rabbits on an extensive scale for consumption, and that he expects the operation to be successful in a commercial point of view. In the space of five months from May last, he, with 60 female and 5 male Rabbits, obtained 3000 young, and he now intends to have 200 females. By allowing these latter to produce only every two months, instead of every month, as they can do, he calculates that he can procure 560 Rabbits a-month, or 6000 a-year. He has had constructed a large shed, 30 metres long by 20 metres wide, and 10 feet high, and in it are 110 compartments, of which 10 are set apart for young Rabbits separated from their dams, 13 for the adults, 12 for the males, and the rest for doe Rabbits and other purposes. Pinel makes this calculation:—Out of 270 Rabbits born every month the average number of deaths is 12, so that there remain for sale 258, which can be disposed of for 1*l.* 10*s.* each, making 283*l.* 8*s.*, or 3405*l.* 6*s.* a-year. This sum is increased to 4653*l.* 6*s.* by the sale of the manure. The expense of producing 258 Rabbits is estimated at 1372*l.*, so that a clear profit remains of 3281*l.* 6*s.* As Rabbits can be fed in great part on the refuse of the farm-house and farm-yard, it is thought that peasants might, like Pinel, breed them with advantage.

VARIETIES.

MALTESE GARDEN.—Behind one of the dwellings is a very interesting spot. This is a beautiful garden buried deep among the lofty walls and defences of the place. It is a bright little gem in a wilderness of masonry, and is almost the only real garden, in the English sense of the word, that exists in Malta. A magnificent growth of dazzling bright immense Geraniums abound here, such as would carry off the first prize in an English horticultural exhibition. Large-climbing Convolvuli and masses of *Mossabanthemum* trail about the walls and rockwork. Fine standard Roses and smaller Japan and monthly ones are interspersed among the beds, which are thickly covered with the bright blossoms of annuals. Palms, Lemons, Oranges, and Myrtles, overtop the whole. Even in England this would be a pretty garden; but it shines as a far more interesting charm of verdure and bright colour from being buried deep among the stone walls and terraces of a Maltese peninsula. (*Tillich's Malta*.)

THE LAW OF SEAWEED.—The laws of floatam and jetsam, of weeds and strays, received a curious illustration the other day at Cahireevan Quarter Sessions. The plaintiff in the case was a farmer named Daniel Fenton; the defendant was John Reilly,

apparently an agent or bailiff of no less a personage than the Marquis of Lansdowne. The case excited very considerable local interest, and the decision arrived at is of importance to all farmers dwelling on or near the sea-coast. It appears that the winds blow great quantities of floating seaweed into Ballinskelligs Bay. These floating weeds are valuable as manure, and for generations the neighbouring farmers have collected them. We gather from the trial that the Marquis of Lansdowne has endeavoured to prevent the farmers from gathering in this weed, which the wind sends floating on the waves to them. Daniel Fenton, the plaintiff, knew the law. He was quite aware that if the seaweed rested on the shore, or became embedded on the rocks, he dared not touch it. He adopted the curious expedient of backing his cart into the tide at extreme low water; there he and his assistants, proceeding up to their waists into the sea, collected the weeds as they floated, with long rakes, and placed them in his cart. His cart was full and he was preparing to drive home, when John Reilly and his assistants overturned the cart, and threw the weeds into the sea. It was nominally to recover the value of the weeds—4*s.*, that the action was brought. The real question at issue was, whether the Marquis of Lansdowne, or his agents, had power to prevent the collection of the seaweed. The Chairman of the county considered that the question was simply, whether the plaintiff had a right to take floating weed, and he ruled in the affirmative, on the ground that "the moment the water covers the place between high and low-water mark, it becomes the Queen's highway, and any weeds taken floating become the property of the captor." He concluded by giving the plaintiff a formal decree for the 4*s.* It is very probable that Lord Lansdowne knows nothing of what his steward or agents have done in this case: they were, of course, performing what they believed to be their duty to their employer; but the exercise of a private right, real or supposed, to its extreme limit, creates in the mind of the poorer classes anything but kindly feelings. The question decided at Cahireevan is by no means so trifling as it at first appears, and as it would be if confined to a single locality. The rights involved in it really extend wherever the sea wind blows, and the tide brings in to us its weeds and strays—that is, round the whole circuit of the Irish coast.—(*Irish Times*.)

RANCID LARD.—A correspondent of the *Country Gentleman* states that chloride of soda will render rancid lard perfectly sweet. He had 40 lbs. of rancid lard, and he put 3 ozs. of chloride of soda into a pailful of hot water, and then put in the lard and boiled the two together for an hour or two. When nearly cold, the lard was taken off and afterwards boiled up. "The colour was restored to an alabaster white, and the lard was as sweet as a rose."

OUR LETTER BOX.

KILLING POULTRY (A Subscriber).—The most merciful and best way is to dislocate their necks, and then run a knife through their neck, just below the ear. All sensation is taken away by the dislocation. The bleeding renders the flesh whiter.

CARRIAGE OF POULTRY TO CRISTAL PALACE (H. F. Z.).—If you write to Mr. Houghton, Secretary of Poultry Shows, Crystal Palace, Sydenham, he will write to you all the information you require.

PIGEONS (G. L.).—Your description of the pigeons is almost the same as Mr. Moore (1753) gives of the Laughers, so that they may be of that breed; but I could not give a certain opinion without hearing them coo.—R. P. BENT.

SWANS DYING IN THE WATER (G. R. Hoadsill).—A gallon of corn per diem ought to keep two Swans in good condition; yet it seems curious they should die just as their natural food, the water, should be rotting and disappearing from the water. The small number of grains of corn in each instance is also curious. You do not say if they were thin. If they were, we should be inclined to think their food has not been sufficient, and that the quantity that kept them in the summer while there was plenty of natural food did not suffice when that failed. Are you sure the Ducks cannot reach the place where the Swans' food was placed? If they died in good flesh and condition, it was from something they picked up; but it is hard to poison water-fowl.

LONDON MARKETS.—NOVEMBER 18.

POULTRY.

Throughout the year we have had to report bad trade and bad supply. It seems as though it would be a cuckoo-note to the end, for it is again our report this week.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 47.4° and 34.7° respectively. The greatest heat, 62°, occurred on the 1st in 1857; and the lowest cold, 19°, on the 30th in 1856. During the period 121 days were fine, and on 117 rain fell.

FLORISTS' FLOWERS IN THE ASCENDANT.

specifying the kinds, and how they bloom with them, as a collection of these various experiences would tend greatly to fix the value of the various kinds.

Another proof of the increased attention given to florists' flowers: and the force of opinion on such matters is to be found in the very significant fact that a contemporary, who heretofore has ignored the subject, and who wrote some very hard and ungenerous remarks on the Dahlias and Gladioli, has latterly actually given articles on the subject. And though they have been infinitely amusing to all who know anything of the subject, reminding one very much of the fable, in which a certain animal assayed the part of a lap dog to the infinite horror of its master, yet the fact is worth something, for we may be sure it would never have ventured on these had not public opinion and taste run that way: and although it may be a question whether its advocacy may not, as is usually its fate, do more harm than good, yet we accept it as a good sign. I believe that I am justified also in saying that the schedule of the Royal Horticultural Society for the coming year will be the most liberal towards florists that it has ever issued, and that each darling pet of the fancy will be honoured in its proper season.

The Royal Botanic Society, which has always taken a wide and liberal view of this subject, and has encouraged florists at its exhibitions, is going to increase the number of its small spring shows, and thus give encouragement to other supporters and friends: and the Crystal Palace Company will hardly be behindhand. It will be a busy year for exhibitors, and an interesting one for frequenters of the exhibitions. I think also that amidst other flowers the stir is equally great. One friend, who has raised the best *Verbena* of the year, Foxhunter, says that he has saved an immense quantity of seed of the finest varieties, and that he seriously contemplates taking in a portion of his farm to grow them. The season has been a favourable one for producing seed, and I doubt not from various quarters we shall have many novelties to examine and report on at the various places where such things are shown. The more the merrier. But, my friends, be careful! Consider what good things we have, and how difficult it is to beat many already enjoying the smile of public favour. You will have something to do, Mr. Millar, to beat Foxhunter; and so will you, Mr. Perry, to match some of your beautiful-eyed varieties.

Then look at the *Gladioli*. Why, there is such a rage for it, that all the "Doctors" in the world can no more stop their almost annual growth than could Mrs. Partington keep out the sea. My friend Mr. Standish is overwhelmed with demands for sorts which he cannot satisfy; and we shall see, I expect, such an exhibition of them next season as has never been witnessed before.

Then there is our dear and beloved Queen—the *Rose*. How eagerly she is sought after this season! How England and France have been hunted over to supply the demand! Some sorts are absolutely unattainable, and those that are are very much dearer than usual. Oh! what a tournament, if we have anything like a

UNMISTAKEABLE signs are manifesting themselves in various quarters that my old friends and favourites, florists' flowers, are about to raise their heads once more, and that there will be found shortly many who will not begrudge the time and trouble necessary for their proper cultivation. This is a result in which I am sure many will rejoice, and I may, therefore, with some degree of propriety, draw attention to some of the symptoms of returning life, which are apparent to me, and which lead me to the conclusion that the year 1862 will be, if the season be at all favourable, the most interesting that we florists have enjoyed for many years.

Many of the readers of THE JOURNAL OF HORTICULTURE are aware how constantly I

have harped upon the subject of a national exhibition of *Auriculas*. For the last two years I have tried my utmost to stir up growers to something of the kind, and last year my valued friend, the Rev. George Jenks, of Alford, and Mr. Turner, of Slough, contributed somewhat towards that end at one of the spring meetings of the Royal Botanic Society. Well, this month, I have received a communication from York, saying that the growers, both there and at Halifax, are very anxious to see this object carried out, and requesting co-operation. This looks hopeful, though there are many difficulties as to time and place yet to be surmounted before this is accomplished; for there have been the stumbling-blocks in the way of these national shows, and which have stripped the *Carnation* and *Picotee* Society of its national character, and made the *Tulip* one so difficult of arrangement. But withal, I cannot but hope that next year will see some advance made towards it; and, it is to be hoped, its actual accomplishment. It will gladden the hearts of all *Auricula* growers. It is an encouraging thing, too, in connection with this flower that so great a demand exists for it at present. I sent a list of some I wanted to a nurseryman, and was answered that he had only one of the sorts to sell; while another has applied to me to know if I had any surplus stock to part with; while from other growers I hear of demands made which they are unable to meet. All growers of this flower would confer a great favour on me and on the *Auricula* public if they would keep short and simple notes of their bloom,

favourable season, we shall have in her favour next year!—what challenges will be accepted!—what rivalry of charms!—what high-sounding eulogies!—what extravagance of language to describe her beauty! Ah! may I be there to see and hear.

Pansies, too—aye, turn not up your noses, my gentle heroes, Pansies are re-appearing, and see if we have not around the stands many a goodly bevy of fair dames and gallant men who will take far more interest in them than in the sporting of some new Caladium, or the fructification of some out-of-the-way Fern. I might run through the list, and show that there are many signs of returning life to us; but let this suffice. Dahlia growers, do not be afraid; do not throw away your roots. Your pets will hold their heads well up; and, in fact, to all florists, professional or amateurs, I say take heart of grace; but do let us have the benefit of your observations, and we shall then see our favourites more than ever established in the good graces of the public. *An revoir!—D., Deal.*

CALLS AT NURSERIES.

MR. SALTER, VERSAILLES NURSERY, HAMMERSMITH.

TRUE as the magnet, there is no place like home after all. You may go to the "inner quadrangle" of the soul of gardening at South Kensington, or to the crystal fountains on the heights of Sydenham, or to court, or camp, or cloister, or high festive dats, and satiate, to the full, the feelings of the hour, and yet there is a void. And so it is in botany and gardening, and in Sam Slick "natur" there is like that which, alone, could fill up the void here, and a visit to Versailles Nursery, and to Mr. John and Mr. Alfred Salter, is just like going home, you find nature there. I mean at your own fireside, and in their winter garden, which is just now in the very height of its fashionable season, full of "Good Gracious" things, and quite as full of novelties and new notions.

The first turn was to see all the new Chrysanthemums which Mr. Salter sent out for the first time last spring, beginning with Lady Hardinge, rose and blush tipped; a splendid incurved flower. Rildeman, which was very choice at the two great exhibitions. Boadicea, the nearest to Novelty in size, and the first good improvement on the size and tints of Dupont de l'Eure. Ariadne, quite changed from what it was as a seedling, a creamy buff. It is now one of the most telling flowers in a conservatory, as deep at the circumference as Wonderful, and hence shading upwards lighter and more lightly to the very centre as no wood-work could imitate. Garibaldi, a very large, flat, incurved flower, of a reddish-chestnut. Prince Consort, a fine, full, incurved, dark purple. Caractacus, a fine rose carmine, tipped blush. Penelope, a splendid rosy orange, flower closely incurved. Phobus, a golden orange, and a most valuable conservatory flower, coming in late, and keeping long in bloom. Pandora, the nearest in colour to Golden Queen of England, and described so from the exhibitions. Little Harry, a new colour, a golden amber, and a public favourite. Yellow King, a sport from its ancient majesty, and good as he. Golden Hermione, a sport from Hermione, and equal to herself. Emily, a shaded French white, or what they call delicate blush; but all blushes come of delicacy.

The next group is the tiptoe of '862. The new sorts to follow the above next spring, and really some of them are fast improvements on their respective tints and sections. General Slade, one of the very best of them; Dupont de l'Eure is good; Boadicea is better; and General Slade is best in that style, best in size, shape, and colour. Carissima, a fine creamy white flower, bushed all over with various shades of pink; a lovely thing. Duchess of Wellington, a large, rosy lilac flower, of great merit. Sparkler, a perfect model of true natural incurvity. Sparkler is in the same degree from Pio Nono that General Slade holds in respect to Dupont de l'Eure, and the two will be favourites for years to come. Miss Slade, a fine, full flower, and pale sulphur, dying pure white. Tom, a fine pure white, fully incurved. Dido, a white globular flower suffused with canopy, and will be an exhibition plant, being dwarf, free, and constant. Sylphide, delicate lilac of the first class in character. Dr. Brock, reddish-orange, fully incurved. Chorb, a magnificent flower, an amber falling into fawn tints, and suffused all over with light rose; a lady's flower to the last flower. Seraph, a fine pale primrose, dying off white. Draco, a fiery red; a dwarf free bloomer. Lord of the Isles, the next lighter shade to Boadicea, and quite as large a flower of the same race. Saint George, a fine golden

yellow. White Themis, a new sport; fine as the old goddess herself. Julia Gris, a splendid bloom, which will vie with the Christinas at the exhibitions; a transparent peach colour, or peach suffused with lilac; a grand thing. La Belle Blonde, a large blush white. Lord Ranelagh, orange red running into salmon, "turned up" with golden yellow. Mr. Broome, in commemoration of the finest qualities of a fancier, as they have been exemplified in the ways and works of the godfather of the whole family in the Temple Gardens, and in the centre of London; a fine large lilac fully incurved. And Edith Dombraine, a true French white flower of striking beauty and novelty; very pretty ladylike thing, and the young lady herself could hardly have picked out a better namesake in the collection.

The next move includes all I could see of the new Pompons for next spring; they and the best of the old ones occupy a house by themselves, which is a better arrangement for comparing and criticising them. Lucinda very good indeed, and a new colour made out of rose and lilac; a very full flower. Ais, very pretty after Model. Capella, dark red chestnut, and very free bloomer. Orange Boreen, a new style, a Pompon incurving up its developed florets; it is a dark reddish-orange. Citronella, pure citron colour, and very free habit; also incurved. Senus, a dark red orange destined for combat at the exhibitions. Brezen Mirror, a shot-silk-like cast over its brassy vase, which is round as Bachelor's Buttons. Apollo, a hybrid-chestnut red tipped up with orange in the style of Auguste Mié, a dwarf plant and free bloomer; and Medora another hybrid of a rosy lilac colour. Four or five years back I noted a novel departure from the normal type of this family from this same nursery, in a kind called "Yellow Fringe," a seedling of 1852. I inquired after it, but could not now find it in the collection; but Mr. Salter promised me the "Yellow Fringe" would be forthcoming, and when that comes I shall show you how the Japanese obtained the Dragon section, which Dr. Lindley figured this last summer. Louis Bonany has already the Dragon, or rather the Stag-horn, more in the mouths of half the florets; and there is a third kind in which the ends of the straps of the florets run stag-horn fashion.

The misfortune is that our florists fight against Nature the moment she freaks into novel forms and queer shapes, and confine us within the confines of the carpenter's compasses. But the following is a recast of Pompons from the older lists, all of which are of first-class merits as pot plants for private or public occasions. Florence, bright rose, and free bloomer. Reine des Anemones, pure white. Calliope, bright-red Anemone. Miranda, rose with silvery edges. Miss Talford, white. Cronatella, yellow. Tropheé, mixed rose and lilac. Justine Tessier, sulphur. Christiana, yellow, with brown tips. Andromeda, cream, with brown points. M. Van Houtte, chestnut and orange. Ida, clear yellow. Sultana, dark rose. Musidore, a Liliput of chestnut colour. Diana, white. Lara, rose-tipped cherry. Miss Julia, red chestnut. M. Eugène Domage, white. Mrs. Turner, white hybrid. And Madam Sentir, the most generally liked by ladies of all the Pompon race, except the pretty little honeycomb dear, called Reine des Anemones, which is a month earlier than Madam Sentir, which Mr. Salter calls a perfect gem.

I would stick faster to the following kinds of the big Chrysanthemums than make up my book from the reports of the exhibitions:—Jardin des Plantes, of which you heard enough for one year. General Hardinge, large Italian red. Alfred Salter, large rose. Golden Queen of England and the Queen of England, rose, to light blush. Pégase, dark purple. Bouquet des Fleurs, dark red chestnut. Cassandra, all shades of blushes. Julie Lagrave, a dark red Anemone. Novelty, the largest blush you ever saw. Wonderful, the best purple in the family. Sulphura supra explains itself. Léon Leguy, bright rose. Versailles Deliance, ditto. Aimée Ferrière, silvery white, tipped or mottled with cherry. Alma, a dark flower of great substance. Dr. Rosas, dark rose. Miss Kate, delicate peach, and changeable as a blush. Fétide Polaire, large bright yellow. Marshal Duroc, mottled, rosy lilac. Gluck, the earliest of the Anemones, and the largest yellow of them. Nancy de Semet, pure white Anemone, old as Annie Salter and Yellow Perfection.

Nothing was ever done less wise than to have driven the tasselled Chrysanthemums out of cultivation, for in them we had the blood and the germ of a new race to vie with the best of the German Asters. I recollect when the best of them were mere tasselled weeds of no account; but there is one old Chrysanthemum yet, and it is in this collection of Mr. Salter's, from which a race of German-Aster-like Chrysanthemums, might be got

if the Guernsey seeders could hit on the strain. The name of this is *Marfonna*, a large, bold pink flower.

Globe-flowered ones, round as cricket-balls, will soon be favourites with the public, *Gauides Rose* is yet the best of them. If some insist on all being incurred, the game will soon be up with them, as it was with the sale of *Pelargoniums* just at the time of the appearance of the French spotted sorts, from which a little variation is still obtained. Mr. Salter is well aware of this, and he arranges his winter garden differently every year to make a change.

In looking over for noticeable plants among this part of the collection, I made a discovery of which I am more proud than if I had hit on a new comet, and the reason why I am so proud of it is this. I heard that Mr. Moore, the Secretary to the Floral Committee, had been recently over the collection, and Mr. Moore is known to know more about Ferns than I do of *Geraniums*. Yet I found the newest and one of the best Ferns in this world in this very collection after he did not see it. You might call it, so to speak, a tree of *Pteris argreca*, but then it has no stem and cannot be a tree. The leaves of it, however, are from 3 feet to 5 feet long, and the footstalks of the leaves are bare as a brazen fag the full length of 3 feet. The plant is the most splendid one that ever I discovered among Ferns, although I have slept on new beds of them for whole months at a time—that is, at bedtime. The *Centaureas* have been increased two kinds since I was there before. The *Centaurea ragulina* is an improvement on the style of *Cineraria maritima*. *Centaurea gymnocarpa* is made into low standards, and *condidissima* is rooted from a fry of young side shoots in three weeks, in sand under bell-glasses, kept dry and cool the first fortnight, then plunged in heat they root at once. But when you have a stock of them, the easiest way is to keep it up by making summer-out-of-door cuttings of the large shoots, which root as freely as Punch, only they take a little longer time to do it.

The big-leaved plant I noted there last year, *Wigandia caracasana*, which "D." of Deal, saw in bloom so much about Paris this autumn, has also flowered at Hammersmith with Mr. Salter in long branching spikes. Some fine *Cannas* are kept for the same exotic looks out of doors, *gigantea*, *discolor*, *indica*, and *zebrina* are well suited for such work. But is the *zebrina* of continental gardens a real *Canna*? The Doctor should see to it, for we have it as such under his authority; but under my authority, which is no authority at all in the case, the plant is no more a *Canna* than I am, but the old *Maranta* or the less old *Calathea zebrina* and nothing else. There is also a stock of several other exotics, as represented by *Caladium esculentum*; *Astelia Banksii*, a rare good old thing; a greyish-silvery, soft *Pitcairnia*-looking plant with long leaves ending in longer whipoards, and throwing up the flower-spikes as Pine Apple plants do, from the centre of the old parts of the plant. Variegated *Yuccas*, and Bamboo-like Grasses, and Variegated Ivies, of sorts; *Araucarias*, Orange trees, *Camellias*, and very fine *Myrtles*.

There is also in the winter garden a new *Begonia*, which brought out some of the natural history of the Floral Committee, who could liken it to nothing so much as to the ears of the elephant, while in reality it is the very image and likeness of the old *Saxifraga ligulata* multiplied four times in the four ways from the centre. This will soon figure among fine-leaved plants.

Mr. Salter has been among the *Snagdragons* for a long while, and his stock of them is very large and select as well as curious. His collection of variegated plants is the richest in kinds of all I know, and his herbageous border and rock plants would puzzle one to know where they all came from, and he is constantly at work on the fancy Pansies, fancy *Daisies*, and the new fancy *Pyrethrums*, at which he has been lucky for many years.

D. BEATON.

A FEW DAYS IN IRELAND.—No. 6.

MR. WILKIE'S, PHENIX PARK.

EACH age is generally marked by some peculiarity and distinctive characteristic of its own. Some mode or custom becomes so fashionable, that everybody must pay court or homage to it, or be looked upon as singular and eccentric, as a pretty young lady would now be considered, were she to appear in genteel circles wearing one of those coal-scuttle bonnets that were all the vogue among the *belles* in our boyish days. To this general rule as respects customs and fashions, gardening has been no exception. It, too, has had, and still has, its manias and its

favors. We may smile at some of the doings of our predecessors in this attempt to reach the heights of perfection in matters of refined taste; but we may also rest assured, that our great and wise doings, and our attempts to combine the natural, the beautiful, and the useful, will just be as well laughed at by our more advanced descendants. Looking at the matter calmly, however, we shall find that instead of passing over the doings of the past with the sneer of contempt, it will be wise policy in us to note, that the peculiar systems adopted were just peculiarly fitted to the times and the circumstances that brought them into action.

For instance, when our country was too much clothed with natural timber, there was so much of the romantic and the picturesque, that man who always likes his labour to be seen and his work appreciated, could only do so by introducing straight avenues into his park, straight walks, straight terraces, and straight walls and hedges into his garden, and then develop the purely artistic still further, by clipping and training evergreens into all sorts of shapes, having some resemblance to birds and animals, and pans and kettles for ultimately developing his cooking capabilities. Then, again, when circumstances were changed and the forests in great part disappeared, and regular fields were laid out, and straight hedges and hedge-row timber gave something of a regular geometrical character to the appearance of a country, just merely for distinction sake and the law of contrast, picturesque scenery began to be introduced into our parks, and groups of trees were thus formed, so that a distinction might be made, alike from the massive forest and the single filed hedge or avenue, and this was carried so far that sweeps and curves were often made near mansions where straight lines seemed from the nature of the case to be demanded. In all such circumstances there was a reason why the art employed should at once be seen and acknowledged.

Just so with the mixed flower garden style, where shrubs, and Hollyhocks, and Dahlias occupied the centre of large beds; and lesser shrubs, and lesser flowering plants came down to the outside, and thus presented something generally pleasing all the year round, and is anything but despicable now. Until large masses of flowers in woods and glades gave the idea of the bedding or grouping system, and the fringing exotics to give rich massive displays in summer, which is certainly very beautiful and striking in its effects, and just now in the very blaze of fashion. Like the other systems we have alluded to, it has the recommendation of telling that the hand and the brain of man have been there, as Nature, which some people tell us we are to imitate, could never have produced if left to herself, such masses of contrasted and shaded colouring. In all these cases gardening has been an art of design, design intended to be seen and not concealed, and the seeing the effects of which are the chief recompense for the toil and expense involved.

Striking as the bedding system of flower gardening is, it seems now to have reached the zenith of its fame. The mind longs for change—it pants after a massive background to throw back the dazzling colours; and amid the bewilderment of such splendour it sighs for the relief of light and shade instead of level massive gorgeousness. Everybody may act the prophet now-a-days, and so we may out with our vision of the future as respects ornamental gardening. First, there will be the breaking-up of the level monotony of many flower gardens; then there will be the introduction of suitable backgrounds to these gardens, and the not leaving long ribbon-borders exposed in the middle of an open lawn; then there will be the grouping of elegant tapering evergreen shrubs, not in the flower-beds, but forming part of the group, as so many relief-stand-points to the eye, and as so many means alike to enhance and relieve the masses of colour; and, not to enlarge, by-and-by there will be such a general safety as to colour, that beauty of form will be sought after as a desirable relief, and equally showing proofs of design.

The evil most likely will be, that just as in the case of cockle-shell bonnets and unapproachable hooped petticoats—we approve of hoops if at all moderate)—each of these modes, like those which have preceded them, will be but too generally followed. Our wish would be that then, and also now, each individual would have the courage to carry out his or her distinct comprehension of the beautiful. If a person lives long enough he will be sure several times to be a leader of fashion even without knowing it or caring for it; just as the worthy mechanic who took such care of his marriage coat that he wore it every Sunday afterwards through a long life, and left it a good coat after all, found that several times the whole of the people of the neighbourhood imitated the cut and the pattern of the valued

garment. Were this individualism carried out, instead of the mere following of the prevailing fashion at the time, we should find ancient styles made modern again, even to the clipping Yew and Box into swans and peacocks; we should find flowers in many different arrangements most common at one place, and trees and shrubs the chief peculiarity in another pleasure ground; and when one neighbour visited another there would be something more exciting in this department than merely comparing Calceolarias and Scarlet Geraniums with those he had at home.

These ideas, and others of a kindred character, swept through our mind as, in company with Mr. McNeill, we entered and traversed the small pleasure ground of Mr. Wilkie which we noticed in passing the other week. Perhaps a great part of the charm was in finding something so unique and different from what we might have been led to expect. For much personal kindness we are indebted to Mr. Robertson, of the firm of Dickson, Hogg, & Robertson, the eminent seedsman of Mary Street, Dublin; and if these gossiping articles convey only a small portion of the pleasure to the readers that we have experienced in writing them, then these readers too are indebted to that gentleman for furnishing us with instructions so as to enable us to see not a tittle of what was worth seeing, but as much as we could manage in our limited time. Well, on our card was written, "Don't miss seeing Mr. Wilkie's." And on the way from the regal lodges, with their great ranges of glass, their fine crops of fruit, their fine specimens of plants in pots, and their myriads of bedding plants, we could not help wondering if we were going to examine some smaller, but similar edition at least, of ornamental gardening: therefore the surprise was all the more delightful on finding that there was no glass with the exception of that in the cottage windows—hardly any softwooded flowering plants at all—few even of gay-flowering shrubs, with the exception of Roses, Jasmines, and Honeysuckles on the walls of the house, Clematis flaunting from rustic columns, and Lilacs and mock Oranges, &c., in the boundary shrubberies; but that the great attraction was a collection of some of the most showy exotic trees and shrubs that would flourish in the climate, and arranged in the most tasteful manner without any attempt at classification.

Now, mark the propriety of such a decision. If Mr. Wilkie had set apart a good portion of his lawn for flower-beds, merely to be in the fashion, he might have excelled here too, as we tell some people with little gardens, that if they have a single flower-bed better than any one of ours, they just beat us in flower gardening. But, then, in massiveness of display Mr. Wilkie could not hope to equal his neighbours; but now they come to him to admire a distinct form of the beautiful which they themselves do not possess. Again, with such flower-beds, there would be no end of trouble, in getting plants, and saving plants, whilst these beautiful trees when once properly planted, can take care of themselves, and every month and every year will be increasing in their attractiveness once more. These trees from their exotic character not only constitute a distinct feature, when contrasted with the great Park, but they are peculiarly appropriate in the little lawn of the Superintendent, not only for gratifying his own taste and enthusiasm, but for showing to his neighbours and those who are now the representatives of royalty how that splendid Park can be made even still more interesting.

We have noticed the taste displayed in this little lawn. This depends greatly on the diversity of the arrangements. We wish we had obtained the exact size of the garden: but it is made by a little intricacy to look much larger than it is. The widest part is just as you enter the gate close to the cottage, where a fine Wellingtonia meets the eye. Beyond the cottage a winding walk with shrubs on one side encircles the lawn; the lawn being kept in the middle, but separated from the walks by raised banks, which advance and retire, so as to prevent you seeing much of the lawn at one time, and at each turn presenting you with a fresh view. On this lawn many of the finest plants are growing in the gardenesque style, with their lower branches sweeping the grass. On the raised banks they are allowed both deciduous and evergreen to blend in the picturesque style. You turn this corner and then another, and you are presented with fine specimens of the wild picturesque, in the shape of lofty stumps of the boles of trees, with the Glycine flaunting from the top of one, and the Clematis with its almond-scented flowers dangling from another, whilst close to the base you may find a basket made of tree roots, rimmed with Ivy, and decorated with Ferns and alpenes.

Look into this bend and that nook and you will get a dash of the romantic, in a rockery and fernery, with a great variety of foliage for background, and lighted up with plants on the crest of the white-flowering Clematis and the elegant Pampas. Some of which on the lawn last season had a forest of flower-stems averaging 12 feet in height, and which have suffered little or nothing, whilst ours were next to destroyed last winter. Is there nothing of the simple, almost naturally artistic? Aye, that there is, in some fine tazzas near the cottage, which seemed to be 6 feet of the root-end of a large tree above the ground, and supporting a huge protuberant root. All hollow some 12 feet or 15 feet in diameter, with rings of Ivy and Clematis fringing the edges, and the interior parts devoted to flowers, which tazza just wanted more breadth at the base to make it elegant indeed. "Nothing more purely artistic?" Well, yes there was, not in the shape of some Tuscan vases near the door, not in the appearance of a couple of Phoenixes, cut out of Box or Yew, which we would have admired; but in the appearance of sundry wire stands—very nice for those who like them, and with a trim little cage for each separate red pot with its flowering plant to stand in; but we shall say nothing about them, further than that the boisterous wind, that then became very squally, turned almost every stand topsy-turvy, and sent the pots and the plants in their sprawling in different directions, and we were not at all sorry to witness the catastrophe. Reader, if with all your moralising you have ever experienced a singular feeling, we leave you to say what, on detecting some slight flaw or speck on a work of great beauty, then we feel you will forgive us.

We do not recollect noticing a single plant that bore the marks of being injured last season, except an elegant specimen of the Abies morinda, all the rest were green and flourishing, and more distinguished for that and massiveness of growth, than for their mere height. We have already noticed the Wellingtonia, an elegant plant, 9 feet 3 inches in height, and 7 feet 9 inches in diameter of head at the base. Taking that width as a means of measuring the width of others, we will subjoin a few of the most striking specimens on the lawn, merely mentioning their height:

Abies cephalonica, 24 ft. high	Juniperus excedens, 13 ft. high
A. Douglasi, 26 ft. high	J. recurva densa, 17 ft. high
2 Cedrus deodora, 24 ft. high	J. pendula, 10 ft. high.
C. atlantica viridis, 18 ft. high	Libocedrus chilensis, 8 ft. high
Cryptomeria japonica, fine	Picea nobilis, 14 ft. high
Cupressus elegans, fine	P. pinaster, 13 ft. high
C. funebis, 12 ft. high	P. Nordmanniana, compact plant
C. Goveniana, 15 ft. high	P. Webbiana, 11 ft. high
2 very fine C. Lambertiana, 22 ft.	Pinus cembra, 11 ft. high
Ditto C. macrocarpa, 17 ft. high	P. excelsa, 13 ft. high
Ditto C. torulosa, 17 ft. high	P. insignis, 17 ft. high
Ditto C. sempervirens, 20 ft. high	P. taurica, 15 ft. high

This last Mr. Wilkie deems quite true, and it is a beautiful compact specimen, somewhat resembling a very close stunted specimen of Pinus austriaca. On the lawn is also a fine Weeping Ash some 12 feet in height, the branches sweeping the grass, and leaving a cool retreat inside of 24 feet in diameter.

On the banks in the mixed style were fine plants of *Ailanthus glandulosa*, used for feeding silkworms in France—

Acer colchicum, 17 ft. high	Paulownia imperialis, 16 ft. high.
Berberis Darwini, 10 ft. high	(In flower-bud, but has not flowered.)
B. japonica, fine	Quercus pendula, 21 ft. high
Cephalotaxus Fortunei femina, 8 ft. high	Saisburia adiantifolia, 8 ft. high
C. Fortunei mascula, 8 ft. high	Pyrus scabra vitifera, or something like that; a fine-foliated sort from the Himalayas.
Cupressus Bedfordiana, 6 ft. high	Taxus japonica, 4 ft. high, fine
C. mexicana, 15 ft. high	Tilia europaea grandifolia (a fine-leaved Lime, synonymous, we presume with platyphyllo).
Helix latifolia, 9 ft. high	Larix dahurica, 7 ft. high
L. nigra-sevens, 18 ft. high	
L. pedunculata, 7 ft. high	
Juniperus oxycedrus, 8 ft. high	

and fine plants of the *Ulmus montana pendula*, or Drooping Weeping Elm, which would look handsome on large lawns.

These are only a few of the many objects of interest. There are a great number of small shrubs, alpine plants, and Ferns, some of the rarest of which we were to have a list of, but we presume they will now be left for another visit.

There is one more interesting feature in what may be termed commemorative or monumental plants, such as a nice plant of the *Picea Nordmanniana* planted by the sons of Robert Burns, the Scottish poet; a plant of the *Thuja borealis*, 6 feet high, planted by General Lord Seton, in 1860; *Thuja gigantea*, a beautiful plant 73 feet in height, planted by the Earl of Carlisle, in 1858; *Thuja borealis*, 6 feet high, planted by the late Countess of Eglington, 1859; a *Wellingtonia gigantea*, 6½ feet, planted by the late Earl of Eglington, in 1859, &c.

Alas! that in these latter cases these pretty plants should so

soon be monumental. It is sad, sad, when the ennobled by Nature, as well as ennobled by birth, noble in action, noble in effort to leave a world better than they found it, are thus taken suddenly away in the vigour of their strength, and the full flowing tide of their usefulness. Would that we could all live so as to be really missed when gone.

But we must stop. Going from such trees commemorative, we might pass on to consider them in their grandeur, as suggestive of studies in history and geography, until we could almost fancy we had crossed the Pyrenees, climbed the sides of the Andes, and trod the snows of the Himalayas; but we have said quite enough, without telling many amateurs the course which we must follow, to lead them to see even from this one example of a little lawn, that there are many modes by which they may cluster vegetable beauties around their homes, without slavishly following what may just then be all the fashion. R. FISHER.

ERRATA.—Page 151, 2nd col, fourth line from bottom of last paragraph on pits, &c., the word "surtnce" should be "firnace." At page 150, 131, figs. 3 and 4, I must suppose that bricks are left jutting out in the side walls for platform, as No. 1.

THE IN-DOOR PLANT CASE.—No. 3.

(Continued from page 147.)

I WILL NOW proceed to give a few details, of ways which I have found useful of growing plants and forcing flowers in these small glass houses.

The arrangements I have found most successful have been elsewhere described; the actual culture, therefore, is the point I have now to mention more particularly. The objects of the cases vary of course with the different plants grown in them: warmth with some, moisture with others, protection simply from dust and smoke with others; and, perhaps, with all, the great advantage of a screen from dry air, gas, east winds, and a smoky fog.

It is thus that for stove plants; for raising seeds and cuttings; for growing on in summer the flowers that thus are raised; for growing bulbs in the greatest perfection possible, and for flowering them in a way that it is rare to see surpassed as to size and duration; these cases act in the most diverse manners.

This chapter I propose to devote to bulbs, as they are at present claiming so much attention.

We will now, therefore, proceed to fit up a four-foot case with a grand winter garden; and, as to time of flowering, if my directions are carried out on the 1st of September they afford every hope of a splendid display at Christmas; while a month later would probably produce a still finer show in January, the very early flowers being seldom the best grown.

For a late succession, perhaps in March or April, the bulbs require potting in the driest sand, keeping in a place that is perfectly cool and dry—entirely in the dark; and, after careful watching all through the earlier months; (since if bulbs will grow nothing but mischief is to be done by stopping them); they take their turn exactly like the others about December, or early in January. These hints though not belonging expressly to plant cases are most necessary, notwithstanding; as nothing is more hopeless than an attempt at growing ill-conditioned bulbs under glass at all. The bulbs being then provided in a healthy state, the tops not shooting out before the roots; the pots to contain them should be filled to a third of their depth with broken charcoal, the hole below being covered with a zinc cap or an oyster-shell. The soil (just good common loam mixed with a little sand) should be put in lightly, nearly to the top; three bulbs then being taken of each selected sort, they should be so arranged on the surface as neither to touch each other nor yet the flower-pot, the bulbs just resting on the slightly-moistened mould—it must not be wet; and, then dry sand being poured in round the bulb, the soil is filled in lightly to the top, as high at least, as soil ever should be filled—that is, at least to a half-inch below the rim.

The great object is now to keep the bulbs dark; I have

heard people recommend turning flower-pots upside down upon them, and stopping up the holes; but that, I own, seemed to me a very damp-trap. Many persons place them, as I do myself, in a dry cellar (guarding them well from mice which nibble off the roots), and others again passing through town, or at home for a few days early in the autumn, plant a case entirely; and, having placed it in a quite dark room, or covered it up with a thick cover through which no light can penetrate, they leave it quite to its own devices till six weeks later they come back and find white little points appearing. This is a very easy and effectual mode of setting to work at first. The box should then be filled with white sand to an inch above the hot-water tank, and the whole set of pots or dishes, glasses, or bowls, should be placed thereon. The top and slide glasses should be taken out, and, if the room is not dark, a cover put over it of sufficient thickness to exclude the light entirely.

It should be always remembered that a little light is the most dangerous things for plants; where light is excluded there should be total darkness. A glimmer of sunshine through a chink in a window shutter makes most woeful havoc.

The pots being then duly planted, whether with Hyacinths, Tulips, Scillas, Snowdrops, Narcissi, or Jonquils, the case being left open and all in darkness; in from four to six weeks it will be time for a new arrangement.

The full bright light being admitted gradually at first, the sand in which the pots stand may be a little watered. I have a favourite mode of watering the sand by means of an inverted flower-pot, through the hole of which the water is poured down to the bottom of the case to be sucked up gradually. After the first day or two, however, the sand may be kept quite wet.

If the weather is damp or foggy it is sometimes desirable even in November to give a little heat, just to make the air circulate freely instead of hanging in a stagnant manner round the growing plants. The heat should in these instances be always given in the lightest time of the day; and both the front and top, at any rate the former, should always be then kept out. Indeed, even as a general rule, if a case stands near a window, I think, while bulbs are growing, the side is as well kept out.

It should always be considered that good roots are the first essential for obtaining fine flowers; and if the roots are deficient the flower will most likely be weak and lanky, the bulbs going all to leaf. Darkness especially, or too much warmth, is apt to end in this way.

The less heat then the better till the flower-buds are fairly developed. After that a case nearly closed, and a soft moist air, produce flowers far better opened and in more dewy freshness, than any that I remember to have elsewhere seen.

The heat should not, however, be given except in daylight. The flowers should be kept a full inch from the glass; and a vigilant watch should be kept in order to remove any falling leaf, or any decaying petal, when the blossoms open. There is one special thing to remark also in the care of these cases—that any vegetable substance not in active growth not only decays itself but speedily infects everything that it touches. I have known a Primrose blossom falling on a branch of Begonia cause the whole spray to decay entirely. A single Myrtle leaf even, will do a great deal of mischief. But these things only require watchfulness: five minutes' attention daily is enough for the avoidance of all such disasters, and it is not less conducive to fresh and brilliant beauty than it is to health.

I consider four or at most five pots of Hyacinths or Tulips amply sufficient for such a case at one time. A few little groups of Scillas and of Snowdrops may also be most favourably introduced amongst them: these will grow beautifully in between the pots, just dropped into the moist sand. During the whole time the more air

that can be given at one side only, the better for the plants. During the very few last days when they are forcing hard, 75° to 80° is not too great a heat, provided always both sand and air are moist, and that the plants are in full light. After the blossom is once open I have found a drier atmosphere, a very much cooler temperature, and a raised top, the best conditions for preserving flowers.

It has been already remarked that no flower must ever touch the glass; its own evaporation, with the condensation, destroys it at once. Even the leaves are better warded off. In some instances I have even found sad injury to arise from using gathered moss for covering the pots. Healthy growing moss, such as *Lycopodium denticulatum*, answers far better for making the surface green, without doing any injury to the other plants and flowers.—E. A. M.

CUTTING DOWN VINES IN POTS—HEAT THEY REQUIRE.

I HAVE purchased a quantity of Vines in pots, they are from 10 feet to 14 feet long. Should I prune them down to a certain length, or let them fruit as they are? I should also feel obliged by your stating what heat they will require (they are Black Hamburgs).—NEMO.

[Your Vines in pots being from 10 feet to 14 feet long, you should have said whether they had made this year's shoots the entire length, or have they borne a crop of fruit and have lateral shoots or spurs. The first state is the best, and we will suppose that is the state of yours. Then, again, you should have stated the strength they have attained to; we must, therefore, guess at that also. Vines are not certain to show bunches unless they are pretty nearly as thick as a man's little finger, and the wood should be well ripened a good brown colour, with every bud visible and prominent.]

If your Vines are in such a state, then you should cut off only about one-fourth of their length, but if the upper part is not quite ripe, and the wood solid and with very much pith visible, then cut off one-third of their length. Prune them immediately, and do not begin to force them for at least a month after you have pruned them. Six weeks would be better, because if cut and put into heat immediately they would certainly bleed at the top. Begin with a heat of not exceeding 15° the first fortnight, and increase 5° every fortnight till you reach 65° by night, and 70° by day. This gradual increase of heat will cause every bud to break on the last year's shoots. If, however, the buds on the lower parts of the shoots do not break or show signs of pushing, then bend the shoots backwards in a bow-like manner. Indeed, many growers adopt that precaution always which is a practice that it is wise to follow. It checks the sap from rushing in such force to the highest buds. Keep your Vines syringed at least every other day, and also keep a moist atmosphere up internally. It encourages the buds to break kindly. As soon as the bunches are fairly visible stop each lateral one joint above the bunch, and all that are barren—that is, if any do not show a bunch rub them off entirely. You will thereby throw all the strength of the Vines into the fruitful branches. Should you be so unfortunate as to miss having any bunches show on any of your Vines then stop every lateral excepting one near the base of the shoot. Train that up, and when it has attained leaves and a shoot 2 feet or 3 feet long then cut all the rest away and encourage that shoot to make a good one, by giving manure water occasionally to strengthen it. It should make you a good, strong Vine for the following season. Let us hope, however, that every Vine will bear you some fruit. We should be glad to hear of your success.]

ELANELLY HORTICULTURAL SHOW.—We cannot allow this praiseworthy exhibition to be an exception to our rule not to report local meetings, although Mr. Bird, of Chrysanthemum celebrity, has sent us his notes, and adds, "Among the company I saw ladies, both elderly and young, wearing the pointed-crowned, sugar-loaf hat, about 15 inches high, with brims 5 inches or 6 inches broad, and tied under the chin by a black ribbon."

WHY THE COLLAR SHOULD NOT BE BELOW THE SURFACE.

BUDDING APPLE TREES—PROPAGATING VERBENAS.

EVERY book on gardening that I have read warns one against placing the collar of the tree in planting below the surface of the soil, but none of them has informed me of the reason of this. Is it that the bark which has been above the soil is injured by the wet when placed below it?

Falling this spring in grafting some Paradise stocks, I tried budding them, and the buds have taken, with the shoots from these at the end of next year be as vigorous as those from grafts inserted next spring? It is not usual to bud Apples.

Tell me the essentials in propagating Verbenas. For several years I have lost three-fourths of my stock in winter, but fancy that I have ascertained thus much, that the slips should be from short-jointed shoots, be struck in a cold frame, and in winter kept, if possible, without fire heat.—WYE-SIDE.

[The collar of a tree is that part of a plant whence the root descends into the earth, and the plumule or stem mounts upwards. As Nature points out the practice, we must have strong reasons why we should act quite differently. Many forest trees are thus injured because the roots are placed deeper than they ought to have been, and raising the earth against the stems of trees not only impairs their beauty, but often kills them outright. Some trees so deeply planted will send out roots from the buried stem; but in the case of fruit trees, that is often attended with prejudicial results. It is generally better to have only one set of roots. If you consider that most gardeners would prefer a young Vine raised from an eye or bud, to one raised from a layer, you may see a reason why stems should not be buried. This subject will come in our way ere long. If the tree is an ornamental one, there will generally be a swelling at the collar, which forms, as it were, a base to the column or bole, and deep planting destroys that, and thus deprives the tree of a base to stand upon.]

Many propagators prefer budding to grafting, though in low dwarfs there is not much gained in time.

Another cause of success in striking Verberna cuttings, besides those you name, is having the cuttings struck in time, so as to be hardened off before winter, then they will keep well in cold pits. But in severe weather a little fire heat will be a help in keeping off mildew, &c.—R. F.]

POTTING VINES AND THEIR CULTURE.

I HAVE about a dozen pot Vines, which are now in the pots they have made their season's growth in, and have just shed their leaves. I want to begin forcing these Vines early in January. I have a trough prepared for them in which I purpose fruiting them.

I have pruned them as required. When ought I to plant them in the trough, and what compost would you recommend?

I have thought of putting them into fifteen-inch erinoline (wire) pots, 15 inches in diameter, and deep, so as to enable them easily to strike root into the soil around them; and at the same time in the autumn by pruning all the roots which appear outside the pots to remove the ball of roots intact, and give them a season's rest and again to fruit them. I have also some pot Vines I want to repot to make another season's growth before fruiting. When should this be done?—GREYFHAES.

[The Vine, like every other fruit tree, is injured by the rust of iron: therefore, we cannot recommend you to adopt erinoline-wire pots to put your fruiting Vines into previous to plunging them into your trough or narrow border. No doubt if you lift out again with a ball of roots they would push stronger than if they were lifted and potted without any ball. You had better, if you will go to that trouble, order some potter near you to make you some pots from 12 inches to 14 inches diameter, with holes at the sides; or, what is better still, with slits at the sides. Such are used by some Orchid growers. After they have fruited you may lift them, repot them, cut them down, and train one shoot during the following year to fruit the year after. Vines in pots seldom do any good for fruiting after the first year's crop unless they are cut down and have a year's rest to grow a single rod to fruit the second year.]

After you have potted your Vines in such pots you may plunge them as soon as you like in your narrow border, which is, we suppose, wide and deep enough to hold the pots and a little

more. The compost to fill under, around, and above these pots should consist of year-old turf, well chopped, three parts, rotten dung one part, and as much of rotten leaves if you can get them, adding about one-eighth of small pieces of charcoal. The whole well mixed together but not sifted, a layer, 2 inches thick, of broken bricks or broken garden pots should be placed at the bottom of the trough to carry off the superfluous water. As you have pruned the Vines you may start forcing in January; by that time there will be no danger of your Vines bleeding. As you have a dozen Vines ready to fruit in pots in the trough or border, would it not be as well if you were to commence first with half the number, and the other half a month afterwards, you would then have a succession of Grapes, and the second batch would stand a better chance of doing well because then the days will be lengthening and the natural heat increasing?

The Vines you allude to that you wish to grow this next season to make fruiting plants the following season, are, it must be presumed, year-old plants. Pot them in large pots directly in rich compost—viz., turfy loam, rotten dung, and leaf mould; place them in a house where no frost can reach them, cut them down to three eyes, and here they will soon begin to push new roots, and thus gain strength to push forth strongly in about the middle of January, when they should have a gentle heat given to them, and be grown on through the spring months. By thus starting them early you will be enabled to ripen their wood early, and so have a more certain prospect of obtaining a crop from them the following season. See answer to "NEMO" to-day for further information.]

CEMENT FOR POTS—BOXES FOR CUTTINGS.

I AM growing some Cinerarias, in a sitting-room, on the plan recommended lately in THE JOURNAL OF HORTICULTURE, of placing one pot within the other, and cementing them together at the top, and I should be glad if you could inform me what is the best kind of cement to use for the purpose. I do not like either of those suggested by Mr. Beaton—putty or grafting-clay—I am about trying the red cement used by philosophical instrument makers. This is very easily made—four parts of resin and one of beeswax, melted in an oven or by the fire in any earthen vessel not liable to crack with the heat; when thoroughly melted another part of venetian red is carefully and gradually stirred in; it may then be poured upon a dish, on which a little grease has been rubbed, and as it cools cut up into sticks. This is always ready for use, as it simply requires melting by a candle, and applying like sealing-wax; this does very well now, but how will it bear the heat of a midsummer sun in a greenhouse? I have my fears of its melting under this ordeal and quietly letting the inner pot sink to the bottom of the outer one. If this fails how will Roman cement do? Will it be so adhesive that the pots will most likely be broken in separating them? Or, will mixing an equal quantity of finely powdered brick, so as to make the cement resemble in colour the pots, prevent its causing them to adhere so strongly as to be broken in separating them? If Roman cement is approved of, how should it be mixed and applied, as I doubt not many will be trying a plan recommended by such an authority as Mr. Beaton? I think information on this point will be acceptable and useful to many of your readers.

What do you think of the following modification which has suggested itself to me of the "tops and stops" for striking cuttings, recommended by Mr. Beaton in your Journal of October 1st?—

Instead of pots, I get from the grocer raisin or currant-boxes, about 20 inches long, by 8 inches wide and 7 inches deep. Box No. 1 contains the cuttings; box No. 2 has the bottom knocked out, and is inverted on No. 1, the place where the bottom has been is occupied by two or more squares of glass; the sides of the upper box afford shade, the glasses can be moved so as to give air, as the cuttings are able to bear it until they are removed altogether, and at last, the upper box also. In the case of flower-pots, something like the circular drums or boxes containing Figs, without tops or bottoms (the latter being supplied with a moveable square of glass) would answer the same purpose. I imagine such cylinders of wood could be supplied for a small sum per dozen, and if the pieces of glass to cover them were cut in a hexagon or octagon form, they would occupy no more space than bell-glasses, would be twice as durable, and, I should think, half the price. A word to the wise is enough:

and I shall hope to see some of your commercial readers taking up the idea and advertising some such contrivances, in sets of a dozen, of different sizes, fitting into one another, with the glass coverings packed by themselves; they would occupy very little space, and, I should think, might be supplied at 5s. to 10s. per dozen, according to the size, with profit to the vendor. Cuttings thus protected, and especially double potted, as recommended, might be placed amongst plants requiring abundance of air, no small advantage where room is scarce.—COURTNEY CURATE.

[Wood, in any shape, is not fit for putting cuttings in, as in pots and pans, save in the height of summer, or for the convenience of keeping so many common things in winter. The best contrivance of the kind is that by Mr. Walton, to supplement his case—that is, a "cold box" or a packing-case, deep enough to hold all the sizes of propagating-pots, long enough for what is to be done, and not wider across the mouth than a piece of sheet glass can cover across. That is a regular omnibus for seedlings in spring, and for cuttings during seven or eight months in the year. I described my own cold case, and how I did it, two or three years back.

There is no cement of any kind that is one-tenth so good for my plan of double potting as a raw piece of a clay clod. That is just what I use myself, and I would challenge the whole range of the sciences to produce a composition more effectual, or one-half so good or so cheap. My double pots and saucers are as free as my tea and coffee cups, and are just as freely changed or "put by" or brought out, and arranged or rearranged as often and as quickly the one as the other. I suggested grafting-clay, instead of the natural lump (from which I supply myself, as giving some degree of trouble, or common putty, as costing something, because few care for things which cost nothing).—D. BEATON.]

PLANTING VINES IN POTS AND OUTSIDE BORDERS.

HAVING lately purchased some Vines, strong canes, capable of bearing fruit next year, I should be much obliged for directions as to their culture in pots, grown exclusively in pots, not as for orchard-house culture, where the roots are allowed to grow through and outside the pots. What sized pots should they be grown in, and what compost? When should they be transplanted into these fruiting-pots? What after-culture will they require? My object in growing them in pots is, that I have just erected a large viney, and the Vines intended for it are to be planted in a border outside of the house, and as they will, of course, not come into bearing for some time, I wish to take what advantage I can of the house, and have a crop of Grapes from Vines in pots, which pots will be placed on the stage round the house. I do not wish to spare the Vines, and as they are very strong canes 8 feet at least in length, I hope to get from six to 7 bunches from each next year. What time is the best in this locality (county Waterford) for planting permanent Vines in an outside border which faces south-east, and well sheltered from north winds?—M. C.

[For reasons often given, we would not advise you to shift or do anything with your Vines in pots now, if the pots are of any size—say from 12 inches to 16 inches diameter, which we presume they are, since the canes are so good. Had it been July it might have been different. You may scrape off a little of the surface soil, and replace it with the richest you can obtain.

The Vines will show as well in smallish pots as in large ones, but unless you attend to them well in watering, they will not swell so well. Unless you had a particular reason for growing the Vines on the bare stage, we would either set them upon earth, or half plunge them into other pots supplied with soil, and thus you would lessen labour, and render the Vines more independent of any omission on your part. Of course, such Vines with roots in the second pots likewise must not be shown as Vines in pots.

You would gain nothing now by planting your Vines out of doors before March or April. If you had a house at work, you may start them inside, and plant out in May, and thus gain time.]

LARGE PRODUCE OF POTATOES.—From a piece of old garden gravelly soil $3\frac{1}{2}$ rods (or 64 yards square), the yield of Potatoes

planted in rows 3 feet apart was (from 56 lbs.) 1025 lbs., all good size 4 sound Potatoes, and very few diseased.—LITTON, near *Sturtebary*.

THE GARDENS AND CONSERVATORIES AT DANGSTEIN.

AMID the beautiful and romantic scenery of western Sussex lies Dangstein, the residence of Reginald Henry Nevill, Esq., and Lady Dorothy Nevill. The mansion, a noble specimen of Grecian architecture, is situated on an eminence near the boundary of a small but well-wooded demesne, and from it may be obtained extensive and picturesque views of that justly celebrated range of hills known as "The South Downs." To the east and south-east the eye wanders over a wide and extensive district of undulating land in the direction of Midhurst and Petworth, interspersed here and there with rich woodland scenery, the view in that direction being terminated by "The Downs," in the vicinity of Brighton and Worthing. Following the chain of hills westward, we notice Charlton Forest and Dunton, near which an observatory, on the estate of the Bishop of Oxford, at Lavington, forms a pleasing object in the distant landscape.

We next notice "The Downs" in the neighbourhood of Goodwood, the seat of his Grace the Duke of Richmond, while more immediately in front the hills rise in proud grandeur, forming, as it were, part of a vast amphitheatre; the view being terminated in the extreme west by the Hampshire hills in the neighbourhood of Petersfield, from which place Dangstein is situated about five miles.

From the summit of the mansion the view is indeed grand, embracing as it does the Hampshire hills to the west, while to the north those of Surrey are faintly visible in the distance; eastward, and almost, as it were, immediately beneath us, stretches that fertile valley known as the "The Weald of Sussex."

This portion of the country which at some remote period was doubtless a vast forest, commences near the borders of Hampshire in that beautiful and romantic glen called Harting Comb, and terminates at the east of the county near Hastings. This lovely valley (till lately a waste, but now enclosed), is a spot worthy alike of poet or painter's praise. It is often spoken of by the renowned Gilbert White in his "Natural History of Selbourne," and contains many rare plants of great interest to the botanist.

The view to the south and south-east extends over a vast area of the fair county of Sussex; and where now stands the peaceful mansion of one of the descendants of the mighty Warwick, would in olden times have been a fitting spot for one of the feudal castles of that renowned baron.

But as it is our intention in the present instance to notice, however imperfectly, the gardens and conservatories at Dangstein, we will leave for awhile the mansion and the delightful scenery by which it is surrounded, and at once proceed to them. Taking our route by a broad terrace walk leading eastward from the mansion, through a portion of the pleasure grounds on our way to the old kitchen garden. This portion of the kitchen gardens, which is about one acre in extent, is bounded on the north by a range of vineries, Peach-houses, and an East Indian Orchard-house, the whole forming a frontage 200 feet in length. A fig-case 87 feet long occupies a portion of the east wall of the garden. The walls are well filled with healthy fruit trees, and the quarters or divisions of the garden are occupied principally by the choicest sorts of vegetables.

On entering the red-hot-house, which is filled for the most part with East Indian epiphytes, the lover of the rare and gorgeous flora of the east will pause to admire the beautiful and curious productions of Nature here collected together. Amongst other rare and valuable specimens of this charming tribe of plants we noticed fine examples of *Vanda suavis* and *tricolor*, from 3 feet to 4 feet in height, and loaded with flower, *Vanda suavis* being unusually fine. *Saccolabium retusum*, *praemorsum*, *Blumei*, and *guttatum*.—*Ediea Larperuta*, with six spikes of flower; *Fiddlingii*, or fox's-brush, the spikes of which were nearly 3 feet in length; *odoratum majus*, and *Brookii*, in fine flower. The rare and curiously beautiful *Cypripedium candidum roseum*, and *hirsutissimum*, both finely in flower. A noble specimen of *Coloche cristata*, measuring more than 4 feet round, and showing an abundance of bloom; and an equally fine one of the rare and beautiful white-flowering *Cymbidium elburneum*.

We also noticed fine specimens of *Vanda curvula Batemanii* and *gigantea* (the latter very rare); *Anguicum caudatum*, *elur-nicum*, and *viridescens*, in robust health; *Dendrobium Dalhousianum*, *Farmeri*, and others; *Lochia superbiens* and *purpurata*; a splendid specimen of a beautiful and rare *Cattleya Acandiae*, with three fine flowers; *Cattleya crispata*, *lobata*, and *Pinelii*, *Sarcopodium Lobbianum*, *Uropedium Lindeni*, and others equally beautiful, but too numerous to mention. Hoys and other climbing plants are trained to the roof. The back wall is covered with a fine plant of *Vanilla lutescens*, which has lately, through great skill and perseverance on the part of the cultivator, ripened several fine pods of fruit. We must not fail to add, that the whole are in a high state of perfection, and reflect great credit on their manager.

We next enter a vinery well stocked with healthy young Vines, the fruit of which at the period of our visit (early in May), was on the point of colouring. The sorts grown being Black Hamburg, Frontignan, Dutch Sweetwater, and Chasselas Musqué. Figs are trained to the back wall of this house; and being planted in a well-prepared border they appear to be thriving admirably, although it is a well-known fact, that this fruit always attains a greater perfection when grown in a house expressly devoted to its culture. The next house we enter is filled with Black Hamburg Grapes, of which there was an abundant crop; the foliage was in a fine healthy condition—a great desideratum in successful Vine-growing. Figs are cultivated in pots placed on a border in the centre of the house, the front benches being occupied with Dwarf Kidney Beans in pots. In the whole of the three vineries the shelves are well filled with Strawberries in a fine fruiting condition; the sorts grown being Keen's Seedling, Black Prince, and Ingram's Prince of Wales. Passing through the late vinery we reach the Peach-house, a commodious structure 28 feet long by 13 feet wide. Here the trees are in a healthy condition and well stocked with fruit. At the extremity of this house is a Peach-case 60 feet in length. The trees are trained to the wall, and the lights so constructed that they can be removed at pleasure. They afford admirable protection from the spring frosts, and serve materially to assist in ripening the wood in autumn—two very desirable objects in this changeable climate. At the back of the range of hot-houses we have just passed through are the various sheds and storerooms—necessary appendages to a first-rate horticultural establishment.

Immediately facing these is a range of low span-roofed houses 102 feet in length, divided into four compartments. The first we enter is devoted to the culture of the commoner sorts of stove-flowering plants, consisting of *Gardenias*, *Ixoras*, *Begonias*, *Rondeletias*, *Dipladenias*, &c. After bestowing a glance on these we enter what is called "the tank-house." Here are cultivated many of the rare and curious productions of tropical and semi-tropical climes.

Amongst others, new and rare, we noticed *Polioth argyrea* trained to a wire trellis, the central portion of which was filled with rough pieces of peat and sphagnum moss, in which the plant had rooted freely—its beautifully variegated leaves may be almost said to vie in splendour with those gems of "the vegetable creation" the genus *Anacostichilus*, *Spharostema marmorata*, and *Allocazia metallica*, both new and rare plants, the foliage of the former being of a bright silvery hue; a good specimen of the new and rare *Cissus porphyrophyllus*—this beautiful plant will certainly prove a very fitting companion for the *Spharostema*, both of which are valuable additions to our stove climbing plants. We also noticed *Plocostemon lasianthum*, the flowers of which somewhat resemble the Hoysas. Here, also, were fine specimens of *Gleichenia flabellata*, *microphylla*, and *dichotoma*; *Pleopeltis nigrescens*; *Neopteris nidus* (the Bird's-nest Fern); *Marattia laxa*; *Oleria carvina*, and the delicately beautiful *Gleichenia hecistophylla*, and other plants equally interesting and beautiful. We must not, however, forget to notice *Tacca integrifolia*, the curiously-formed flowers of which resemble a bat with its wings extended.

A tank occupies a portion of this division, in which are grown *Nymphaeas*, *Nelumbiums*, and other aquatics. Around the sides of this tank is a choice collection of *Lycopods*, and *Selaginellas*, the delicate fronds of many drooping gracefully to the water's edge. Nearly all the varieties in cultivation are here collected together, including *Lysallii*, *atro-viridis*, *Wallichii*, *Lobbi*, *rubricaulis*, *caulescens*, and others; the rare *Lycopodium laterale* from New Zealand, *L. phlegmaria*, and a new species from Borneo, introduced by Messrs. Low & Son, of the Clifton Nurseries, London.

Connected with the large tank is a smaller one, in which is grown the rare and curious Lace or Lattice Plant of Madagascar (*Ovarandra fenestratis*), the beautiful net-like leaves of which float gracefully near the surface of the water. This is a plant which is said to have baffled the skill of many first-rate cultivators of plants, but the treatment it receives at Dungeness appears to answer admirably. As we before observed, it is grown in a small tank connected with, and supplied from the larger one; a waste-pipe carries off the superabundant water, by which means a continual circulation is obtained; the water is kept as nearly as possible at a temperature of from 75° to 80°. To all lovers of the curious and beautiful this plant must ever afford delight. Its introduction into this country is due to the perseverance and enthusiasm of the Rev. W. Ellis, a gentleman who has gained a worldwide celebrity for his researches and description of the natural history of Madagascar.

Immediately over these tanks are grown different species of Sarracenias placed on inverted pots close to the surface of the water. The collection consists of the following varieties:—*Drummondii*, *flava*, *purpurea*, *rubra*, and *variolaris*. They are all in an unusually fine condition, the leaves or pitchers of *S. Drummondii* and *flava* measuring more than 2 feet in length. We fear that justice is seldom done to these curious productions of Nature, but a personal inspection of those we saw at Dungeness would go far to prove what really beautiful objects they are when a proper amount of attention is paid to their cultivation. Here, also, are the beautiful little *Cephalotus follicularis* (the Australian Pitcher Plant), *Drosera dichotoma*, *Nepenthes phyllanthiflora*, *levis*, and others.

The next division of this house is filled with *Begonias* and *Caladiums*, plants alike remarkable for the great beauty and diversity of their foliage. Of the former there is a good collection, whilst the latter contains most of the sorts in cultivation, including *C. argyrites*, *argyropilum*, *Brougniartii*, *Chantini*, *Houlletii*, *Wiglitii*, *Neumannii*, and others. Amongst these are introduced some of the finer sorts of *Marantas*, including *fasciata*, *regalis*, *rosea lineata*, and *Warezewiczii*. A fine plant of *Strophantem floribunda* was trained to the roof and showing an abundance of flower. The fourth and last division is occupied with some of the more choice and delicate sorts of Ferns, a portion being devoted to *Cesareas*, *Gloxinias*, &c. Amongst the different sorts of Ferns are good specimens of *Pteris tricolor* and *argyrea*, *Cheilanthes*, *Nothochloenas*, *Gymnogrammas*, &c., in great variety, and all in excellent health. Also, *Adiantum cristatum*, *Lindsaea Lowii*, and a beautiful specimen of the Silver Tree Fern of New Zealand (*Cyathea dealbata*). A small case occupies a portion of one of the sides of this division, in which were nice young specimens of *Eriosema marmorata*, *Campylobotrys argyrea*, and others. Leaving these houses and the beautiful and interesting objects they contain, we pass on to "the orchard-house," and tropical fruit-house, the two forming a frontage of 130 feet.

In the former, which is a lean-to structure 90 feet long by 12 feet wide, are well-trained trees of Peaches, Apricots, Plums, Nectarines, and Cherries, the whole, with the exception of the Peaches, well stocked with fruit. The trees are planted out in well-prepared borders, that system of culture being preferred to growth in pots. They certainly appear to thrive admirably, and we were informed that they annually produce good crops of fruit. Vines are trained to the roof, and from their present healthy appearance bid fair to produce a plentiful supply of fruit in the autumn. Leaving these we enter the tropical fruit-house, a span-roofed building 40 feet long, 24 feet wide, the height of the centre being about 12 feet. This house was erected expressly for the cultivation of some of the most esteemed fruits of tropical climes. It contains fine plants of Alphonso Mango, and *Mangifera indica* (Mango trees), the far-famed *Mangosteen*, *Garcinia Mangostana*, *Bhignia sapida*, the *Wampee* Tree of China (*Cookia punctata*), *Myristica sebifera* and *moschata* (Nutmeg trees), *Musa Cavendishi*, and *Castiglioni*, *Psidium Cattleyanum* and *priferum* (red and yellow Guavas) loaded with fruit; *Eugenia Jambos* (the Rose Apple), in fine fruit; the *Allspice* (*Pimento vulgaris*), and many others. Here, also, are fine specimens of the much-esteemed Mandarin Orange. To the roof are trained different varieties of fruiting *Passifloras*, *P. edulis* producing a fine crop of fruit. At the west end of this house is a tank, over which are suspended some choice sorts of Ferns, including a remarkably fine specimen of the rare and curious Stag-horn Fern (*Platyceium grande*), *P. stemmianum* and *alcicornis*, *Hymenodium crinitum*, and the rare and beau-

tiful *Drynaria quercifolia*. In this house the plants are placed in sunken beds, hot-water pipes being conducted under the surface of the gravel on which the plants are placed.

Leaving this house we pass on through another portion of the gardens on our way to the Palm-house. This is a noble structure 80 feet long by 50 feet wide, the central portion being 30 feet in height. It is divided into four compartments, including the central division, with three wings attached. We enter at the west wing of the building, which is that portion devoted to the culture of some of the finer sorts of stove-flowering plants. Here are good specimens of *Ixoras*, *Allamandas*, *Crotalarias*, *Chlorantlus inaequalis*, *Euphorbias*, *Heliconias*, *Centradendras*, and others, in fine flower; a noble specimen of the beautiful *Hexacentris mysorensis*, trained to a large globe trellis; a fine specimen of *Friscaea latifolia*, and others. Trained to the end wall is a fine plant of the *Renanthera coccinea* showing flower. Creepers are trained to the roof. Amongst others of great beauty we noticed the pale blue-flowering *Thunbergia Harrisii*, or *laurifolia*, and the curiously-flowering *Aristolochia gigas*, and *Homodoria mixta*, the former stated to be becoming very rare in the country.—W. G. P. G.

(To be continued.)

PLANTS SLIGHTLY FROSTED.

On the morning of the 16th inst. we got up and looked out upon a frost 12° below freezing, the thermometer standing at 20°, and not a single fire had we put on the night before! We were not long in dressing, nor in getting to the fires. Had them all put on, then made a tour of inspection of the various houses: first the greenhouse conservatory. In the coldest end *Primulas* looking most discoloured and covered over with white rime, leaves all stiff. Some *Camellias* white over. A pot of *Mignonne* the same. *Chrysanthemums*, the crimson bloom all powdered with rime. Next house: Firstinery all right, greater body of air and a fire on the day before. Secondinery, not so right. Some bedding *Geraniums* near the glass, leaves all stiff, and powdered with rime. A north house, a sort of omnium gatherum of old *Geraniums* and the forcing stuff, all stiff with frost.

Well, here was a pretty mess. Instead of getting into a stew about it, and bruising the frosty leaves by covering up, we just fell back upon our usual method of getting the fires as brisk as possible, and raising the temperature, whilst the glass is covered by frost; considering the frost covering to be as effectual, if not much more so, than an extra mat covering when the sun has melted and cleared the glass. I am not going to be so foolish as to explain the reason of all this, but the fact is indisputable, for we have not an injured leaf.—N. H. P., Nottinghamshire.

THE OSAGE ORANGE.

This tree, or rather shrub, has long ceased to be regarded as of any worth as a fruit-bearing tree, and the only place I have ever seen it turned to a useful account is Fairlawn, a gentleman's seat in the west part of Kent, where it was planted out in considerable quantities as a hedge plant; and although it had hardly arrived at a size sufficient to stand as a fence against cattle when I saw it, without a little protection on the field side, its robust appearance and quick growth indicated that it would shortly take that position. The spirited owner, Mr. Ridgway, being sanguine that it would make a firm, useful, good hedge. And as a plant its shining green foliage looks well in summer, and being armed with thorns is better adapted to resist the nibbling attacks of cattle than most other plants, and a few years ago a neighbouring nurseryman offered it at a reasonable price for hedge purposes; but I have not seen it in use as such anywhere but at Fairlawn, where, also, many other experiments were being made with shrubs and trees generally esteemed tender. Indian *Azaleas* being planted out by scores, and were doing remarkably well, as were also some of the more choice kinds of *Rhododendrons*, and the most recently-introduced *Conifers*, but I never heard of the Osage Orange blooming there. Most likely when it does so it will be at the tips of the shoots of the preceding year, and then rarely ripen, and are cut back by the frost. Against a wall, however, in dry situations, it is not unkindly but it may have bloomed. If so, perhaps some one will be kind enough to describe it through the pages of THE JOURNAL OF HORTICULTURE.—J. ROBSON.

THE BOTANICAL FEATURES OF THE SIDES OF LOCH NESS.

By GEORGE ANDERSON, Esq., Inverness.

"The Oak, the Ash, and the bonny Ivy tree,
Ah, they flourish best in the north countrie."—OLD SONG.

Or botany it has been justly said, that "the spleen is seldom felt where Flora reigns;" and although I cannot expect to add any inducements to its study, yet I will crave the indulgence of my readers while I offer a few observations, made several years ago, giving some faint idea of a district as richly decked with Nature's bonities as any in the British Isles.

We have been accustomed to think of the Highlands as the land of storms, of darkness, and of desolation; and when we have beheld the huge mountains rising in our way and crossing our path, as if forbidding approach to the retired habitations within their bosoms, we can scarcely believe that the rich descriptions of vegetable life, on the rocky bounds of Loch Katrine, so powerfully given by the bard of our times, can extend to the north of that celebrated inlet. Neither will our prepossessions, if taken from Dr. Johnson, be at all calculated to remove that dread of vegetable death, which the first sight of the cold Celtic hills is apt to impress on the traveller who journeys from the south. It is not to be denied that the character

of our Caledonian mountains is, in general, that of bleakness and sterility, and it is rather to be wondered at, how, with this prevailing barrenness, spots should be found, and sunny braes and winding valleys should present themselves, clothed with the most enlivening and luxurious vegetation. As men, I believe we can easily understand why, to the lonely shepherd,

"Dear must his cot be to which his soul conforms,
And dear the hill that lifts him to the storms;"

but as naturalists, admitting the increased warmth of the sun's rays in deep sequestered glens, and fine-lying hillocks, it is still not so easy to account for the vast multiplicity of forms, and the beauty and closeness of the "bonny, wee, crimson-tipped flowers" that everywhere bedeck their surface.

Though torn by wintry rains, and stunted by early snows, I believe every one who has wandered among them, and contemplated the sweet scented flowers of the wild Thyme and the waving Heather in its bloom, or followed with the enthusiasm that I have done, the haunts of the dun deer and the roe, will

LOCH NESS, FROM THE BLACK ROCK.

be tempted to apply to them, with but a small change of words, the expressions of the eastern poet—

"Our rocks are rough, but stings the
The Avern waves her yellow hair,
Lonely and sweet, nor loved the less
For blooming in a wilderness.

"Our sands are bare, but down their side
The silver-froth is catching
As gracefully and gaily springs,
As e'er the marble courts of kings."

But I believe the variety and beauty of our alpine and lea plants are well known and generally acknowledged. I am not aware, however, if the number and copiousness of the forest trees and brushwood plants, to be met with on an extensive survey of the Highlands, have been properly ascertained and noticed, or whether it is generally known that many of those larger trees, which are thought almost peculiar to more southern

counties, have been frequently found of tolerable size in many parts of the districts I allude to.

I must offer a general and short description of the face of the country. It is one of the very peculiar features of this part of the island that, similar to the extensive valley which cuts across our southern division, from the Firth of Forth to that of the Clyde, there is in the north an equally extensive one, less elevated, but more abundant in water, which connects, by its lakes and by the Caledonian Canal, the Atlantic Ocean with the German Sea, and which is well known under the name of the Great Glen of Scotland. Two-and-twenty miles of this natural opening are occupied by the deep waters of Loch Ness, and if the mountains which surround its margin are not so picturesque, towering, and rugged, as those of the west coast, they are still more varied in inclination and outline, more protected from the rage of the Atlantic storms, more exposed to the sun, and, therefore, more favourable to vegetation.

Three or four lateral valleys, all of them differing in botanical characters, according as they are wide or narrow, and transverse. I wave with the stately foliage of the purple Foxglove; the interlocking spaces of green sward are filled with twining branches of the white and red Dog Rose, in contrast with the yellow

by a smooth-flowing stream or a foaming torrent, open them selves to the lake, and discharge their moisture into its collected waters. One of these, called the Glen of Urquhart, is exceedingly beautiful, and much admired from the climbing woods of Birch and Fir which adorn its sides, screening it from the wintry blast, and from the broad fields of highly cultivated land which occupy its lower declivities. It expands at its junction with the lake, into a wide bay, one of whose promontories rises gently in rounded terraces of green coppice and corn land—where formerly stood one of the early wooden churches of the seventh century, built according to the Brevicium Aberdonense, of heven Oak, and dedicated to St. Moarbrutha. The other promontory is crowned with the venerable walls of the Castle of Urquhart, once the seat of the proud Cumyns, Earls of Badenoch, and the last castle which stood out against the usurping arms of Edward I. In case I should forget afterwards, I may remark, in passing, that here, "where ruin greenly dwells," are found some elegant specimens of the beautiful plant *Geranium lucidum*.

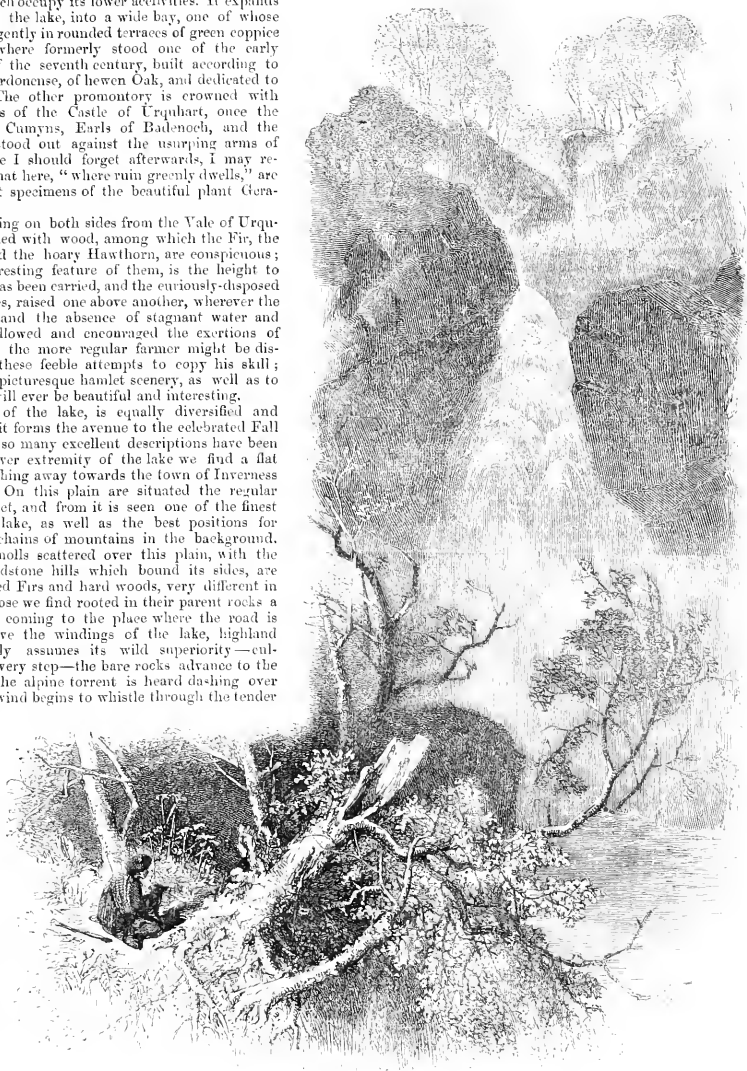

The hills, stretching on both sides from the Vale of Urquhart, are well clothed with wood, among which the Fir, the Weeping Birch, and the hoary Hawthorn, are conspicuous; but the most interesting feature of them, is the height to which cultivation has been carried, and the curiously-disposed patches and terraces, raised one above another, wherever the slope of the hill, and the absence of stagnant water and brushwood, have allowed and encouraged the exertions of industry. Perhaps the more regular farmer might be disposed to smile at these feeble attempts to copy his skill; but to the lover of picturesque hamlet scenery, as well as to the botanist, they will ever be beautiful and interesting.

The south side of the lake, is equally diversified and romantic; indeed, it forms the avenue to the celebrated Fall of Foyers, of which so many excellent descriptions have been written. At the lower extremity of the lake we find a flat alluvial plain, stretching away towards the town of Inverness and Fort George. On this plain are situated the regular farms of the district, and from it is seen one of the finest approaches to the lake, as well as the best positions for viewing the grand chains of mountains in the background. The low waving knolls scattered over this plain, with the smooth-flowing sandstone hills which bound its sides, are covered with planted Firs and hard woods, very different in appearance from those we find rooted in their parent rocks a little way on. On coming to the place where the road is first made to observe the windings of the lake, highland scenery immediately assumes its wild superiority—cultivation recedes at every step—the bare rocks advance to the edge of the road—the alpine torrent is heard dashing over their surface—the wind begins to whistle through the tender branches of the Birch—and the lake, dashing its waves at our feet, all powerfully convince us that we are now fairly in the land of the "mountain and flood."

The road, cut in many places, especially on the north side, out of the solid rocks, winds along their jutting foreheads, overhung with the drooping boughs of the Birch, or shaded by the spreading arms and trunks of the wild Ash, the Oak, and the Hawthorn. The declivities of the hills above us are covered with thick woods of

the same trees, intermingled with the Hazel; the abrupt crags

Honeysuckle. Here, then, the botanist should begin his researches.—(*Gardener's Magazine of Botany.*)

LOCH NESS.

the same trees, intermingled with the Hazel; the abrupt crags

VINE ROOTS PROTRUDING FROM THE POTS.

I HAVE a dozen Black Hamburgh Vines in pots, three years old. When I purchased them in the autumn I placed them on some loose dung, and I find that the roots have grown through the pots into the dung. When I want to move them into the forcing-house, what had I better do with the roots that have come through?—VASTUS.

[If you propose putting the pots into a bed of fermenting material, or on a bed of earth, you had better lift the roots and plant them again. If you propose placing the pots on a shelf or stage, you could place the pots inside of a saucer, or even of a larger pot, and that being filled also with earth, you would minimise the trouble in attending to them. If you propose growing the Vines in these pots, and exhibiting them as Vines in pots, then you must cut these roots away and prevent any growing afterwards. There will be plenty of roots in the pots.]

TRAINING ON WALLS BY NAILS, AND SHREDS, AND OTHER MODES.

THE whole question, in answer to Mr. Starkie Baldwin, resolves itself into one of circumstance. In old walls that can hardly be made worse, the old custom of nailing may still be resorted to. Circumstances compel us to resort to this old-fashioned mode, but we use as few shreds as possible, as we do not think that either walls or trees are improved in appearance by being made to resemble a rag shop. Whenever a wall is fresh faced, fresh pointed, or a good new wall provided, we should decidedly in every case, either wire or stud. For Apples, Pears, and Cherries, the wires may be strained two bricks apart, and 2 inches from the wall. All the larger shoots we would fasten with rope-yarn. In nailing in the common way, we would use rope-yarn or willows, using thread in the one case, and small shreds in the other for points. For Apricots and Peaches, we would have the wire strained to studs only 1 inch from the wall. This would afford plenty of room for the tying, and yet permit of no great draught of air between the trees and the walls—in fact, the leaves at this distance, and the wood too, will receive a good amount of heat from the wall, and there will be no holes in the walls for harbouring woodlice and numberless other insects and their eggs. This plan we believe would in a few years be cheaper than nailing, and, ere long, we may so cultivate many trees, that there will not be so much pruning and laying-in, and fresh tying or nailing every winter. It is quite practicable even with Peaches and Morello Cherries, to do nearly all the pruning and tying in summer, and then future gardeners may escape the rheumatism and other pains to which most of us are subjected before we hardly pass middle age. This wiring is used greatly for conservatory walls, and it will be equally efficacious for fruit trees; but the tenderer the trees are, the nearer should the wires be to the wall, so that the string may just be slipped through and over it. If this is not attended to, Peaches, &c., will not ripen their wood sufficiently in cold places.

We have no objection to Cuba bast, except the expense. We object even to matting on the same score, only when much is done, and workmen are careless, a little waste with them is not so expensive as waste in thread would be. Common string or small tar cord for the biggest branches, and fine string for the smaller twigs, tied loosely so that the branches hang in the tie, is the neatest and most economical of all, if the workman manages the tie-end so as not to lose a bit by cutting off close to the knot. There is not one young gardener in a hundred but will waste no end, even of matting or Cuba, if not looked after. You will find as many inch, and two-inch, and three-inch pieces lying at the bottom of the trees, as, put together, would have done all the tying. This can only be avoided by using as much of the end of the string as will make the knot and no more. Half an inch cut off is just so much wasted, whatever the tying material may be. If matting or Cuba is used, the strings if twisted should be twisted only once, if the ends are held as they ought to be, that will do. How often will a man twist a string of matting, make one tie, cut off 2 inches or 3 inches, and then stop to twist again? Well, a nice little thread avoids all this, and where much is to be done the small ball of thread may roll in the workman's pocket. Such cord and thread I believe to be the cheapest sources under such circumstances.

Where walls are good and there is a desire to keep them so, but

wiring is thought to keep the trees too far from the wall, the wall is studded with nails, designed to be permanent, and the trees are tied to the nails. The distance of these nails may be regulated according to the tree cultivated. Placed in lines some 5 inches or 6 inches apart is a good distance. The largest cast metal, or others fully as large, should be used. If such is resolved on, it is a good plan to heat the nails pretty well in an old saucepan, and then pour them into a vessel of oil, allow them to remain for an hour, and then drain the oil from them by a sieve. Thus done they will not rust for many years—a matter of importance if the wall is to be kept nice and in good order. Iron studs a little larger than nails, with open holes at the ends would be more handy but more expensive.

Where the old mode is resorted to, we would still prefer rope-yarn, tar string, or willows for the big branches, and shreds only for the smaller twigs, and these as small and dull coloured as possible. The pack-thread willow is the best, and when small ones in quantity cannot be obtained, from the willows growing too strong for that purpose, a part of the shoots may be topped in spring, which will cause two or three shoots to come instead of one. In tying, the willow is first twisted round the nail, then brought round the shoots, and twisted with a running knot, the strain keeps it fast enough. Men used to it will do the work as quickly as with rope-yarn or more so.—R. FISHER.

MUSHROOM CULTURE.

YOUR correspondent, "AGRICULTURIST'S," method of growing Mushrooms in boxes, is a plan that suits me exactly. Consequent on my beds being every winter torn up by mice, I am having two boxes made, and fancy I can have them covered with a wooden-lid without injury to the crop, but cannot have horse-droppings from gatherers to prevent too rapid fermentation. Do you think a mixture of cowdung will have the same effect as a substitute?—ALPHA.

[At this season it will be better to employ horse-droppings from the stable without any mixture of cowdung, as it would, probably, check fermentation too much. There is no necessity for horse-droppings from the road unless very convenient, those from the stable when unmixt only require a little more time to reduce the violent heat. Cowdung has not been tried, and, therefore, cannot be recommended. Small-meshed wire coverings for the boxes would be better than wood, admitting some air and light, and, probably, the Mushrooms would be of a higher flavour.]

A PEAR TREE PARTLY ENCLOSED IN AN ORCHARD-HOUSE.—SECOND CROP OF FIGS.

IF, in forming a lean-to orchard-house, a Winter Nalis Pear (with an eastern aspect) of ten years' standing be partially included with its stem, should the enclosed branches be encouraged?

Should a second crop of Figs (three parts formed) be allowed to remain on the tree, which latter is placed in a house provided with boiler and water-pipes, but only heated to keep off the effects of frost from plants and flowers?—A SUBSCRIBER, *Bristol*.

[If the Winter Nalis is well supplied with fruit-buds it will be encouraged to set well; but unless you can give plenty of air the flavour of the fruit will not be so good as if more exposed.]

Did you give more heat to your Figs they would not ripen for six weeks, and then be flavourless. With the heat you speak of they will most likely drop ere long. Better take them off at once. Cut them, do not pull them. If any about the size of Peas, let these remain.]

FAIRRIE'S QUEEN PINE APPLE.

IN your Journal of October 29th I see that Mr. Appleby, in writing on the "Culture of the Pine Apple," in describing the varieties, stated "Fairrie's Queen, I first saw this fine variety at A. Fairrie's, Esq., Aigharth, near Liverpool, in whose piery it fruited, I believe, for the first time in England." Now, I am anxious to know on what authority this Pine has obtained the name of Fairrie's Queen.

The Pine in question was raised at Hurst House, near Liverpool, by Mr. Durden, the gardener at that place, and the stock purchased by Mr. Fairrie for a good round sum.

It has been before the public under the name of "Hurst House Seedling," and is sold as such.

It is a particularly dwarf variety, of good flavour in summer, but nothing in winter. Many who have purchased it complain of its being slow to fruit; but, as I saw plenty of fruit at Aigburth, there may be some peculiarity of treatment required.

The giving new names to plants already named and known may be of use to nurserymen and those interested in their sale; but the reverse to gardeners and purchasers. It was this alone caused me to notice the subject, as Mr. Appleby's Fairrie's Queen Fine Apple is the Hurst House Seedling.—T. SHORTT, *Raby Castle*.

VENTILATING A VINERY — WATERING — PROPAGATING BRUSSELS SPROUTS.

WHAT do you consider the most efficient and at the same time economical way of ventilating a span-roofed vinery, 27 feet by 14 feet, which, being enclosed on every side by seven-foot-wide lean-to's from the eaves, must have air given in the roof?

The mode recommended by you of swinging every alternate pane seems fraught with considerable difficulty and expense; and moreover, the uppermost pane of glass by the roof-tree is not 20 inches by 15 inches deep as the rest of the roof, but only 20 inches by 10 inches deep, occasionally two slips of 5 inches (so glazed for economy's sake to avoid waste). Under these circumstances, after conference with my glazier and joiner, I cannot but think some other plan might answer as well or better.

One plan would be to have sash-frames made 6½, or 4½ inches by 25 inches, to be glazed with the two panes at the apex, and hinged to the roof-tree, and shut and opened by a flat iron bar pierced with holes fitting on a stud in one of the sash-bars, or in a piece of wood fixed across and between the sash-bars to receive the frame. If this seems to you a likely plan, please advise me as to the length—three sash-bars or two, and as to the number which would suffice. I only suggest this plan, because it seems to me likely to be cheaper than pivoting a square here and there, and because I cannot see how to turn the water by that method, though I have tried my best to understand Mr. Fish's directions, Vol. XXIII, page 347.

Another plan that has occurred to me is to make some of the large panes at the eaves, or any other part of the roof, slide by fastening a slip of wood under them along the sash-bar, and surrounding the square with tin, to the centre of which a string or wire might be attached and pass through an eye, so that one might pull the pane up easily. This seems to me likely to be the cheapest plan as far as first cost goes, and also the simplest if it will work. As I have not the advantage of experienced neighbours or workmen, I should be exceedingly obliged if you would kindly give me your advice when convenient.

Two years' experience in orchard-house culture has given me a suggestion which, for all I know, may be nothing new, but at all events I feel myself bound to give it. Instead of a syringe, I find that a small forcing-pump (fixed or moveable), inserted in a tank for collecting the roof water, with India-rubber hose the whole length of the house, not only saves labour but enables the syringe to deluge every leaf with the utmost ease and certainty. Of course, two are required—one to pump, another to direct the hose. Where the work is done by gardeners I think this simple plan cannot be surpassed, and saves much time and labour both in syringing and in watering pots. I must, however, warn my brother amateurs that the hose is very detrimental to good clothes, and I would therefore recommend such to obtain an apparatus to be worked by one alone. What I would recommend and mean to adopt is a garden engine on a scale small enough to go among the fruit trees without danger, with a hose of about 4 feet attached to it, so that the operator can pump with one hand and direct the stream with the other. Such a machine could be made by a plumber or tinsmith for about 25s., and would save many an arm-ache and red spider too.

Before concluding, may I ask why gardeners habitually sow Brussels Sprouts, when the plant will shoot again from one of the bottom buds if properly managed, and produce its heads as soon as sown plants—a fact I learnt by one or two stalks having been left in a corner of my garden this year?—IGNORAMUS.

[In answer to your letter, Mr. Fish says that you would need, at least according to your plan, four ventilators, 4½ inches

by 25 inches, and that he has no objection whatever to any of the plans you propose for ventilating, provided sufficient air is given; and he also thinks, that if you cannot open in the lean-to's at the side, as many squares ought to be made to open in the eaves of the central house. He does not, however, think that either plan will be so simple as one he detailed lately for giving air to a lean-to house at the apex of the roof, and which is even simpler than that described at page 347, Vol. XXIII, inasmuch as a stout screw nail does all the work of the pivot. Suppose, then, that every alternate space is ventilated; and as 10 inches would not be enough, that these ventilators were 20 by 25, or rather 20 by 23 in the opening, for on taking out the ten and fifteen-inch squares, a piece of wood 2 inches broad at least would have to be inserted to receive the upper end of the squares and for the bottom of the ventilator to rest upon and just pass over to throw the water down the glass. The space between the rebates will therefore be 20 inches by 25 inches deep. The bulk of the ventilator will therefore be 20 inches wide. The upper third will be about 18½ inches, so as to go freely between the rafters. The top and sides may be 2 inches wide and 2 inches deep, grooved to receive the glass. The bottom rail should, like the front rail of a common sash, be 2 inches wide and 1 inch thick, and the glass will rest upon that. The lower part of the ventilator will therefore rest on the cross-piece placed to receive the third pane from the top, and will go between the rebates and rest on the rafter at the sides. The upper part of the ventilator will go between the rafters, and be fastened to them with two screws firm in the rafters but loose in the ventilators, so as to move easily as on pivots. A string fastened to a hook or ring in the centre of the top pulls the upper part of the ventilator downwards, and causes the lower part to rise upwards, and thus the air is given at the very apex as well as further down, and the stream of air is divided. These strings or stout pieces of wire may be fixed to a rod, and all the ventilators moved at once if deemed advisable. Whenever the strain is taken off the string the ventilators will shut of themselves by the weight of the lower part, only they should not be allowed to come down with a crash. A pin to fasten the string to is all that is needed. Where great nicety is required a little rain may come in where the ventilator joins the ridge-board. If there is lead there, it could be turned up at the edge, so as to throw the water on the next row of glass where there is no ventilator. If there is no lead, two small fillets of wood placed over the openings, will throw the few drops past in a similar manner. Then for the part of the ventilator that goes inwards, a strip of zinc may be placed on the upper part of the rafters to overhang these upper eight inches of ventilator; and if great nicety were required, a strip of zinc an inch wide might overhang the lower end of the ventilator 16 inches deep that stands above the rebate. Place two strips of wood to represent rafters, make a ventilator on the same principle, and try it before adopting it; but by all means try any other plan you consider better. There is one thing in which your sash hinged at the back and opening outwards will be an improvement—and that is, you can move easily cover the opening to keep out flies, wasps, &c.; and we like air in such circumstances to come in and go out at the highest point. We do not think that in economy of air-giving it would excel.

In a span-roofed house no plan is better than having a double ridge and the openings for air between them. But for the look of the thing, we would advise our correspondent, if he objected to all these modes, to take out his ten inches of glass and have a wooden ventilator of that width all the way, say in three divisions, which could be raised easily by a pulley against the back wall.

As for the pumping and syringing, it is all very well for amateurs: what about the poor gardeners' clothes? Small moveable engines are common enough, and are very useful in many cases, but no twisting and bending of hose will ever get about a plant like the flexible arms of a good workman with a good common syringe. We do not discourage any of these nicknacks—they encourage trade, and amateurs can do the work often in a more cleanly way with them, just as a lady may pick up weeds nicely with a pair of gloves on, though we should consider a garden boy with gloves on for such a purpose not worth his salt, let alone the beef and greens. In most cases, for general purposes the simpler the tools are the better and more efficiently the work will be done. A general brought us one day from one part of the garden to the other extronity, to show us how waterbarrows on a frame and wheels could be greatly improved, and that was by having a brass tap fixed near the bottom so as

to fill the pots from it. Now this plan would suit a lady or a gentleman nicely, and would save fine polished boots from being tarnished; but as the barrel was hung on pivots, and could easily be bent to a side after the first painful or two were dipped out of it, we should expect the barrel to be about emptied whilst the man stood for a pail to be filled from the nice tap. If a natural force can be applied there would be much use in such hose, not only for particular but for general purposes; but in the case supposed we fear it smacks too much of the improvement in waterbarrows.

Gardeners habitually sow Brussels Sprouts, because, on the whole, it is the best plan; not only will the roots grow as you state, but the side shoots will also grow if firmly inserted in the ground; and though many of these will throw bloom, yet, if severally nipped off, a good plant will ultimately be obtained. We have grown quarters of Cabbage in the same way, but we found no benefit in a practical point of view, though it is interesting for keeping a good sort. We have now some strong plants of Scotch Cabbaging Borecole or Kale that have thus been propagated for three years. At first we did it in case we could not get the sorts, stripping off shoots in April, and planting them like young plants, but we do not see that they are any better than young plants, though they certainly save seed, and the botler of slugs eating them when young; but there is a good deal of trouble in getting an even crop, as some side shoots are more liable to throw up flower-stalks than others. We may mention in conclusion that the above Borecole is longer in seeding in spring than any other green we know. These things are nothing strange to gardeners, but we feel sure many amateurs and cottagers will be obliged to our correspondent for directing attention to them. Scarlet Runner roots if saved in sand, like Dahlias, will grow for a number of years; but then they do not do better than seedlings.]

NEW AND RARE PLANTS.

HOYA LACUNOSA var. *PALLIDIFLORA* (Pale-flowered Farrowed Hoya).

Nat. Ord., Asclepiadaceæ. *Lin.*, Pentandria Digynia. This has also been called an *Otostemma*. Flowers greenish-white, and inconspicuous. Native of Java.—(*Botanical Mag.*, t. 5272.)

METISIA DECCURENS (Decurrent-leaved *Metisia*).

Nat. Ord., Composite, *Mutisieæ*. *Lin.*, Synœnesia superflua. It has also been described as *M. heliantha*. A splendid species of this scandent, cirrhose-leaved genus. Messrs. Veitch and Son flowered it in July of the present year. "It endured the last severe winter unharmed in the open air at Exeter, without a shelter. It is a native of the Andes of Chillan. The fruticose plants of the high and dry Andes of Chili, are difficult of cultivation, it is feared, and require very peculiar treatment."—(*Ibid.*, t. 5273.)

SALYIA CACALEIFOLIA (Cacalia-leaved Sage).

Nat. Ord., Labiata. *Lin.*, Diandria Monogynia. Nearly related to *S. patens*. Native of Chiapas, Mexico, growing in Pine forests, and probably hardy. Flowers deep blue.—(*Ibid.*, t. 5274.)

GONATANTHUS SARMENTOSUS (Sarmentose *Gonatanthus*).

Nat. Ord., Aroidæ. *Lin.*, Monœcia Polyandria. Also called *Caladium sarmentosum*. The generic name alludes to the geniculate character of the spathe, and the specific name to its throwing out stolones. Native of the Khasia and Himalaya Mountains. Flowered in the Kew store in May. Spathe tawny yellow, and sometimes a foot long.—(*Ibid.*, t. 5275.)

IMPATIENS FLACIDA (Soft-leaved Balsam).

Nat. Ord., Balsaminæ. *Lin.*, Pentandria Monogynia. It has also had applied the specific names of *pulcherrima*, *latifolia*, and *lucida*. "A lovely species of a lovely genus." Native of Ceylon mountains, at elevations of from 3000 to 6000 feet. Flowers purplish-lilac.—(*Ibid.*, t. 5276.)

SPIRANTHUS CERNUA (Drooping-flowered *Spiranthus*).

Nat. Ord., Orchidæ. *Lin.*, Gynandria Monandria. It has been included in the genera *Ophrys* and *Neottia*, but with the same specific name. It is really a native of Ireland. It was discovered in 1810, near Castletown, opposite to Bear Haven, on the north side of Bantry Bay, Cork, and is still to be found there.—(*Ibid.*, t. 5277.)

SCARING BIRDS FROM GOOSEBERRY BUSHES.

RECENTLY IN THE JOURNAL OF HORTICULTURE I observed that a correspondent complains of the destructive ravages of birds on his Gooseberry bushes, and has hitherto tried a variety of expedients without being successful in putting a stop to their depredations. Here we are terribly annoyed by these feathered imps attacking not only Gooseberries and Black Currants, but also May Duke Cherries. The former, however, they seem to be specially fond of. But all that we have to do, as far as Gooseberries and Black Currants are concerned, is to carry a number of white cotton threads, from point to point, of the young shoots, all over the bush, forming a sort of net work. This at once puts a stop to further mischief. But however efficient this simple remedy may prove, in some instances, it utterly fails in others. In cases of failure with cotton thread, I have used red Berlin wool with good effect; indeed, it is the only preventive I have any real faith in, put on in the same manner as the cotton thread, only with the addition of a few white or light-coloured feathers tied loosely on the cross threads. I have known this succeed in scaring them away when everything else tried had failed.

There is another substance I have made use of, and frequently with good results, powdered hellebore 1 lb., to four gallons of water (cold), well stirred and sprinkled over the bush by means of a dusting-brush. We use it for the destruction of caterpillars, and on one occasion I sprinkled a quantity of it over one or two bushes, and noted the result, when it soon became evident that the hellebore was distasteful, as these bushes in future remained untouched. The worst of this remedy is, that heavy rains wash it off and leave them again exposed.

If your correspondent "D," has not already tried either of the above, it might be worth while to make the experiment.—J. D., Lancashire.

WORK FOR THE WEEK.

KITCHEN GARDEN.

EVERY opportunity of favourable weather should be made available in carrying out whatever digging, trenching, and draining have been marked out for completion during the winter months. *Brussels Sprouts*, when the head is set the dead leaves to be removed, but none of the green ones, as they protect the young side sprouts. The same treatment is applicable to Scotch Kale, and other winter greens. *Cabbage*, when a favourable opportunity occurs take advantage of it to earth up the autumn plantation; it not only invigorates but prevents them from being loosened by the wind. *Carrots*, never neglect giving air to those under hand-glasses and in frames daily, unless during severe frost; if the plants are now drawn by an insufficiency of air they will be liable to button off. *Endive*, any that may have been planted in frames should have air freely admitted, to prevent its rotting. *Mushrooms*, the beds out of doors to have a thick covering of straw, over which to be placed mats, to protect them from wet and frost; when the straw is wet it should be replaced by dry. *Parsley*, as it is indispensable for the kitchen frames should be placed over a portion to protect it from frost, some roots should also be potted, and placed in some house, pit, or frame, where it will be protected from frost, and when wanted to be placed in a house where forcing is going on. *Potatoes*, the land intended for their culture to be rough dug, and exposed to the action of the weather as much as possible; and manure, if employed at all, to be sparingly applied. *Radishes*, as soon as they come up in the frames give air at every favourable opportunity, to prevent drawing. *Strawberries*, if not already done, to be dressed with short rich manure; as it is not advisable to dig between the rows, the manure can remain on the surface until the spring, when it can be slightly pricked in with the fork.

FLOWER GARDEN.

Deciduous shrubs may now be pruned whenever there is time, except during severe frost. Many of the large-growing sorts will require going over to reduce straggling shoots to proper limits, and to thin out where too thick. Prune *Cytisuses*, *Spiræas*, *Deutzias*, and other such low growing shrubs, if a good show of flowers and uniformly-shaped bushes are required. Where walks are in good condition, but have weeds still making their appearance on the surface, recourse should be had to hand.

picking, as the use of the hoe and rake should be avoided at this season of the year as much as possible. The various walks which are overrun with Starwort, Liverwort, and the various Mosses had better be dug over with the spade, thereby consigning the whole to oblivion, and presenting a new surface to the eye, which, when rolled down smooth and level after the operation of digging is finished, will maintain a neat and clean appearance for some months to come. Take advantage of wet days to clean out flower and other seeds from their stalks, and to tie them neatly into packets, correctly naming each sort; also to make and write labels, to prepare sticks, and to tie them into bundles, and to stow them away in a dry place until they are wanted.

FRUIT GARDEN.

Continue to prune and nail wall trees; but in no case should old shreds be used without boiling, as they generally contain innumerable eggs of insects. It is also an excellent plan to wash wall trees with hot water from a garden engine; it should be boiling when put into the engine.

STOVE.

Continue former directions, hardening growths, and endeavouring to promote a quiet atmosphere, rather dry. Keep down all unnatural night heat.

GREENHOUSE AND CONSERVATORY.

Fires will be required here occasionally in dull weather, to be lighted in the morning in order that the houses may be thrown open during the day to promote a free circulation of air. This will dry up damp, and help to keep the plants in a healthy state. As a damp stagnant air is the principal cause of mildew amongst the more delicate kinds of Heaths and other hard-wooded plants, it is advisable to give them as much air as possible at all favourable opportunities. Stir the surface soil of the pots, to remove moss as well as to promote a free evaporation from the surface. Seedling Cinerarias and herbaceous Calceolarias to have a shift if requisite; if the plants are strong they may be transferred at once to their blooming-pots. Particular care is now necessary to keep the conservatory dry; water to be applied carefully in the fore part of the day, and every drip or water on the floor to be mopped up. Everything in the way of decaying blossoms, leaves, &c., should be at once removed; for if such things are allowed to remain they assist in producing mildew, dampness, and decomposition. The winter-flowering Correas, Epacris, Acanth, Polygalas, Pinacolas, &c., will now begin to make a charming addition to the other inmates of the conservatory. Take care to give attention to judicious watering, more especially to the Epacris; it will not do to trust this process to inexperienced or careless hands. The bulbs of various Japan Lilies to be shaken out and repotted in a good fibrous loam with a portion of coarse sharp sand, and a pretty liberal supply of charcoal intermixed, good drainage, and a portion of rubby charcoal to be laid over the drainage, the bulbs just require to be covered, while the pots in the first place should only be two-thirds filled; for, as they put forth abundance of roots for 2 inches or 3 inches up the stem, they may be considerably assisted by earthing up in spring with the same material. Let all bulbs arousing from their dormant state—such as the Amaryllis tribe, the Lachenalia, Oxalis, with others—have very moderate supplies of water until the leaves are somewhat expanded.

FORCING-PIT.

The Hyacinths and Narcissi potted in September or the early part of October may now be examined, and introduced successively in small quantities to this pit when their buds are 2 inches long, to be plunged overhead at the front or darkest part of the pit, covering them 4 inches in the old tan. Shrubs, if in proper condition for forcing, may be introduced immediately—such as Azaleas, Rhododendrons, Roses of sorts, Persian Lilacs, Sweet Briar, &c.

W. KEANE.

DOINGS OF THE LAST WEEK.

ICE-HOUSE.

Frost on the 16th, a fall of snow on the 17th, which saved vegetables much; and a keen frost on the 18th and 19th, followed by a thaw on the 20th have regulated most of our operations. Cold pits shut up and covered on the 16th remained covered until the 20th, with the exception of a few openings here and there. We hardly expected the frost to continue; but

if it should have lasted a week or more we were unwilling to disturb the covering of snow, which Nature had given us as the best of all protection; but when the sun succeeded in melting that, there was no reason why the covering should not be removed. We would have been at the ice-well-filling, but that would have interfered with a shooting party; and, therefore, we must wait for the next chance. In filling the ice-house we have used no straw for years, and it keeps all the better for the want of it. I know from trials, however, that a covering of dry straw on the top, and a circulation of air over it would keep it better still. As it is, our house would generally last two years if we should happen to miss one season. Other people like myself may have had some misty views on this subject; but to Mr. Beaton the lovers of cool luxuries are indebted for a clear definite philosophical statement of the best mode of preserving ice under different circumstances; and it is not the most generous thing in the world, to bring back a portion of his ideas across the Atlantic as some grand new discovery from our Yankee friends. Our late friend Mr. Errington would have said that was "screaming with his whistle."

KITCHEN GARDEN.

The chief thing here was making Celery all snug and safe, which the snow managed very nicely. A nice lot of white-hearted Cabbage we would have whipped into a shed, and set them then at their leisure, but the snow saved us the trouble. Savoys are more forward than usual this season; and, if the weather should again threaten to be severe, we will do the same with them, so that a little litter may be thrown over them. We have found there is little necessity in such circumstances for taking the plant up by the roots; if cut over by the surface of the ground, and the stem inserted in earth, it will absorb enough of moisture to keep the head fresh. The same will apply to Cauliflower and Broccoli when come to fully half their size. Looked after young Parsley in case there should be a continued frost, as Parsley is a herb that must be had every day. Cleared away the rest of the Peas, Scarlet Runners, and laid down Broccoli a little, commencing at the north side of the rows, taking out a spadeful or two of earth—say 6 inches or 9 inches from the plant, pressing the plant down into the sloping opening, and then covering the stems to keep them down with earth removed from the next plants in the rows.

FRUIT GARDEN.

Pruned a little out of doors. Found that the leaves had not dropped from the Apricots, and left them alone in order that the first frost would not be so much felt by the buds. The wind will now sweep them off without our help. Covered up Strawberries that were in pots with hay and straw. Frit trees and Rhododendrons in pots, mulched all over with litter to prevent the frost getting at the roots. Removed the leaves getting yellow from the late viney, so as to keep the house sweet. Gave fire early with plenty of air, when mild, to keep the atmosphere dry. Roof too flat for this season, so that the condensed moisture will drop at times in spite of us. A steep roof is the roof for keeping Grapes late, as the water runs down the glass. Without that the sash-bars ought to be made with grooves below them to catch the condensed water from the glass, as it seldom drops from the glass, but finds its way to the sash-bars. When forcing of any kind begins, the great thing is to start gradually.

ORNAMENTAL GARDENING.

In the stove placed all plants that were showing flower, or that wanted more heat at the warmest end, and kept those intended for spring and summer blooming much cooler and drier; as for these purposes, in many cases, we wish to keep the plants in health, rather than to grow them, and this requires less fuel than if the house was kept at a high temperature. The temperature at the hottest end will average 60°; the coolest end from 50° to 55°, as opportunity offers; the plants needing it will be top-dressed or fresh potted, as there is so much else to do in spring. Many stove plants, as Gardenias, thrive all the better of this cool treatment in winter, and they are less liable to insects than when kept warmer. The same rule applies to *Ixoras* at this season, though they should not be below 55°; a sort of rest at that temperature, and kept rather dry, will cause them to thrive all the better when removed gradually to a sweet growing moist temperature of 70° to 75° in February and March, and at that time both Gardenias and *Ixoras* delight in a little sweet bottom heat, such as sweet tan would give them. Those

who wish to have their conservatories gay at Christmas should now be moving some well-rooted bulbs into a hotbed or pit, so as to bring them early and well into bloom; bottom heat of such a pit from 75° to 80°, top heat from 60° to 65°, with air to keep sweet, and to warm the sun-shines.

GREENHOUSE.

Chrysanthemums will be the better for manure waterings, and so will Cinerarias and Chinese Primroses, especially if the latter are in smallish pots, and at this early period they will bloom better if the pots are not too large. Camellias may also require a little thinning of their buds; and Ericas and F. racemosa should stand by themselves, so that the former at least may receive more air than is given to the bulk of the house. In watering at this season care should be taken not to spill water about, for careless waterers will make as much slopping as they would do in summer, when the more moisture about the stages and floor, the better it would be in fine weather. Now, every plant should be examined separately, and receive what it needs and no more, for all that runs over and is spilled on the floor, or shelves, will rise by evaporation, and be condensed against the roof, and in frosty weather when there is heat enough to melt it, it will fall over the plants like a cold sleet shower. When watered the water should not be lower than 50°, the plant should have enough to moisten all the roots, and receive no more until it wants it. Kinging the pots with the knuckles will soon tell if the soil is dry or not, as a dull sound will be emitted if the soil is wet, and a sharp sound if dry. Extra moisture at this season, however, present in the house, just speaks of extra attention necessary, extra firing, and, after all, extra likelihood of disappointment. The frost stopped us in clearing up the pleasure grounds; and the snow with its white mantle hid all defects, now we are at it again, getting the beds and borders cleared, though the leaves are not all down yet, and, therefore, we shall have more work in store. Those left seem battered and fixed on, which is not often the case when the frost comes severe at first. That is not the worst of it: what are gone are gone indeed, the high winds have blown them I do not know how far off—a serious thing for me, not only as respects those in the pleasure grounds, but also those in the park, as from standing high the neighbouring valleys after such winds get all the benefit of the leaves, which I depend upon almost entirely for what little help I must have in getting artificial heat from fermenting substances. They collect in woods, it is true, but it is no use thinking about them; the worst of it all is, that there is no use grumbling, for if I did I should find some telling joke all over the neighbourhood about leaves at my expense. It is hard to keep down all species of coarctousness when I go to some large place and see wagon-loads of leaves lying unranked, and think what I could do with them if I could have them.

When the beds are all cleared, and the grounds cleared up, and the walks switched and rolled, then the beds intended for bulbs may be nicely prepared for the purpose; and if the bulbs were placed thickly in reserve-beds, as advised some time ago, they may be moved any time when the weather is suitable and the ground all right and favourable, and hardly ever feel the moving, and will thrive all the better from the ground being well prepared for their reception.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the department writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E. C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

TEUCHEMUS CAFFENSIS (N. H. P.).—You have it correctly named. In a pot it grows shrubby about 2 feet high, but trained against a wall, will reach to the height of 8 or more feet. The *G* in *G*ishmus is pronounced like the same letter in *G*eece.

MELONS IN A PIT—WIREWORMS' H.—A *Constant Reader*.—You will keep the heat longer than fermenting material. The Melons will be best planted near the back, as the flue is there, and then be trained down within 12 inches of the foot. Could you contrive any means of siphoning in your days, leaving openings for the heat getting out, and upright drain-pipes in front communicating with open drains, p. s. show your best and most successful plan, and a sort of electric current the flue? This would give you a better circulation of heat in the house. You would see lately how a pit could be heated by a flue placed in the ordinary way. Orion is as good a new Melon as you could have, and the Beechwood has good as any though old. The gas water might cause the wireworm to fit, but the most effectual plan is to treat the soil with a sort of electric current and strip shield all over the ground, just beneath the surface, and go round and examine them every morning.

BOXES FOR MACHINES (H. H.).—As you cannot grind them, have them broken into small pieces, dissolve them in sulphuric acid, and mix the compound with coal ashes or earth.

FLEAS ELASTICUS—SOLANUM TUBEROSUM (A *Reader*).—Both plants will do well in the temperature of 50° to 60° in winter. The plants should be kept in a little water in winter; if the pots stand on the ground or on a moist slab, the Solanum will want water according to the heat you give it, and the character of the weather as to sun or shade. It is not, however, a great drinker in general. The Fleas will relish a little extra heat in summer to prevent green fly.

WOODEN TANK LIVERING (A *Subscriber*).—You had better take up the bottom and think as to what you do, if the chinks are so open as you say. If the boards are well seasoned, heat at the sides, and turned or not tanned, there would be no leakage so long as water was kept in. Of course, if left dry for months the joints will get so done, there will be no seepage, but if you have a hole in a side, or a crack in the bottom, you must stop it and then seal up your tank, giving a good airing to the tanks of the house.

PLANTING STRIPS (E. H.).—The beginning of October is the best time to pot off *L. Jaxia*. A rough peaty compost is the best soil for them, and the same treatment as for *Calceolarias* and *Cinerarias* in cold turf pits is the best of all modes of growing them. They may be planted, however, until the end of the month.

WINTERING CINERARIAS (R. B.).—The best way to winter *Cinerarias* is in pits and frames from which frost is merely excluded; and if they are in strong, rich, loamy soil, which needs as much air as each fine day of a whole winter will afford, or in other words the whole lights ought to be off in the middle of mild dry days.

PRESERVING PEAS FROM MICE (O. P.).—We are told that there is no effectual way of keeping plants from being eaten by mice, and *Persian* and *Spanish* Peas, nor Peas nor Beans from the mice. Fresh s of has been known to put mice, rats, and cock plovers on the verge of death for a week or two, by sprinkling a good dressing of it all over the rows or beds; but so soon as it became wet, it lost its power against the vermin. The best way is to use a good net, and to keep them all striped up and put in along with Peas and Beans, with an odd egg or two from the beginning to keep mice from garden Peas. But as no enemy of the gardener is less difficult to catch, that mode is the usual protection aimed at. Two inches in depth of coal ashes put over the bed and rows of Peas we have found the most efficient protection against mice.

PRESERVING TROPICUM ELEGANS (E. H.).—The best way to keep *Tropaeolum elegans* the *Crystal Palace Tropaeolum*, is to make cuttings of it in September, to have these well rooted by the first day of October, and from that day to the first day of March to treat the roots cuttings exactly and in all respects like *Mignonette*, that was sown in August to flower next May. You will find the best *Tropaeolum elegans* that if they get "too dry they wither up, and if too wet they rot." But mind you, cuttings of the Oak and Scotch Fir will do just the same, and so would any other plant.

BIRD-ROOFER (See *Gleaner's Talismans*).—Yams is a very poor combination. However, this is the best you can do with it. 1st, The *Lotella*, 4 inches in the ribs, and 6 in the plant from the foot of the roots. 2nd, Variegated Abyssin, 10 inches from the *Lotella*, and 8 inches plant from plant. 3rd, Dwarf Margold, 8 inches from the Variegated Abyssin, and to plant three rows of it 4 inches the one from the other row, to make one good row as it were. 4, *Tropaeolum elegans*, just where you please and 1 foot apart. *Portula* *bankensis* is easily peezed down. It requires a moderately fertile loam. *Hibiscus tenuis* *lanceolata* cuttings require heat in the spring. Cuttings of every softwooded plant, whether hardy or not, require heat to induce them to root at that season.

ALMOND CRICKETS (J. H. H.).—Much obliged, but the almond you refer to is far too contemptible to require any notice.

AUSTRALIAN IVY.—(J. B.) wishes to know if the so-called Australian Ivy is a true *Hedera*. It is a hardy, strong-growing, evergreen climber. There is an Ivy native of New Holland, *Hedera macrophylla*.

LYING STRING GREEN (J. R. A.).—We do not remember publishing a receipt for this; but lying the net for lark-catching brown is preferable, and that is done by dipping the net into a strong decoction of nut-galls.

DEUTZIA GRACILE LEAVES DECAYING (A *Irish Subscriber*).—The roots of the plants are kept to rot in water in autumn. Put the pots under shelter before the heavy rains and dark nights of autumn occur.

PROPAGATING AGAPANTHUS UMBELLATUS.—Will you state when and how *Agapanthus umbellatus* may be best divided for propagation? I have little to cut this year, but have generally thereby hindered the flowering in the following season. Will it part easily at any time without cutting?—*C. GREEN, Staffs.*

The best way in April or very early in May is the best time to divide *Agapanthus umbellatus* for increase, and there is no other way of doing it than the way you have proceeded in that respect for so many years. Divide up the roots of the heavy plants and divide the roots of autumn occur. The roots of the plants of the ball, before it is practicable to reach where the different branches of an old plant join together in order to separate them. The reason is this—The feeders are so strong and so numerous in this *Agapanthus*, that by the time it is too old to bloom, the soil is all gone, and the ball is made out of the roots which have rotted, so that no patience or ingenuity can separate them without cutting. Even if the ball was washed by pipe and hose till there was no particle of soil left among the roots, it would take a week or ten days to undo the roots without breaking them.

STREPTING HEMERA ELEGANS (J. M. E.).—The leader of a *Hemera* may be cut or pinched back at the end of the first season's growth, or any time during

December, and to any extent, and the side shoots will bloom all the stronger. But how would a grey-headed buck with his tail and ears cut after the way they dock tailers? Just like a Humca without the leader. When a Humca is rightly grown, the leader is the weakest shoot of them all, and it never can rob, in the smallest degree, any one of the side shoots. But few plants are worse grown than Humcas. We have not seen ten well-grown Humcas for the last ten years. To make a Humca, you should set slanting leaves falling over the sides of the pot or tub; the bottom shoots 10 feet from top to tip, and sweeping the ground, and 7 feet from the top of the leader, with the cone in one mass of bloom, are evidence of a Humca well cultivated.

ICE-HOUSE (H. Wilson).—Mr. Peaton says he never wrote a word about building an ice-house—that is, an ice-well in a bank of earth. It is a mistake. George Johnson, who found it in 1842, bearing in the lake of Dunse Castle, Berwickshire. It is now frequently found in other waters of England, Ireland, and Scotland, and wherever found becomes a serious injury. Locks, canals, mills, and fish-ponds, have all been choked with it; and no means of eradication it has been discovered. It is probably synonymous with *A. Verticilli* of the American Flora. Swans are remarkably fond of it, and keep it well under in the waters they frequent. By constantly cropping it down they sometimes eradicate it, and an instance is published where the swans ceased to thrive so well after this weed disappeared from their lake.

MIXED HERBACEOUS BORDER (An Old Subscriber, Wiltown).—We will publish something on the subject next week. We shall be obliged by any of our readers sending us an account of any mixed herbaceous border or bed which they consider well planted and managed. The account should give a list of the plants and the order in which they are planted.

FLOWER-GARDEN PLANS (J. C. Macraes Abbey).—Buy our "Flower Gardening for the Many," free by post for five penny postage stamps.

NAMES OF PLANTS (F. L.).—1, *Nematanthus longipes*; 2, *Othonna crassifolia*; 3, *Silene acaulis*; 4, *Jasione umbrosa*. (H. J.)—1, *Artemisia*; 2, *Araliaceae* plant not recognised; 3, *Arabis laterifolia*; 4, *Aralia nudica*; 4, very like *Erythronium hispidissimum*, but it is different to name plants from the leaves only without flowers. (J. D., Dundee).—1, *Euphorbia helioscopia*; 2, *Lycinis vesperina*; 3, *Galeopsis tetrahit*; 4, *Fraxinus vulgaris*. (K. M.).—1, *Lytium adanatum*; 2, *Clethra arborea*. (H. B. Reynes).—A good form of *Polystichum aculeatum* var. *lobatum*, with multiple apex. The Auricular leaf looks diseased: at any rate, the marking it a true variegation is not desirable. (J. T., Amouthill).—1, *Gymnogramma elonchoclasa*; 2, *Adiantum formosum*; 3, *Asplenium adnatum nigrum* (slender variety); 4, *Woodwardia (Boadia) cuneata*; 5, *Polystichum angulare*, var. *prolificum* Wollaston.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE IMPORTANCE OF POULTRY.

ALL our readers will recollect the "Sleeping Beauty." The older ones may no longer take any interest in the tale, but its associations will be with their youth, and however calm and pleasant middle or advanced age may be, there is a shade of sadness when past youth is thought of. It is a thing that can never return. To the young the old nursery tale is full of charms. The animals outside, the porter at the gate, the guards, the lords and ladies in waiting, the servants of every degree, all sleeping till the right person comes; then one sneezes, and another sneezes, till all wake up.

There is another tale not so well known perhaps. It concerns an old woman who went to market to buy a pig. It was necessary, in order to reach home, she should get over a stile; she did so easily, but the pig would not. She then endeavoured to press every mortal person and thing into her service, with a view to their co-operation in coercing the obstinate animal. Dog, cow, butcher, fire, water, rope, all were asked in vain, till one began, and then all set to work, and the old lady and her troublesome bargain reached home safely.

Now, to our mind, the poultry question has been sleeping for many years. Two wicked fairies have bewitched it; one has tangled large farmers the question is *infra dig.*, the other has pool-pooled the thing altogether: therefore, houses and farms have been untenanted, so far as poultry is concerned; positive advantages are thrown away, and opportunities of making money are set at naught. We have no statistics, but we are in a fair way to have them; then we shall be surprised. Few persons, if any, are prepared to find the magnitude of poultry interests.

There is a question becoming more important every day. It is the supply of food for mankind. What if the new theory be a correct one, that while the numbers of inhabitants increase yearly, production has reached its acme, so far as the old channels are concerned. Those who hold this to be true, point to the sea as the only resource; but poultry may also play its part. France produces yearly 3,715,200,000 eggs; she consumes and exports between six and seven millions worth of

poultry every year. Few things are more nourishing; none are capable of greater variety of cooking; and, we think we may add, nothing is so suited to the taste of every man, woman, and child as an egg. It is computed that France consumes every year nearly four millions of pounds weight of food in eggs only.

We know not what we eat in this pleasing form, but we know we import many millions that we might produce ourselves, and that if twice the present number were taken to market, there would at all times be a ready sale for them. We know the old mariners, in both army and navy, believe the services lost and gone to the dogs, because soldiers are no longer carefully strapped and bandaged, so that they can do nothing but stand upright; because the useful rife is substituted for harmless brown bees; and because it is no longer necessary that, on grand occasions, a man should have a regulation "queue," weighing not less than a certain weight, fastened to the collar of his coat. In the sister service there are those who shake their heads ominously because a parcel of boys are put in command when an admiral, of less than seventy, hoists his flag; they hate the "noisy devils that go by steam," and mourn the day when first-rate seventy-two's waited for wind and tide and rendered invasion impossible. So in civic life, there are people yet to be found who are eloquent in praise of the old four-inside post-coach, and hate the nasty railways—time for a cosy cup of tea whenever they changed horses. In all these cases every improvement is treated as a mad innovation. It is said that in Elizabeth's time an act was passed to prevent any addition to London, on the ground that so many people would be brought together, it would be impossible to feed them.

Ridiculous as these notions may be in every case, they are not more so than that which considers poultry beneath the notice of an agricultural society. The Royal, of that name, adopted it for a time, long enough to prove it was a valuable auxiliary to their funds, and then it gave it up. Some laughed at it, and others talked about cocks and hens. Fulton was laughed at the first time he tried his marine steam engine; and the first man who discovered the power of steam was consigned to a madhouse. The adoption of poultry, as a pursuit, by those engaged in agriculture, or those who have space and opportunity for rearing it, cannot compete with these great things and discoveries; but that which adds millions of pounds weight annually to the food of a country, or millions of pounds worth to the yearly produce, cannot, or at least ought not, to be lightly thought of. Too much praise cannot be given to such a society as that of Birmingham, not only for their enterprise and perseverance in carrying out a great undertaking, but for that sound judgment which took at once a correct view of stock, and offered noble premiums for cattle, sheep, pigs, poultry, and roots.

In walking through the sleeping-courts we have at last heard the sneeze—that is the prelude to waking. Societies are everywhere taking up the question; magazines make it the subject of their papers; and thinking men who care for fowls no more than they do for sheep or cattle, except as articles of food, are not only making inquiry, but are willing to invest capital in the production of eggs and poultry.

We will conclude this by informing our readers there is a show at Perth, under the immediate patronage of Lord Kinaird, on the first, second, and third days of January. The prize list is a liberal one. In the classes for Dorkings, Silver Grey and Coloured, each has four prizes of £5, £4, £3, and £1. The prizes for Dorkings alone amount to £31. Mrs. Ferguson Blair, and other exhibitors from Scotland, freely enter our southern lists, and are heard of at all our great shows. We hope some of our good breeders will not fail to return the compliment, and that goodly entries of English birds at Perth will prove that we like good opponents; that we return courtesy, and that we are glad to give every support to that which we believe to be far more important than anything that can be called a fancy.

OATS FOR POULTRY FOOD—POINTS IN A DORKING COCK.

SHOULD ground oats for poultry be also sifted, or given husks and all?

Which is considered most objectionable in a Dorking cock, a speckled breast, or a white feather in the tail?—J. F. N.

[The ground oats should not be sifted, the entire corn should be ground as fine as possible, and nothing taken from it. We

do not consider either of the points you mention as objections in a Dorking cock. Many people do, and we fancy they would rather forgive the white tail-feather than a spotted breast.]

SCOTTISH ORNITHOLOGICAL ASSOCIATION.

The third annual Exhibition and competition of fancy Pigeons and Canary birds, under the auspices of this Association, was opened on the 21st, in the Trades' Hall. The Exhibition was a most superior one. In the Pigeon department, the competition, owing to the many excellent entries, was very keen; and amongst the entries for the special prizes were some very beautiful birds. The class pairs were numerous; and, in the Powder department, the birds were very good. The Carrier Pigeons were also numerous, and some of them exceedingly rare. In the Canary bird department some of the finest birds we have seen were exhibited. The following are the awards:—

PIGEON DEPARTMENT.

EXTRA PRIZES.

A Silver Cup, for the best Three Pairs, one pair each, **CARRIERS, POWERS, and SHORT-FACED ALMOND TUMBLERS**—P. Eden, Manchester. A Silver Medal, for the best Pair **Black POWERS**, bred in 1861—J. Millar, Glasgow.

A Silver Medal for the best **Yellow POWER**, cock or hen, bred in 1861—G. Ure, Dundee, hen.

A subscription Silver Medal, for the best Pair of **POWERS** (black and yellow excepted), bred in 1861—G. Ure, Glasgow.

POWERS (Black Cocks).—First and Second, J. Millar, Glasgow.

POWERS (White Cocks).—First, P. Eden, Manchester. Second, W. Smith, Halifax.

POWERS (Blue Cocks).—First, G. J. McLean, Edinburgh. Second, P. Eden, Manchester.

POWERS (Red Cocks).—First and Second, G. Ure, Dundee.

POWERS (Yellow Cocks).—First, P. Eden, Manchester. Second, J. Hink, Glasgow.

POWERS (cock any other colour).—First, J. Hink, Glasgow (Mealy). Second, W. Wallace, jun., Glasgow (Checker).

POWERS (Black Hens).—First and Second, G. Ure, Dundee.

POWERS (White Hens).—First, P. Eden, Manchester. Second, G. Ure, Dundee.

POWERS (Blue Hens).—First, W. Smith, Halifax. Second, G. Ure, Dundee.

POWERS (Red Hens).—First and Second, G. Ure, Dundee.

POWERS (Yellow Hens).—First, P. Eden, Manchester. Second, W. Smith, Halifax.

POWERS (Hens any other colour).—First, J. Hink, Glasgow. Second, W. Smith, Halifax.

CARRIERS (any colour).—Silver Medal, P. Eden, Manchester.

CARRIERS (Black Cocks).—First, P. Eden, Manchester. Second, J. Muir, Glasgow.

CARRIERS (Dun Cocks).—First, T. Colley, Sheffield. Second, A. L. Sulvester, Birmingham.

CARRIERS (Black Hens).—First, P. Eden, Manchester. Second, J. Bairstow, Halifax.

CARRIERS (Dun Hens).—First, J. Bairstow, Halifax. Second, W. Cannon, Bradford.

SHORT-FACED ALMOND TUMBLERS.—Silver Medal, P. Eden, Manchester.

SHORT-FACED ALMOND TUMBLERS.—First, P. Eden, Manchester. Second, W. Cannon, Bradford.

SHORT-FACED TUMBLERS (Mottles, any colour).—First, P. Eden, Manchester (Black Mottles). See nd, I. Monkhouse, Kendal (Black Mottles).

SHORT-FACED TUMBLERS (any other colour or variety).—First, M. Stuart, Glasgow (Red Agates). Second, H. Wardle, Newcastle (Kites).

FANTAILS (any colour).—A silver medal, G. Ure, Dundee (White).

FANTAILS.—First, G. J. McLean, Edinburgh. Second, G. Ure, Dundee (White).

JACOBINS (any colour).—A silver medal, J. Peel, Usworth, Sunderland.

JACOBINS.—First, J. Sharp, Johnstone. Second, J. Greig, Inverlorn.

TRUMPETERS.—First, W. Wallace, jun., Glasgow (Black Mottles). Second, W. Cannon, Bradford.

TURBETS (any colour).—A silver medal, P. Eden, Manchester (Black).

TURBETS.—First, R. Pickering, Carlisle (Blue). Second, W. Cannon, Bradford.

OWLS.—First, W. Smith, Halifax. Second, W. Cannon, Bradford.

NUSS.—First, F. Key, Beverley. Second, J. W. Edge, Birmingham.

MAGPIES.—First, J. Ziegler, Edinburgh. Second, W. Smith, Halifax.

RUNTS.—Prize, W. Wallace, jun., Glasgow.

OTHER TUMBLERS.—First, A. Morrison. Second, J. W. Edge, Birmingham.

OTHER BELLES.—First, G. Ure, Dundee. Second, W. Cannon, Bradford.

JUDGES.—Mr. Andrew Cowan, Ayr; Mr. Matthew Hedley, London; Mr. Henry Simpson, Newark.

CANARY DEPARTMENT.

EXTRA PRIZES.

A piece of silver plate, and £1 1s as a second prize, for the best pair of Scotch fancy, the produce of 1860, or prior thereto; the same to be yellow cock and buff hen, or buff cock and yellow hen.—First, G. Buchanan, Glasgow. Second, J. Halley, Carron.

A prize for the most portable cage, suitable for carrying Scotch fancy birds to exhibitions.—Prize, W. Alexander, Edinburgh.

SCOTCH FANCY.

Special and Association Prizes for best Cock, yellow or buff.

YELLOW COCKS.—First, R. Patterson, Glasgow (special). Second, W.

Murray, Edinburgh. Third, G. Ayton, Glasgow (special). Fourth, D. Gunn, Glasgow (special).

BUFF COCKS.—First, J. Wren, Paisley (special). Second, W. Hunter, Kilbirnie (special). Third, J. Armstrong, Glasgow. Fourth, D. Gunn, Glasgow.

Special and Association Prizes.

YELLOW HENS.—First, A. Gibb, Paisley (special). Second, W. McLeod, Glasgow. Third, J. Halley, Carron. Fourth, A. McLure, Glasgow.

BUFF HENS.—First, J. White, Paisley (special). Second, J. Johnston, Kilmarlock (special). Third, J. Ritchie, Edinburgh (special). Fourth, G. Horsburgh, Glasgow.

BELGIAN FANCY.

Special and Association Prizes.

YELLOW COCKS.—First, J. Ruthven, Glasgow (special). Second, J. Dundie, Glasgow. Third, R. Somerville, Edinburgh.

BUFF COCKS.—First and Second, J. Ruthven, Glasgow (special). Second, J. Simpson, Edinburgh.

Special and Association Prizes.

YELLOW HENS.—First, J. Simpson, Edinburgh (special). Second, J. Birkett, Dundee (special). Third, J. Thorp, Dundee.

BUFF HENS.—First and Second, J. Ruthven, Glasgow (special). Third, J. Simpson, Edinburgh.

PIEDFOLDS.

YELLOW COCKS.—First, T. Pate, Beith. Second, N. McLean, Glasgow. Third, A. McLeish, Perth.

BUFF COCKS.—First, D. Duncan, Carron. Second, J. Jamieson, Balgray. Third, A. Conn, Glasgow.

YELLOW HENS.—First, T. Pate, Beith. Second, J. Vine, Paisley. Third, R. Laurie, Glasgow.

BUFF HENS.—First, J. Jamieson, Balgray; Second, W. Alexander, Edinburgh. Third, W. Wilson, Manclieve.

GOLDFINCH MULES.

YELLOW COCKS.—First, W. Kirk, Dunfermline. Second, W. Wilson, Manclieve.

BUFF COCKS.—First, W. Kirk, Dunfermline. Second, J. Duncan, Glasgow.

JUDGES.—Messrs. George Grant, Paisley; for George Crawford Beith; James Graham, Kilmarnock; Jacob Beoby, Carlisle; Charles Gordon, Glasgow; George Ayton, Glasgow.

FEEDING GOLDFINCHES—KEEPING PIGEONS.

I HAVE had a Goldfinch for about three years, and have fed him on hemp, canary, and rapeseed, and until the last few weeks he has thriven on that diet, but he now seems out of health, for he does not sing, and sits with his feathers ruffled. He moulted some weeks ago, so he ought to have recovered from the effects of that.

I am aware that my plan of feeding is a wasteful one, as the bird, preferring the hemp, scatters the other seed about in order to reach it. I have tried leaving out the hemp, but find it invariably makes him sulky. When he was in health I once or twice gave him no hempseed for a day or two, and he was always in ill-humour, but was restored to cheerfulness by a supply of his accustomed dainty. I give him occasionally thistleseed and groundsel. Can you suggest a better diet?

Will you at the same time be kind enough to answer another question? I wish to keep a few fancy Pigeons for amusement. Which do you consider the prettiest and most desirable kind?

—A LOVER OF BIRDS.

[Your complaint respecting the Goldfinch is only another example of the evil effects of giving cage birds hempseed. The hemp plant contains an extract of an intoxicating nature resembling opium, and the seed is found to have an exhilarating and exciting effect on most birds. I would advise you to wean your bird gradually from both hemp and rapeseed; give him good canary seed, shell-d oats, and a little mawseed; let him have plenty of groundsel, blackweed, and the seedly heads of thistles and dandelions. Probably there may be an obstruction of the oil gland on the rump; if so, gently press out the coagulated oil and matter, but do not cut or prick the swelling, as the matter ought to pass out of the natural opening; then anoint the part with fresh butter or pounded loaf sugar.

So much depends on taste and fancy that it is impossible to advise in the choice of fancy Pigeons; all are beautiful. You had better visit some show and choose for yourself. If well fed they will do no harm in a flower garden, as they would only eat a little salad. The rabbit-hutch mentioned, if provided with a couple of nests, and hung up out of the reach of stray cats, would accommodate one pair of Pigeons. They may be procured at any time, and to prevent their flying away, they should be confined for a few days till they become accustomed to their new abode; three days is often long enough, but for safety I would advise a fortnight, especially if wild. If let out too soon,

their natural desire for home will induce them to try to return there, and as they might not be able to find it, they would very likely be lost. They should be so confined that they may see about their new place, that their sight may assist them in recognising it when let out. For food—tares, beans, lentils, and buckwheat, are among the best, with clean water, a lump of salt to peck, and some grit, as old mortar or broken oyster-shells. For nest-building, birch or heath twigs are preferable to straw; and a little sulphur dusted among their feathers and in the nest will help to keep them free from vermin.—B. P. BRENT.]

THE SUPER-POSED HIVE DOES NOT BECOME THE STOCK-HIVE.

My attention has lately been called to an article in this Journal in which "A RENFREWSHIRE BEE-KEEPER" states, as his opinion, that a queenless hive placed on another possessing a queen will, after the excitement consequent upon the operation subsides, become the stock-hive. This is certainly contrary to my experience during a careful observation of many years. I do not consider that the pollen-laden bees would give themselves the trouble of traversing the combs of the lower hive to reach the seat of breeding in the upper box, but in all instances convert this hive into a store-house, as it is known that they prefer storing at a distance from their entrance. Even in the case of a supered stock-hive the combs, as they are worked down into the lower box, become the seat of breeding, not of honey-storing; and in most instances a transference takes place, the supered stock becoming to a great extent the storing-hive.

My experience, then, amounts to this—that in no instance have I found the top hive become the stock-hive; and therefore I can endorse the statement of "A DEVONSHIRE BEE-KEEPER" that the lower box is the seat of breeding, the upper hive being for the storing of honey.—G. FOX, *Kingsbridge, Devon.*

THE STORIFYING SYSTEM.

HEARTILY concurring with your much-esteemed correspondent "A DEVONSHIRE BEE-KEEPER," that the development of truth is the main object your correspondents aim at, and my only motive in having the temerity—a comparatively young bee-keeper—to call in question the editorial reply in "A. W.'s" case, page 38, you may judge of my disappointment at observing the very decided opposite opinion expressed by your excellent Devon contributor as to my experience of such a case, and my satisfaction at so high an authority as our paternal one, Mr. Brown, of Stewarton, spontaneously stepping forward to decide by such a lengthened experience the point at issue. That gentleman, although being personally an entire stranger, if I mistake not, I have on more than one occasion delightedly inspected at several Glasgow warehouses many beautiful octagon trophies of his apian skill.

The same motive alone impels me to notice "A DEVONSHIRE BEE-KEEPER'S" remarks on this point under "Super-posing" at page 139. It is an established rule in storifying that all entrances be closed but the lowest, and in that manner I have wrought a set of boxes attaining a height of 30 inches: to overcome the objections that might be brought up against such an altitude, suggested to me, the "adapter plan," described in No. 5. There being more than one entrance left open would only afford an attraction to robbers, and in no way affect the result as your correspondent supposes.

His adducing the well-known fact of the honey being stored above must surely tell against his own argument, and prove a powerful attraction towards the ascension were not its being so stored an indubitable proof of the premeditated intention of the bees to ascend at the approach of severe weather.

Their descending on the advent of summer heat is also an established fact ascribable to the same influence of genial warmth that causes the opening of every downy bud, but foreign to the subject on hand, as long before "A. W.'s" lower box would have been removed, and the upper hive, agreeable to his wish would have been ready for swarming.

It is quite a common practice of storifiers removing the lower portions of their hives at the end of the season and replacing the same as may be required for breeding the following season, with the most beneficial results.

I have never experienced a more than usual number of drones

while working on this system, nor can I coincide in your correspondent's opinion as to the large extent of drone-comb in the hive alluded to by me at page 59, the increase of the male sex being gradual season after season till the last, when they exceeded all due proportion, thereby rather establishing the growing age and consequent decay of the royal mother.—A RENFREWSHIRE BEE-KEEPER.

LIGURIAN PROWESS.

IN the JOURNAL OF HORTICULTURE appears an account of a violent onslaught upon a solitary Ligurian stock by "all the bees in the neighbourhood;" but which resulted in the Italians being "able to hold out against the attack." As I happen to be a sufferer from a somewhat similar occurrence, in which Ligurians were the aggressors, I am tempted briefly to relate the circumstance.

In September last I was possessed of a strong swarm of common bees, with a remarkably fine and prolific queen, which had filled its hive with combs; but not being heavy enough to stand the winter, copious feeding was resorted to by means of two small bell-glasses filled with liquid food, tied down with lino, and inverted over orifices in the top of the hive. A few marauding Ligurians from the neighbouring apiary of "A DEVONSHIRE BEE-KEEPER" at first intruded themselves, and shared my bounty by licking the food from the outside edges of the bell-glasses. On perceiving this, I excluded them by carefully swathing the glasses in a couple of handkerchiefs, and all went well until I administered the last dose of syrup at nine o'clock in the morning of the 24th September. During my absence that morning a very great commotion was observed in the neighbourhood of the hives. On my return, about two o'clock, I was met by the exclamation, "The bees are swarming!" Putting on a bee-dress, I hastened to see what was the matter. Alas! a dreadful conflict was taking place! the Ligurians from my neighbour's apiary having fallen on my poor unimpug stock. The commotion continued until about five o'clock in the afternoon, when it subsided, and I found nearly all my bees killed, the combs torn to pieces, and the box as completely cleared of honey as if the bees had died of starvation!

Now, I wish to ask "A DEVONSHIRE BEE-KEEPER," or any other of your numerous apian correspondents, what is the best means of securing our native bees from the attacks of such insatiable plunderers, and what legal remedy we have against those who have imported these foreign marauders?—S. D.

[If the "native bees" will not stand a brush with the Ligurians, we counsel you to discard them altogether. Legal remedy you probably have none; but we are sure "A DEVONSHIRE BEE-KEEPER" will be happy to afford you a civil one, by assisting in Ligurianising your entire apiary.]

PARTHENOGENESIS IN THE HONEY BEE AND IN MOTHS.

As my name and address appear on the same page with Col. Newman's last polite communication, I hope if he should have the opportunity of forwarding to me a drone-breeding queen or assisting me in my researches in any other way, he will not hesitate to avail himself of it; and, by so doing remove me from his category of "unknown friends."

I believe myself to be the first Englishman who has attempted to verify Von Seebold's researches into the phenomena of parthenogenesis in the honey bee, and have thus far found him perfectly correct. Next spring I hope to prosecute my investigations still further, and have little doubt that they will turn out equally confirmatory of the discoveries of this distinguished German naturalist.

Now, with regard to my meaning when I stated "that a drone-breeding queen is a virgin queen," I cannot accept the limitation proposed by the gallant Colonel, since I am satisfied that this is always the true state of the case, and shall be greatly obliged to any one who may enable me to test the correctness of my belief by the dissection of as many drone breeders as possible.

Whilst on the subject of parthenogenesis I may remark that this phenomenon has been observed in some species of moths as well as in the honey bee. In particular I would mention the silkworm moth, whose virgin progeny is both male and female.

In the singular case of a swarm issuing in July from a stock

* Any specimen for examination should be sent alive.

which had killed all its drones in June, I should imagine that if the hive had been examined at the time it would have been found that a second laying of drone eggs had taken place.

Without attributing the circumstances to "disease," I have much pleasure in confirming Col. Newman's observation that queens often depart from the usual routine of egg-laying, and that some queens are much more prolific than others.—A DEVONSHIRE BEE-KEEPER.

PARTHENOGENESIS IN THE QUEEN BEE.

I CAN fully enter into the feelings of intense satisfaction with which "A DEVONSHIRE BEE-KEEPER" made the post-mortem examination of a drone-laying queen, and found the result entirely corroborative of the investigations of the German naturalists.

It is much to be desired that his indefatigable labours may be rewarded also by the proof of parthenogenesis through the positive line of evidence, that of direct observation that copulation has not taken place.

The proceedings of the drone-laying queens do not appear to have been particularly noticed, but the account is worth analysing. The weather was very unsettled, yet two sister queens were duly impregnated. The passage of the hive was narrow, but not so contracted as to obstruct the passing of the queen. The number of bees was small, occupying a mirror-hive, and comb was made slowly. Here, perhaps, we have some clue. May an ungenial temperature in the hive restrain the queen from the desire of leaving it, or does it so affect her system that copulation is ineffective? There is analogy to this in the vegetable kingdom. Flowers which resist the influence of pollen in England, become fruitful in the warmer climate of Australia.

It is not quite clearly stated by Mr. Briscoe, whether the queen had begun to lay before feeding was commenced. Might this have acted as a stimulant to produce eggs, or has a queen not the power to retain them after the fatal twenty days are passed?

I offer these suggestions in the hope that it will not be considered that the subj. is exhausted, and that no opportunity may be lost of throwing further light upon it. A fortunate accident may reveal much, or an experiment in autumn, where it can be ascertained that there are no drones within an area of four miles (it is very probable the flight of both queen and drone may extend two miles), and, above all, by placing the queen in the uncomb-hive, where she can be looked at every day towards evening, the evidence of fecundation being apparent for several hours.

Many apianians may be able to offer some facts, which if strictly accurate would be useful. I can speak with certainty of only one family in which the queen proved a layer of drones only. It was a second swarm, and filled only about one-third of the hive with comb. The whole of the bees disappeared when sent to the moor, leaving worker-comb deformed by the cooled drone-brood.—INVESTIGATOR.

UNITING BEES.

If Mr. Hood, who wrote in your issue of the 5th, had placed his full hive in a common kitchen metal pot so that the hive would rest on the sides of the pot, but not on the bottom of it, placing as he has done his empty hive closely on top of his full one, and then with two light sticks strike the sides of the pot, he would drive every bee into the empty one in fifteen minutes, when it should be immediately taken away. I have removed bees in that way in the early part of last July, without leaving one in the full hive, nor losing half-a-dozen of my bees.—ALPHA.

SUPER-POSING—INTRODUCING FOOD DIRECTLY INTO THE COMBS.

YOUR excellent correspondent, "A REXFORDSHIRE BEE-KEEPER," appears so thoroughly satisfied of the correctness of his opinion, that bees are disposed to adopt the upper compartments of storied hives as their breeding place, that I must leave experience to convince him of his error, and in the meantime beg to shake hands and agree to differ with him.

Singularly enough, in the very article which precedes the one in which he resists this opinion, he records how in breaking up two sets of storifying-boxes he finds the honey "stored chiefly in the upper box of both," whilst "the tier of bees," "the Ends" "to contain . . . a large quantity of brood." Surely

this fact might have suggested to him, that no tallanistic influence is required to induce our little favourites to obey the natural instinct which invariably prompts them to make their breeding place as near the entrance to their habitation as possible.

Whilst referring to this communication of our Devonshire friend, I venture to caution him and the rest of your apianian readers, against over-estimating the advantages of introducing artificial food by pouring it into the combs from "a long-piped tin can." I believe that even pure honey will not keep unless placed in the combs by the bees themselves, and I am very sure that all artificial compounds require to undergo a chemical change in the stomach of the bee before they can be stored in the combs, in such a state as to keep good throughout the winter. I have often tried this experiment, and have constantly found that the food is immediately transferred to some other comb, during which operation the requisite chemical change is, doubtless, effected; but there is also the same amount of labour, excitement, and loss of weight (I am not sure that it should be called "waste"), incurred, as takes place when food is administered by the bottle.—A DEVONSHIRE BEE-KEEPER.

VARIETIES.

PROPOLIS dissolved in spirits of wine or turpentine has been used for varnishing tin and other polished metals, tinging them a lemon colour, and protecting them from rust.

THE PLANTAIN.—The first plant of *Musa paradisiaca*, large Plantain, that fruited in Scotland was in 1789 in the Pine-store at Tynninghame, the seat of the Earl of Haddington. It had been long grown in a tub, and on becoming too large for the house was planted out in the bottom of the back pit. It flowered in course of the following summer, and produced thirty-two fruit which ripened to perfection, each being from 4 inches to 5 inches in length, and $\frac{1}{2}$ inch in diameter. Several species of *Musa* have been fruited in great perfection, both by the late and present Messrs. McNab, in the Royal Botanic Gardens. M. Cavendishii, on account of its dwarf habit and easy culture, is now grown in many establishments as a fruit-bearing plant. It is of easier cultivation than the Pine Apple, and since these have been imported in such numbers, the fruit of the *Musa* is now held in greater estimation, and, with *Passiflora edulis*, are the only tropical fruits which have been successfully ripened to any extent in Britain. A house is dedicated to the cultivation of the latter fruit in the gardens of the Duke of Buccleuch at Drumlanrig Castle, where many hundreds of its fruit are yearly produced.—(Scottish Farmer.)

OUR LETTER BOX.

LEAVE IN A POORMAN'S FOOT (An Old Subscriber).—It is probable the swelling arose from a floor or gravel stone that has pierced the skin of the fall of the foot and caused inflammation. It is best to be cured gradually, and then open the swelling with a sharp lancet or razor. Diet or dining treatment should be wrapped in a piece of leather, and the foot examined to a glass tube. It may be nicely opened by a caustic incision, but it is best not to remove it.

BREEDING FROM CHICKENS (X).—It would be impossible to say how the evil of breeding from chickens on both sides would show itself. The general result is, sickly and bad constitutional produce; but it is not always the case. The fact that stronger birds are produced when the parent on one side or other induces those who are breeding, it is to advise in such matters to recommend the adoption of such a system.

WHITE FACE OF SPANISH COCKERELS (Jem).—Spanish cocks, nine months old, should be quite white over the eye. When caught and closely examined, there is sometimes a dash of red about the white over the eye. Where this is not visible to the eye at a few yards distance, we would not regard the bird; but if he is plain and decided, we should have no objection.

PARENTS OF CHICKENS (Jem).—Much of the size of all chickens depends on their food and treatment when young. As a rule, we think we need hardly say, 1-2 egg birds are the likeliest to breed large chickens.

FOOD FOR HENS, &c. (L. C.)—No mud will make an old hen lay in winter. Cochin-China pellets will fly during that season fed upon ground and unadrested ones, which is the best food for all poultry, with a little whole barley occasionally. Our "Poultry-Book for the Many" contains all necessary information on the subject.

YELLOW LEGS (EDMUND FOWLS, P. W.)—We cannot answer your question with any certainty till we know in what way the fowls were bred to death. We can hardly believe there is any mixture with the blood; the yellow fluid which you describe almost always exists on the crop of a fowl, especially after drinking and after a fowl is held up by the legs, it will run freely from the mouth, and mix with the blood. If the fowl be bed in the palate, or if its throat be cut, and it is then held up by the legs, the mixture will take place, but the two are entirely due to the other. Fowls want nothing thrown on the grass in wet weather. If a fowl and Indian corn or meal are not good food. Can be yourself to *arise* of potatoes, to lettuce, and to ground oats or barley; it is the worst as the better.

RABBIT, COLOURED (H. F.)—A self-coloured Rabbit is a Rabbit of one colour. A blue rabbit, which is a grey, fawn, and brown, certainly could not be entered in the self-coloured class.

WEEKLY CALENDAR.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 52.7° and 39.6° respectively. The greatest heat, 60°, occurred on the 7th in 1855; and the lowest cold, 14°, on the 5th in 1844. During the period 114 days were fine, and on 124 rain fell.

PRUNING SHRUBBERY AND FOREST TREES.

THE woodman ought to be now busy with his knife, his axe, chisel, or saw in cutting off superfluous branches, shortening in such as are robbing the others of due support, or, in other words, balancing the powers of the tree, so that every leaf may have due space to fulfil its functions. This ought to be the grand aim of the tree-pruner. It is evident that pruning consists of two branches—namely, thinning the trees on the ground, and judicious pruning in the branches, so that there may be a sufficient number of leaves fully exposed to the sun and light to draw up sap to develop growth, and when the leaf is fully grown to concoct juices to deposit the

albumen as it descends, which forms the wood annually, that increases the bulk of the timber.

To understand all this the pruner ought to know a sufficiency of vegetable physiology to appreciate the effect of too little or too much denudation of the trees he operates upon. How little this true science is understood by our woodmen, or even their head forester! Generally they are mere labourers who scarcely ever read a line on the subject, or ever think at all about the matter. They are directed to go into a certain plot of woodland and prune the trees, and the way they are to do it is to cut off close to the stem all the branches to a certain height. If thinning is to be done at the same time it is probable two or three will be directed to go before the others, and cut down such trees as are crooked, weak, or not likely to make good trees. This is done sometimes so severely that the cold winds have full play on the trees that are left—trees that had for, probably, many years been so protected by each other that now when so rudely and suddenly exposed to the cold winter blasts suffer so much from the sudden exposure as to require many years to recover strength to bear the change, and grow on again as they did before they were so stricken with cold. Then, to complete their discomfort, the pruners follow on and cut off all the side branches, leaving them something like brooms, or fishing-rods, with the sweeping part upwards. One would think no man with any brains at all would be so silly as to prune trees intended for timber in such a ruthless manner, yet it is, I am sorry to say, too frequently done. I have seen it repeatedly, and in parts of the country wide apart from each other.

The question naturally arises, How is a better practice to be attained? A thinking man will instantly exclaim, "Educate the men, put books into their hands, and see that the true principles of the art are explained to them by competent men. Good timber is

of the utmost consequence to our country, and every true lover of his country will see the necessity of clothing the forests of the land with rising timber, that will as soon as possible make trees large enough for the purposes for which it is required." In a necessarily short essay, I have only space to give a few brief hints on this truly interesting subject.

The first point is to take care that the thinning and pruning are commenced when the plantation is young. The trees should never be allowed to reach more than from 6 feet to 10 feet high before they are thinned. This is often delayed in order that the thinnings may be made use of for rails, posts, and stakes. Never was economy more misplaced. All the evils I have just alluded to must happen: therefore I say most emphatically, Do not exemptly so absurdly the old proverb, penny wise and pound foolish. Thin your young trees before the branches touch each other, and do not thin them too severely in one season.

Let the thinning be done the season before the trees are pruned. The branches of the trees that are left will shelter the stems from the cold winds. The following season these branches should be shortened in. If done in time, the knife will, in judicious hands, be the only instrument required. In plantations that have been neglected for perhaps twenty or more years, it may be necessary to use stronger instruments, such as the chisel, the saw, or the bill-hook, but I trust the day will come when these tools will be banished out of the woodman's vocabulary, and be thought and found quite unnecessary. The following season part of the branches may be cut in close to the stem, and the rest shortened in again. My great object is not only to protect the stem, but also to leave these branches to be furnished with leaves, always remembering that it is the leaves that furnish the organizable matter to increase the bulk of the stem. Even large bushy-headed trees may be greatly improved for timber purposes by thinning the branches, and shortening in those that are left.

Young neglected plantations, such as may be seen in various parts of the country, require very careful thinning and pruning in order to bring them into a better condition. Though there are ten times too many trees it will not do to cut down at once the nine that are but cumberers of the ground. Instead of that severe treatment, I would recommend taking out not more than one-third this year, and then let the rest remain two years longer. Then go over the wood carefully, and take out one-third more of the worst trees, and so on, thinning them every other year, and pruning moderately the alternate years. By this gradual thinning and pruning the trees that are left to form good timber will be found sturdy fellows able to bear the strongest blasts, and finally become very tolerable trees, not indeed equal to such as have been trained up in their early youth, but yet worth ten times as much as they would have been had they been left unthinned, unpruned, and uncared for.

The preceding hints the reader will easily perceive refer to deciduous trees—such as the Oak, Ash, Elm,

Beech, Larch, &c. Pruning evergreen trees—such as the Spruce, Scotch Fir, &c.—is a somewhat different affair. If these are pruned now they suffer more even than deciduous trees; I would, therefore, not prune them till March, and then it is particularly desirable to shorten in such branches as are intended to be removed entirely the season previous to their final close pruning. No branches on any tree should be allowed to remain on till they become large, because such large branches are so deeply inserted into the main stem that the latter is filled with knots just where the large branches were placed. Knotty timber, such as the Oak and Walnut, is sometimes, when sound, very valuable; but generally it is greatly inferior in value to such as is clean and straight.

The best season for pruning deciduous trees is decidedly winter—that is, from November to the end of February. If pruned later than the latter month many kinds—such as the Sycamore, the Birch, and Maple—bleed so copiously that the growth the following season is materially injured thereby.

T. APPELEY.

DOUBLE-GLAZING—DISA GRANDIFLORA— MIMULUS CUPREUS.

NINETEEN years since come next summer, the author of Rogers' conical boiler wrote to me from Sevenoaks, in Kent, to Shrubland Park, asking me what I knew of double-glazing hothouses, and informing me of a plan of doing so which he had in contemplation, and a most capital plan it was, and one that would do as much for the comfort of gardeners as his conical boiler did for those who could get coals which would not cake to burn in it. Rogers' conical boiler is still one of the best with unseaking coals; but for such coals as the Newcastle and others, which run together and "cake," as we call it, the conical boilers are not suited.

What he principally wrote to me for, anent his plan of double-glazing hothouses, was to ascertain, if possible, whether the idea was new or not; and I wrote to him to advise him not to say a word about it in print or in public, for the idea and the execution of it were just as old as the Empress Catherine of Russia. She was the first to take up the idea of double-glazing hothouses, and your humble servant was very probably the last person who meant to do his conical vinery as the Empress Catherine of Russia did her hothouses. But Her Majesty was not the author of double-glazing for all that. The practice was common in all parts of Russia since glass was introduced into that country, and is so to this very day and hour. All the windows of all who can afford it all over the Russian dominions are double-glazed. Even in the warmest and most southern parts of the empire, along the coast line from Balacava to the straits of Ymcale, our people found the windows double-glazed. The reason for double-glazing windows in Russia, is the fact that they keep out four times more degrees of frost than our windows do, which renders their windows as warm for their rooms as ours are to us and ours.

But double-glazing has been as common in our island of late years as it has been in Russia from the beginning, and yet some of our people talk as if it were a new discovery fresh from Paris or from America. Ask any of our people who have been down to see Balmoral, how the natives glaze their windows in Aberdeen, new and old Aberdeen. Or, ask any of the students who attended the Universities there for the last thirty years, how they escaped taking colds and sore throats when their bedroom windows faced the direction of Peterhead, their land's end in that quarter; and each and all of them would, should, or could tell the only bar against those occurrences was double-glazing; but that the Scotch boddies improved on the Russians by having double frames for their double-glazed windows.

If I recollect rightly, Mr. Rogers' idea of double-glazing hothouses was to have the houses all like as Mr. Rivers recommends so industriously. They were to be from 100 feet to 120 feet long and 24 feet wide, and glass all down to the ground line, back, front, and both ends. All the laps were to be made perfectly air-tight, except the lowest next the ground, and that one was to be open all the way round the house. Then if the top of the house or roof was ridge fashion, and not curvilinear, he had a contrivance to let the air move on or off to either side of the ridge as it listed, or rather as its different degrees of temperature determined, and all his upright glaz at front and back, communicated with the roof glass in the same way; so that a draught of cold air entering in between the double-glazing on

the front or south side would rise, as it warmed, to the roof, and cross the ridge to the north side, and as it cooled gradually it sunk lower and lower, till at last it got so heavy as to fall out from between the glass on the back or north side of the house. That was to be in the fore part of each day. In the afternoon the current would change from north to south, and in dull weather there was to be little or no current at all. But always the hottest part of the enclosed air was to be at the ridge or top part of the roof.

Now, when I wrote about my vinery that was to be, I said a one-inch common draining-pipe was to carry warmed air from a warm air-chamber made under three lights at the end of a range, through that range or three thirteen lights, and then discharge itself into the vinery, as Mr. Kidd discharged hot air into the conservatory. But that was not exactly what was then in the wind. The upright walls of three sides of the cube vinery were to be 18 feet high, all in double-glazing; the fourth side existed already in brickwork, well covered with established Vines. The warm air from the drain-pipe was to be discharged at the bottom into the cavity between the double-glazing, and the three sides were to participate in the benefit, if any, from the warm bore-pipe, just as Mr. Rogers meant the air to circulate in his plan nineteen years previously. I said the plan was growing in my head for so many years, and that was the longest root of the whole system. But my roof was to be different from his roof—I was to have two span-roofs east and west, over the cube, and my first idea was to glaze them as the same kind of roof of a new storehouse in the botanic garden at Oxford was done in 1852, and that was to have the south sides of the ridge roof glazed with tinted glass, or Hartley's rough plate, and the north sides with the cleanest and clearest twenty-two-ounce sheet glass. That would save anything inside from the scorching which happens at times from all clear glass, and save shading.

I changed that plan last April on studying a fine plan for a grand conservatory which was sent for the opinion of the Floral Committee. That was the best plan for roofing a glass house of all the plans I had ever seen or heard of—that is, a house of large dimensions, and with more roofs than one, if that is not taking the roof off the meaning. My cube of 18 feet to the side was a fleabite to a big house, and yet the walls of it were higher than they are ever met with in vineries. The walls were to be in double-glazing, and the higher they were the more fit they would be for roofings, ridge-and-furrow fashion, as this new plan before the Floral Committee was shown. These roofs were made as flat as they would carry off the wet, but not of much span, and the north side of each ridge was of wood ornamented; but the shade from those parts of the roof was shown not to affect the amount of light that entered the house and reached the plants in the smallest degree; therefore, such a roof could be made at less cost in the first instance, much stronger than the usual run, and a house so roofed could be more easily warmed, and kept warm at less cost than a double-glazed roof. Therefore, these considerations decided me in my choice of roof to the cube, which roof, as I have just said, was to be of two spans running east and west, the south side of the spans to be glass, and the north sides of wood entirely, and as plain as a cat's face—merely painted like the panel of a door.

Then, my calculation was this: If all this were to be done in the present fashion, it would cost much more than I can spare; and if it were to be kept at work in the usual manner I should not be justified in attempting it, for I could not afford to keep up that item in my bill of expenditure. But if I can do as much for £10 as some do with £20, and many more not under £20, it would be foolish not to do it, for it would more than pay, besides the enjoyment of the thing. The annual expense for firing, together with the interest of the cost price of warming, and keeping warm by double glass round the sides, and wood for half the roof would be as ten would be to twenty, or even to thirty by the rail road. And so I have done it all except the cube; but the money for it had to go where it was not then anticipated, and I must do with one side of the cube for another year, just as I have done with it ever since Capt. Hopkins beat me in out-door Graps.

The pit with most mild bottom heat from a common brick flue and glazed earthenware pipes, is now a fact accomplished. But there is one more side to the subject, the bottom side, and of all the things in this world that vociferous refuse keeps bottom heat the longest, and yet no art of man can get it to heat by fermentation like tan or leaves. But once heat it through

and through with a flue under it, and it will keep warm and comfortable for ten days, may be for twenty; but I made a fire once in ten days, since I got it to go, and that has been enough. No one can have plants with less strength of constitution than some of my minimums are endowed with. My diseased plants, as many would call my spotted, blotched, and variegated seedlings, are Oaks and Chestnuts compared with the progeny from the puny stamens, and yet they, together with such Oaks and Chestnuts, are now looking as I like in that pit with mild moist bottom heat from a common flue, and if I keep them free from hurt and harm through this winter, you need not have the slightest doubts against any plants under the sun being put under the same treatment for any winter during a lifetime.

The next account to settle this year, is that which refers to the lovely *Disa grandiflora*, from the top of Table Mountain, behind Cape Town, the "Cape of Storms," of early navigators. The account was not on cross-breeding it, like *Nosegays* this season, but for cross purposes the other way.

Well, I can call Dr. Lindley as a witness to prove to you and the rest of them, that *Disa grandiflora* was grown out of doors in England five and twenty years back. That it, then, astonished us of the old Horticultural Society, that this could be done, and that we prevailed on Dr. Lindley to cause inquiries to be made to teach us how to do the thing as well ourselves. Sir John Herschel was then two years home in London from the observatory at the Cape of Good Hope, where he observed more things than through a telescope, and amongst other things he observed the natural conditions under which *Disa grandiflora* flourished at the Cape, and not only it but other terrestrial Orchids, which are far more difficult to do here than the *Disa*. For the preceding two years Sir John Herschel had grown those very rare ground Orchids out of doors in his garden, Hanover Terrace, Regent's Park, and he exhibited some of them in full bloom before us in Regent Street, on the 16th of October aforesaid. The *Disa* was not then in bloom, but it was growing out of doors then at Hanover Terrace, Regent's Park, and "D." of Deal, was right in suggesting the experiment and predicting the day when *Disa* would require no more than orchard-house protection in winter to cause it to flourish in the open air in England, in company with several kinds of the Cape *Hæmanthi*, and more particularly with *Vallota purpurea* minor and major, and with *Tritonia aurea*. The two latter inhabit the same regions under the same natural conditions as *Disa*. *Vallota* was the only true bulb found by Dr. Burchell growing in boggy peat at the Cape, and *Tritonia aurea* is as true an evergreen as *Vallota* and *Disa*, and just from the same cause from having its roots in marshy ground, "on the margins of pools," the year round.

The day is not far distant when *Disa* will be seen in the centre, with *Vallota* all round it, and both enclosed in a thick, natural-like belt of this *Tritonia*, on the margin of an English amateur's "lake," with a portable glass-case over them in winter and something "geothermal" to keep the water as they like it for the time, and to have their free liberty like British subjects for the rest of their days.

In the same Number of the "Floral Magazine" in which the *Disa* is portrayed, is another plant which is destined to elevate another family of flowers if it will cross, and it looks as if it would. This is a new dwarf and "perfectly hardy" *Mimulus*, of richer colour than any of the plain yellow ones already in cultivation. It was imported from the highlands of Chili by the Messrs. Veitch, with whom it stood out of doors sealess last winter. It must be crossed forthwith with all the best-marked kinds in cultivation, to infuse hardness into them by degrees, and by recrossing with this, which is named *Mimulus cupreus*, till the new strain is as hardy as the Musk *Mimulus*.

D. BEATON.

BLOOMING TACSONIA IGNEA.

I GATHER from an article in your Journal of November 12th, that there is some difficulty in blooming *Tacsonia ignea*. I, therefore, write to inform you that I bloomed this flower in the summer of last year, and was so dissatisfied with its appearance that I flung my whole stock on to the rubbish-heap. The plant was a seedling of three years old grown on the one-shift principle, in a No. 8-pot, and trained round stakes. The main shoots were a great many feet long. I bloomed *Tacsonia mollissima* at the same time, being a seedling of the same age, and grown in the same way. As I had no facilities for growing these flowers in a

border, and there was no probability of their doing any good in pots, I thought it best to get rid of them, as I judged them not worth the time and trouble spent on them, and the space they occupied. Indeed, they were principally raised by way of experiment. The blossom of *Tacsonia ignea* was a bright cinnamon red, and in no respect answering to the "flowing crimson" of the leading seed catalogues. It certainly might not have been true, but considering the price charged for the seeds I can only say that it ought to have been.—ALFRED COPLAND.

FRUIT-STALK OF THE STRAWBERRY ROOTING AND BECOMING A FRUITFUL PLANT.

a Where roots formed.

b Where crown issued.

As you wish for more information about my little Strawberry plant I have made a rough sketch of the fruit-stem from which it was raised.

I had a plant in a pot which fruited well in June, 1860; after the fruit had been taken off I sunk the pot out in the border. One of the fruit-stems had been left on the plant. Towards the end of July I perceived two little roots growing out of the stem just where it thickens at the base of the little fruit-stalks. A small leaf was growing at this part, which is very common with the Sir Harry and other Strawberries. As I am fond of trying experiments in a small way I cut the stem off, and pegged it carefully in a pot with a hair-pin, and pressed the earth tightly about the roots. I then sunk the pot and kept it shaded, and was pleased to see in a short time other roots make their appearance; and, in about a month a small crown, close to the little leaf where I have drawn a line.

After my last communication I placed my little pet (which has been quite a wonder here) out of doors night and day to harden it; in a fortnight after I was surprised to see two large trusses of flowers make their appearance, which I cut off. It has now three large crowns and four smaller ones. I do not remember exactly where the runners grew, but I think just the same as in other plants.

This time last year this plant had one very small crown; in March this year it showed its first blossom truss, and has never been without fruit and bloom the whole of the summer, and would have blossom now if I had allowed it.

The first fruit-stem this year I tried to root, but I kept it too moist, and it damped off after putting down a root about an inch into the earth. Next year, if spared, I hope to have better success.—J. L.

THE GARDENS AND CONSERVATORIES AT DANGSTEIN.

(Continued from page 169.)

LEAVING this division we enter the Palm-house, and at once find ourselves amongst the regal inhabitants of the torrid zone; or, as the immortal Linnaeus has more properly termed them, "The kings of the vegetable creation." To attempt to describe all the rare and valuable objects here collected together would be vain; we will, therefore, only mention a few of them. Conspicuous amongst others are the *Cocos Naia*, and de Babau (*Coccoloba* Palms), the beautiful feathery leaves or fronds of the former reaching nearly to the roof of the building; *Ceroxylon andicola* (the wax Palm); The East Indian Wine Palm (*Caryota*

ures); a noble specimen of the Hemp Palm of Australia (*Corypha australis*); *Elias guineensis* (the Guinea-oil Palm); *Sebal* Blackboreana, one of those mighty Fan Palms of the tropics; *Chlorodendron* Ernesto Augusta; *Sestori* elegans, and *tepigilosa*, the latter in fruit; the beautiful *Livistona Borbonica*; *Calamus rotang*; *Maximiliana regia*; the Date Palm (*Phoenix dactylifera*); the *Raphia taedigera*, from Rio Negro and the alluvial banks of the Amazon; *Scaevola elegans*; *Thrinax argentea*; the rare *Gonoma macrostachya*, and others. Here also is a noble specimen of the *Cycas revoluta*, or Sago Palm, the Screw Pine of China (*Pandanus utilis*); the Indian Rubber (*Ficus elastica*); the branches of which, spreading over an immense space, reach to the roof of the building; the far-famed, and much-eroded deadly *Ucas*, or Poison Tree of Java (*Antiaris toxicaria*); two noble specimens of West Indian Tree Ferns (*Cyathea serra*), *Ficus indica* (the Banyan tree), *Ficus Lecqoldi*, and others. Here also may be seen, growing as it were in its native luxuriance, the Banana (*Musa sapientum*), a fruit so much esteemed by the inhabitants of tropical climes. Their noble appearance and long broad leaves form an agreeable contrast to the Fern-like foliage of the Palms; they are planted out in well-prepared beds of such compost, and when we state that some of the leaves have attained the length of from 12 feet to 14 feet, some idea may be formed of their luxuriant growth; on several of them we noticed some very large bunches of fruit rapidly approaching maturity. On the front stage of this house are placed the smaller specimens of Palms, &c. amongst which we must not forget to notice the *Phœnix edulis*, *Cerulovica palmata*, and the Veg-table Ivory of South Africa (the rare *Stangeria parviflora*), a plant of which was coming into flower; also the equally rare *Agavea sideroxylois*, the Argan oil plant. There are also many species of rare medicinal plants, and others seldom met with in collections. Before leaving this portion of the building we must not omit to notice two noble plants of *Maranta zebra*, the beautiful dark-striped leaves of which measured from 3 feet to 4 feet in length.

But we are now about to enter the north wing, which is filled for the most part with *Orchids*, the larger specimens being placed on raised beds or stands of rockwork in the centre of the house, the sides are planted with different species of Ferns and *Lycopods*, which produce a very natural and agreeable effect. The *Orchids* consist of fine specimens of *Cattleyas*, *Lachas*, *Brassias*, *Cœnidioms*, *Odonoglossums*, *Dendrobiums*, *Bra-savolas*, *Cyrtopodiums*, *Peristeria* clata, and many others: amongst which we observed a fine plant of *Cologyne pandurata*, from Java, the fiddle-shaped flowers of which are of a dull green colour, marked with ribs or blotches of black; a fine specimen of *Cymbidium giganteum* and *sinense*, and *Dendrobium Chrysolæum* are also well worthy of notice; the latter is, indeed, a noble plant, measuring 2½ feet by 3½ feet; it has lately produced eighteen fine spikes of flower. In the centre is a large ton, over which is placed a fine plant of the rare *Nepenthes Hookeri*. Amongst the different varieties of *Orchids* suspended in baskets from the roof is a very fine specimen of *Miltonia spectabilis*, measuring nearly 8 feet in circumference; also good plants of *Gongora cymbiformis*, *Houlletia Broekleaniana*, *Mitonia* (lowest), and others.

But what is it which has so suddenly attracted our attention, and fixed us, as it were, spellbound to the spot? It is a choice collection of the genus *Arceuthobium*, the small delicately striped leaves of which surpass all others in the richness and brilliancy of their colour. Of this interesting and beautiful tribe of plants the *Dangstein* collector can boast of the following varieties:—*Arceuthobium argenteum*, *ergostium pictum*, *Lobbi*, *Lovii*, *Lovii* *viridescens*, *retacens*, *s. taceus aurea*, *corulatus* and *intermedium*, *Vetchi*, *xanthophyllus*, *striatus*, *quercetella*, *Roxburghi*, and *petala*. They are grown in small pots, placed in an open framework in a case 12 feet long by 2 feet broad; a proper amount of heat and moisture is maintained—two points most essential to the well-being of this tribe of terrestrial beauties. The whole of this valuable collection, which numbers over three hundred individual plants, are in luxuriant health, and a high state of perfection; and they certainly reflect very great credit on the skill and ability of Mr. James Vair, the enthusiastic and intelligent gardener at *Dangstein*. We can only add that “to behold is to admire,” and to the lover of plants a view of these alone would amply repay a visit.

In this house may also be seen some fine varieties of rare West Indian and New Zealand filmy Ferns, grown in large shallow pans covered with bell-glasses. Of this very interesting

tribe of Ferns we observed the following:—*Trichomanes anceps*, *pyxidiferum*, *rigidum*, *spicatum*, *crispum*, *Dancofti*, *reniforme*, and others. *Hymenophyllum hirtellum*, *denissum*, and *polyanthos*, a fine plant of the beautiful *Todea pulchella* of New Zealand, the transparent fronds of which measured nearly 2 feet in length; also the rare *Epidopteris peltata* and *Trichomanes trichoides*-m.

Leaving these charming and interesting objects, we pass on to the east wing. Here are grown plants remarkable for fine and variegated foliage. It contains large specimens of *Philodendron pertusum* and *pinnatifidum*, *Pendanus variegatus*, *Theophrasta macrophylla* (coming into fine flower), *Crinaum asiaticum*, *Rhopala corcovadensis* and *De Jonghi*, *Croton variegatum* and *petum*, the Rice-paper plant of China (*Aralia papyrifera*), *Aralia pulchra*, *Gastonia palmata*, *Ficus ferruginea*, *Aralia leptophylla*, *Caraya guianensis*, and others. Also a noble specimen of the true *Dragon's Blood* (*Dracæna draco*). This plant was presented to Lady Dorothy Nevill by Mr. Skinner, who obtained it from the celebrated tree at Oratava in the Island of Tenerife. On the front stage are placed smaller specimens of *Dracænas*, *Marantas*, &c.; also *Saussevieria javanica*, *Hippomanes spinosa*, *Ananassa sativa variegata*, and others of equal beauty and interest. Different sorts of *Fassuolas* and other beautiful climbing plants are trained to the entire roof of the building, the flowers of which, hanging in graceful festoons, produce a very pleasing effect. *Stachyops* and *Acinetas* are suspended in baskets from the roof, many of them were coming into fine flower. A fine plant of *Acinetas Humboldtii* having eight spikes of bloom.

This large building is heated on Hayden's principle of hot water and air combined, and gives great satisfaction. A commodious potting-shed is attached to the building, under which is an immense tank for the reception of rain water, which is so beneficial to the growth of plants.

Bidding adieu to the regal inhabitants of “the tropics,” we pass on to the greenhouse and fernery, a span-roofed building 103 feet long by 32 feet broad, and 16 feet high. We enter the greenhouse which was gay with flowering plants, consisting of *Heaths*, *Epacris*, *Azaleas*, *Pimeleas*, *Eriostemons*, *Indian Rhododendrons*, and other plants used for decorative purposes. Here, also, are some good specimens of *Arucarias excelsa* and *Cunninghami*, *Camphor* and *Tea trees*, *Canellias*, *Oranges*, &c. Of new and rare plants we noticed the beautiful *Cassiope fastigiate*, from the Himalayan Mountains, presented by Mr. Moore, of the Glasnevin Botanic Gardens, Dublin; and amongst other beautiful climbing plants trained to the roof is a fine plant of *Lagerflora rosea*. Some beautiful New Zealand, Madeira, and rare British Ferns occupy a stage at the east end of the house. But we are now approaching the fernery, and here feel inadequate to the task of doing justice to a spot which may not inaptly be described as a “fairly land.” The beds or stands for the Ferns are of an irregular or serpentine form, constructed of large masses of sand-stone rock, as are also the back and end walls. These being covered with Ferns and *Lycopods* give it more the appearance of a natural cavern than a building erected so recently as 1855. The central columns or supports of the house are covered with ragged pieces of rock in which Ferns and *Lycopods* are placed; they have a very pretty effect, and the walks which are of rough gravel harmonise nicely with the whole. Of Ferns there is a rich and varied collection, consisting of *Adiantums*, *Aspleniums*, *Polypodioms*, *Pteris*, *Lastræas*, *Davallias*, and others. Amongst the more costly and valuable, are *Cibotium Schiede*, the graceful fronds of which are from 10 feet to 15 feet in length. A noble specimen of *Cyathea medullaris*, that gigantic tree Fern of New Zealand, the fronds of which have reached to the roof. Large plants of *Alsophila australis*, *ferox*, and *Mequeli*, *Cyathea arborea*, *Angiopteris erecta*, *Marattia elegans* and *ciuctifolia*, *Davallia diffrida* and *auriculata*, *Litobrochia respertilionis*, *Blautium cicutella*, *Lastræa Kunzei*, *Hemitelia horrida*, and others. Also, a good specimen of *Todea Fraseri*, and *Odontosoria tenuifolia*. Some beautiful specimens of *Drynaria coronata* and *orbiculata* are growing on large stems of Oak, around the knotted trunks of which the beautiful little *Cynophlebium repens* may be seen growing. In large pans suspended from the roof are fine plants of *Woodwardia radicans*, *Nephrolepis davallioidea*, *Goniophlebium inaequale*, *latipes*, and *Reinwardti* or *subauriculatum*, the latter suspended over a tank in the centre of the house, its gracefully drooping fronds reaching to the water's edge. Trained to the roof are some beautiful species of *Lygodiums*. In this house also is a good collection of *Selaginellas* and *Lycopods*. Immediately at the back and connected with

the fernery by large glass doors, is Lady Dorothy's museum. Here are collected together objects of curiosity and interest in the vegetable creation. There is also a very good assortment of works on botany and horticulture, to which, thanks to the liberality of Mr. Nevill and her ladyship, the young gardeners at Dangstein have free access. Here, also, is a book for visitors' names, and by its side lies another, titled "Plants in my Garden at Dangstein, 1851." This is an elegantly-bound volume containing a list of the Dangstein collection in 1851, it is beautifully written in illuminated characters by Lady Dorothy. Around the walls are portraits of distinguished personages. There are also some beautiful specimens of anatomised leaves prepared by her ladyship.

Retracing our steps we again pass through the greenhouse, where, before leaving, we notice a small case of *Trichomanes radicans* and *Lycopodium tubridense* and Wilson, planted on sandstone rock, and a continual moisture being maintained they grew luxuriantly.

Near the back of these ranges of plant-houses, is a pit for cultivating Heaths and other plants for greenhouse decoration, behind which in a shady wood is a hardy fernery, which during summer forms an agreeable retreat, and being tastefully arranged has a very pleasing effect.

We now pass Mr. Vair's residence, a neat and prettily-constructed building, situated near the east end of the principal range of plant-houses, and commanding an entire view of the kitchen gardens. At a short distance from this spot an aviary is being erected, which, when completed, will certainly form an additional attraction to "the gardens at Dangstein." From this spot a commanding view of the gardens and principal ranges of houses may be obtained. A broad walk runs from east to west fronting the principal range of plant-houses, and the ground which is formed on terraces, is bounded by a lovely valley which is now being formed into a kitchen garden, although it was originally intended for a pleasure ground.

Taking our route by the eastern side of "the old kitchen garden," we again reach the pleasure grounds, to the left of which is a beautifully shaded wood, which to the lover of rural retirement affords a delightful retreat.

Proceeding onward we again approach the mansion, to the south-west of which is a tastefully-arranged flower garden, joining which is "The Pinetum," containing good specimens of *Arancarias*, *Cupressus*, *Abies*, *Piceas*, &c. Leaving this we enter a spacious avenue of *Cedrus deodars*, which leads to the principal entrance to the mansion, and having almost reached our journey's end, we cannot leave this lovely spot and beautiful scenery without expressing our heartfelt thanks for the rich treat we have received; and, for the benefit of the readers of THE JOURNAL OF HORTICULTURE, we must add that Mr. Nevill and Lady Dorothy, with a truly liberal feeling, have kindly thrown open to the public their gardens and conservatories at any time (Sundays excepted). Free admission being obtained on application to Mr. Vair, to whom let us in justice again state that the greatest credit is due for the excellent order and arrangement of everything connected with the horticultural establishment at Dangstein.

With a fervent hope that long life and happiness may be granted to the noble owners who have devoted so much to the science of botany and gardening, and bestowing one farewell glance on a spot which must ever possess charms for the humble writer of these pages, we reluctantly bid adieu to "The Gardens and Conservatories at Dangstein."—W. G. P. C.

MUSCAT HAMBURGH GRAPE.

My experience with this Grape is, I believe, more against it than you state at page 302 and 406. I planted one of the three-gumma Vines in August, 1858, which had one bunch in 1859, three in 1860, and five in 1861. I have grafted or inched it on four Black Hamburgs, one of which had two bunches in 1860, five in 1861; and another of them had three in 1861. I also grafted it on a St. Peter's which had four bunches in 1861, in all twenty-three bunches, which did not all weigh two pounds when ripe; they set badly, shrank, shrivelled, and ripened very irregularly. I have also grafted two on a White Muscat, and one on a Muscat Muscatine.

I commenced forcing the 10th of December, 1859, and 26th of November, 1860. I believe the very fine bunch of it figured in "The Florist" was grown in a cool greenhouse, and those

mentioned by J. Finlayson in an orchard-house, who, I think, is rather sharp upon you.

I am, therefore inclined to think it may not bear early forcing; and, as I do not intend to begin to force in till the end of January, I shall in some degree be able to judge if that is the cause.

I hope your readers, &c., who grow this Grape will give their experience so that its true character can be known. My viney has a span-roof, 50 feet by 12 feet 6 inches, roots all inside; the soil 2 feet deep, on flags which have a chaub-r under in which passes the flue from a cylindrical boiler, 5 feet by 2 feet, heating two rows of four-inch pipes laid side by side; the roof is double glass, 1½ inch apart.

The temperature here on the 16th of November was 22°, in the night previous; on the 17th, 20°; on the 18th, 14°; on the 19th, 17°; and at 9 A.M., 38°.—J. ECROYD, *Marden, Lancashire.*

LINTON PARK,

THE SEAT OF LADY JULIA CORNWALLIS.

It is at times difficult to account for the taste which placed some of the mansions of our nobility and gentry in positions so ill-suited to the comforts and requirements of its inmates. Some are inconveniently planted in a damp valley, while others are perched on the top of a hill, at once difficult of access, and exposed to winds from every quarter. In so far as gardening is concerned the former is certainly the more advantageous; but there are no medium situations better, alike for a human residence and that of the vegetable world; and fortunately most large towns, as well as the private mansions of our nobility, are often placed on such situations—that is, sufficiently elevated to be out of the fogs and damps which hang over a low position, and not too high to have to endure the bleak cold winds and stormy blasts of a long winter. One of the class whose position is thus happily chosen is Linton Park, the noble seat of Lady Julia Cornwallis, and the "Ladies Cornwallis," which is placed about midway up one of those ridges of hill which divide the county of Kent into two unequal halves, the southern portion being that level district known as the Weald, and the northern, being more undulating, contains great variety of soil, aspect, cultivation, and general features. Linton Park, however, from its commanding position overlooks the greater part of the Weald of Kent (a district famous for its Hops), the view from the mansion extending east, south, and west for twelve or fifteen miles unbroken by any intervening object, and some distant objects of twice the above number of miles are also visible. Still the situation cannot be called an uncomfortably high one; the ground at the back of the house rising quite 100 feet above the top of it, giving it the appearance of snugly resting on the side of a hill near the bottom than the top, set some 100 feet or more above the valley below. The ridge on which it stands extending east and west for several miles in both directions, forming, what is called in homely language, "the backbone of Kent." The country round seems to be mostly orchards and Hop gardens, and being mostly spade cultivation it is needless to say enclosed a high state of management, supporting the idea so often put forth that Kent is the garden of England.

The road to Linton from Maidstone (four miles) is hilly. "Kentish rag" stone appearing in most of the cuttings, through which an excellent turnpike road runs, and the pleasant and romantic village of Loose, with its paper mills and village church nestled in a deep valley, has a pleasing appearance. An aged Yew tree in this churchyard in excellent health has a trunk 33 feet in circumference at the narrowest part between the root-forks and the limbs, and though hollow, in fact a mere shell, it still promises to outlive many generations of worshippers who weekly pass under its shade. Further on we come upon what in former days obtained some celebrity as the head quarters of several thousands of men who for some time were encamped upon it to repel a threatened French invasion. The Cox Heath, however, of those days is now a smiling district of orchards and fields, and dwellings devoted to more peaceful occupations now occupy the site of the bleak waste; and let us hope that a similar assemblage of armed men may be never wanted again.

The entrance to the park, by a neat and commodious lodge, is on this elevated region. The park at this entrance for some distance having more the character of dressed ground, clumps of shrubs and ornamental trees being studdled about. But before descending the hill leading to the mansion the carriage road

enters a noble avenue of Beech and Elm trees, the lower portion being of Elm of two continuous rows on each side; the inner rows being 90 feet apart, and yet at that ample distance their tops have met. This avenue is perfectly straight, and points to

the mansion; but the descent at the lower end nearest the house being so great, the carriage road winds round by one side. The carriage road is on the north side; but another road from an opposite direction also meets at the same place.

The mansion is one of those commodious Grecian structures combining all the advantages of inside comfort, with a pleasing exterior of a light stone colour, which shows to great advantage amidst the mass of foliage by which it is surrounded. The south front presents a facade of 150 feet. The north side, communicating with the offices at the north-eastern corner, is considerably longer. A gravelled terrace 30 feet wide extends along the south front, and, returning at both ends, encloses a large area at both the east and west sides. This terrace is bounded on all sides by an ornamental balustrading, and, it is proper to remark, is overlooked by a balcony above running the whole length of the mansion, which is also on a level with the drawing-room floors and the north entrance, the declivity making about 12 feet difference on the two sides of the house. Still the grounds rapidly descend to the south, and a succession of slopes and landings carry us down to the terrace garden immediately to the south of the house. The descent from the gravelled terrace to this garden being about 28 feet, in four stages, the upper one being a perpendicular wall surmounted by the balustrading alluded to; the other three being slopes requiring respectively ten, nine, and thirteen steps to descend to the basement. The flight of steps, 15 feet wide, descends in front of the centre of the house, the top flight alone diverging right and left, as is usual on such places.

These slopes, which form so important a feature in the place, are partly clothed with Laurel cut to the exact shape of the ground, with Cedars and other symmetrical-growing trees rising up amongst them at regular intervals. A portion, however, on both sides of the steps is of turf; and the whole of the flats or landings, except what is occupied by the steps and their landings, is turf also. The view, *fig. 1*, conveys some idea of how this is done; but the greater portion of the

steps and landings are necessarily concealed by the Laurels. Half-hardy creepers and other ornamental plants are trained against the terrace wall; and a border of Yuccas at the base of this wall is not the least important feature in the place, as we have been told as many as a dozen have been all in flower at one time, and each of them from 8 feet to 10 feet high. It is needless to say this has not been the case the present summer, but may possibly be so next year.

Westward of this terrace garden is the roseary, which will be described hereafter, and with some shrubbery the grounds terminate in this direction; but eastward they extend for a considerable distance, the inclination of the ground being still to the southward, though less steep than immediately in front of the mansion. The most eastern portion of the grounds being the pinctum, where some noble specimens of *Droseras*, *Pinus insignis*, *ponderosa*, *cephalonia*, and other kinds, scarcely to be excelled anywhere, are in excellent health; but other flower gardens, to be described hereafter, form an intervening feature, the basket garden, being one; and a walk which crosses the grounds in a north and south direction, taking in a fountain in its course, and having six distinct flights of steps in its ascent, terminates at the top in a Dutch garden, of which a figure has already appeared in our last Volume, page 101. A conservatory forms one side of this garden, and at the back of this is the kitchen garden, with some vineries and forcing-houses against its north wall; and behind these again the pits and frames, so essential to a garden where flower gardening is so extensively carried on, and where the requirements of a family have to be attended to.

Our engraving (No. 1) is a north-west view of the mansion and terrace, the slopes of the latter being covered with Laurel cut to the same shape, with some Cedars occupying the corners

and other places amongst the cut Laurels, conceal the broad flight of steps in the centre, or nearly so, but the balustrading is shown in places. Perhaps, however, the annexed diagram or section will convey the best idea of the slopes and levels.

It is proper to remark that the banks of cut Laurels here shown, have an opening in the centre for a broad slope of grass on each side of the steps. The slope at the steps is also cut backward in a sort of fancy curve, so that the lowest step is not

Fig. 2.

so forward by several feet as the base of the lowest Laurel-bank. This accounts for so few steps being seen. The ends of these Laurel banks are all cut square, and in a line with each other. The ground at this point taking the character of an inclined

plane leading to the bottom, instead of the slopes and landings, the basement forming the first flower garden, *fig. 2*, being nearly level, is about 160 feet square. The centre bed, an oval, being 90 feet by 68 feet, or exclusive of the grass margin it is 84 feet by 62 feet. A large place to fill entirely with flowering plants. The side beds are 22 feet wide, and the two ovals in perspective.

Below this garden, or to the south of it, the ground falls about 4 feet by another grass slope, and beyond this it inclines still further to the southward, where a ha-ha wall separates it from the park. This second basement is also occupied as a flower garden, but the beds are not so large as those in the upper part, as shown in the figure, but two beds planted as striped borders pointing towards the house were 17 feet wide, the other beds, however, were smaller, and all were in full view from the mansion and terrace above.

Of the planting of the large central bed in the upper garden, Mr. Fish reported very favourably on in the autumn of 1859, and a design showing the manner in which it was done that season, as well as the winter design for colouring it with different materials, and we are told a fresh one is supplied every year, and when we saw it in August nothing could well look better, and at our request, Mr. Robson has given us the following ideas relative to the planting and managing of so large a space, which we give in his own words.

"In planting so large a space as the one in question, two or three objects must be kept in view, that might, in a certain degree, be disregarded in planting a number of smaller beds. First, the whole of the plants used must be as nearly as possible of a uniform height, both in the early part of the season, and at the end of it. Secondly, only such plants are suitable as require little or no attention after planting, for it is difficult even with the greatest care to get amongst such a mass of plants to dress or prune them without doing much harm. Thirdly, only such plants ought to be used as look well all the season. These conditions it will be seen exclude a great number of plants generally esteemed as amongst the most ornamental of the flower garden, and of late years I have restricted the planting of it to the following—*viz.*, Geranium, of the scarlet variety (Tom Thumb); Geranium, variegated; Alyseum variegatum; Lobelia, a strong-growing, pale blue variety, of great endurance; Calceolaria aurea floribunda, and occasionally Verbena pulchella, Purple King, or a plum-coloured variety called Anostis; but this season no Verbenas have been used, and I see no reason to wish for them again, excepting as a change of crop, and of the respective merits of the plants named I have no hesitation in saying that Tom Thumb Geranium, and Alyseum variegatum, are the two most useful, and next to them the Lobelia and Perilla nankinensis ought all to be used. I planted it extensively on the side beds with good effect, and regret not having some of the stringwork of the large bed of it the past season. These four plants I have no hesitation in placing as first on the list of useful ones, and next to these Calceolaria aurea floribunda. As a yellow it is exceeding useful, but it is not such a continuous bloomer as the Lobelia; nevertheless, it ought always to have a place.

"The design of the present year is certainly not the prettiest that has been planted, but as a change was wanted each year, it was adopted, and the plants have done well. The Calceolarias which at one time were the most gay things in the bed, failing first. It is also proper to remark, that in consequence of not having enough plants of Geranium Tom Thumb to plant the outer groundwork and central compartments, the latter were planted with Geranium Tritanthus Rose, which became a little too late for the Alyseum. This may be called the greatest defect in planting. The seedwork of Alyseum kept pace exactly with the Lobelia, which formed the ground to it, and Geranium Tom Thumb was also the same height. If, however, we had had the good fortune to have planted Perilla as a stringwork to separate the central compartments, the effect would have been better, as that plant looked exceedingly well used in a similar way in the two side beds.

"The large side beds, 22 feet wide, were with alternate circles and panels in the centre, and strip a at the outside of Tropaeolum elegans, and Mangles' Variegated Geranium, the stringwork which surrounded the circles being of Perilla, contrasted strongly with everything else, and was much admired; but if figures of the beds be given, the following particulars of the planting will explain in which way that was done:—

"LARGE CENTRAL BED.

- "A. Ten wedge-shaped, and one circular compartment, Geranium Tritanthus Rose.
- "b. Groundwork surrounding the above a light blue Lobelia, of strong growth.
- "c. Twenty circles of Calceolaria aurea floribunda.
- "d. Border of Geranium Tom Thumb surrounding the Calceolaria circles.
- "e. Alyseum variegatum forming an outer edging, and all the inner lines of stringwork also dividing the central compartments, making the serolis on the Lobelia groundwork.

"SIDE BEDS, BOTH ALIKE.

- "f. Twelve circles of Calceolaria aurata multiflora.
- "g. Ten panels or compartment of Horseshoe-leaved Geraniums (scarlet-flowered).
- "h. Stringwork dividing and surrounding the above of Perilla nankinensis.
- "i. Band 2½ feet wide of Geranium Mangles' Variegated.
- "j. Band 3 feet wide of Tropaeolum elegans.
- "k. Outer edging, Alyseum variegatum.

"There were two more tolerably large beds in this garden, but their planting did not present anything remarkable. The next important feature being two broad beds on the second basement, with a glade of grass 12 feet wide between them pointing to the centre of the mansion (the same as the large oval alluded to). These beds were each 17 feet wide, and were planted on the span-roofed principle of the ribbon-border, thus, beginning at one side.

- "1st row, Cerastium tomentosum.
- "2nd, Verbena pulchella
- "3rd, ditto
- "4th, Geranium Brilliant.
- "5th, " Flower of the Day.
- "6th, Perilla nankinensis, and dwarf Dahlia Zeldua, mixed.
- "7th, Chrysanthemum regale, a double yellow-flowering variety; an early and continuous bloomer.
- "8th, ditto ditto.
- "9th, Perilla nankinensis and dwarf purple Dahlia.
- "10th, Geranium Flower of the Day.
- "11th, " Brillante.
- "12th, Verbena pulchella, making with the next row a band of 2½ feet.
- "13th, ditto ditto.
- "14th, Arabis variegata.
- "N.B.—In the mixed row there were three plants of Perilla to one of dwarf Dahlia.

(To be continued.)

SALT AS A MANURE FOR PEACH TREES.

This is a most dangerous stimulant, often deadly, and should not be applied to Peach trees unless the soil is a blowing sand, and then some other means had better be resorted to, to make the soil firm. Salt is injurious to Peach trees, by prolonging their growth, so that in November they are likely to be covered with green leaves and immature shoots. Peach and Nectarine trees like a solid soil. In the case of your correspondent who seems to have a dark, porous, friable soil, if the trees appear to want vigour, he should look in a dressing of rotten manure—say 6 inches deep, and then on a dry day ram the surface of the border with a wooden rammer. After this he should give the surface a slight dressing of manure, and never touch it (except to hoe off the weeds) till next year, when a ramming without stirring the border may be given, and manure laid on the surface as before.

A border for Peach and Nectarine trees should be solid, and never stirred, unless it be poor, so that the roots of the trees require some manure. This annual ramming of the surface of the soil of Peach-tree borders in light, porous soil, should take place in March, a surface dressing of manure then applied, and the border kept clean with the hoe. I need scarce add that no cropping of such borders should be thought of. Their width may be from 6 feet to 8 feet.—PENSICA.

THE CAMELLIA AND ITS CULTURE.—No. 1.

We have nothing in our greenhouses so universally admired as the Camellia. China and Japan have furnished us with many things of surpassing interest and commensurate value in a commercial point of view; but no subject yet introduced, horticulturally speaking, has had that round of success, unless it be those glorious bouquets of corgos, Azaleas, which, as specimens of beauty, are unsurpassed, but as individual blooms are very much inferior and far less serviceable for decorative purposes than the

Camellia. On all great occasions the lady portion of the community, if they had a choice, would say, "Oh! if it is not too great a favour for me to solicit, I would prefer a white Camellia bloom to all the other flowers in your greenhouse. I don't profess to say that it is equal to your fine varieties of *Catleya labiata*, or *Lælia anceps*, or even a single bloom of the lovely *Phalenopsis*; but these are only at the command of those who indulge lavishly, and who have ample means to second that love for the beautiful in Nature which engages my sympathy and admiration, although beyond the powers of my purse to enter in. I have learned therewith to be content with far humbler examples than those referred to, and chief among my favourites are the various tints of the Camellia."

I fully enter into the spirit of this lady's remarks, and although my sympathies and likings are pre-eminently orchidaceous, still I rejoice to cultivate (and who does not?) and watch the progress of a superb collection of this lovely species. I can yet well remember how fascinated I was at seeing a small collection of these in bloom for the first time; and on many occasions since I have watched with curiosity and pleasure the effect produced upon the minds of individuals placed in similar circumstances. There is a love for the beautiful planted in our natures which grows in intensity the more we become familiarised with vegetable physiology. Is it not a remarkable fact, however, that all students who dip deep in any science or art have often their actions misconstrued? Point out to me a first-rate botanist or a first-rate entomologist, or a first-rate in anything, and you will see at once that his assiduity and enthusiasm are set down by the unsuccessful and uninstructed in these matters as a species of paradox and absurdity. I could point out to you a few gardeners who have seen, so to speak, two or even three generations pass away, and yet they are as keen and enthusiastic now in the art as they were when apprentice boys. It is to such gentlemen as these, imbued with the spirit of progress, and ever ready to inculcate from their fertile resources golden ideas into the aspiring juvenile mind that horticulture mainly owes its progress. So far so well. May such a state of things long continue to go on and prosper.

There is nobody, and I say it advisedly, who has a small greenhouse but can have good Camellias. Like all other things, however, the better accommodation at command the better specimens of skill can be produced. The great majority of the well-to-do in this country, and no country upon the face of the earth can boast of so many hives of industry among all classes, cannot afford to have large glass erections; therefore, the difficulty for the gardener, or the man who is expected to have a knowledge of the profession, is proportionately greater, according to the ambition and requirements of his employer. It would be the height of vanity for a first-rate gardener to tell a lady or gentleman that with his or her limited accommodation he or she could have first-rate examples of Grapes along with a miscellaneous collection of plants all huddled together in one house. It is not an uncommon observation for ladies and gentlemen (for we have heard of such both in England and Scotland), who are partly excusable because they have no special knowledge in the carrying out of these matters, to descant upon the time and material that their servant can devote towards the successful cultivation of the Vines and other plants which their greenhouse contains, and yet not attended with that success which they were led to expect when first embarking in the speculation. The error, on close examination, is often detected in the endeavouring to carry out too much with too little appliances. The remedy is obviously apparent in the curtailing the multiplicity of subjects, or adding to the glass erections.

We have no wish to damp the ardour of those who have embarked, or are intending to embark, in such a speculation. We only wish to check exorbitant thirst for variety, for the benefit of both servant and served. But let me tell you honestly that it requires no ordinary vigilance in studying cause and effect, before you can be thoroughly successful with mixed variety, and, doubtless, many of the readers of THE JOURNAL OF HORTICULTURE can echo my sentiments in this respect, and all the more readily appreciate and admire the fertile resources and oftentimes happy conclusions of the gentleman who is more immediately connected with this department.

We intend to discuss the culture of the Camellia under the following heads—Soil, Habit, Temperature, Moisture, Varieties, Propagation, and, lastly, its adaptability for, and treatment amongst mixed collections, as implied in our introductory remarks.

SOIL.—There is no such thing now-a-days as great varieties of compost intermixed to form a harmonious whole, for the well-being of specific subjects. Neither is there any arbitrary colour or shade in the great variety lying on the crust of this earth to warrant us in assuming that that colour only possesses the efficacious occult power of promoting the healthy development of a given species of plants. If there be such a thing as a latent tendency in the mind of the amateur leading in this direction, we would point at once to the varied character of the fields over the length and breadth of this country, each producing, with proper treatment, ample crops of Wheat and Barley in the one instance, and Potatoes and Turnips in the other, to justify our hypothesis. Chemistry has opened our eyes widely in this direction; and the conclusions derived from this analysis are fortified by the actual experiments of practical men and first-rate cultivators who knew how to promote healthy development, contemporary with the earliest students of agricultural chemistry, and know still how to do so without the slightest smack of the theory of the science.

It was a practice, however, not altogether obsolete at this day, for some to put their various composts through a half-inch riddle, so as to have the soil they intended to replot with as comminuted as possible; whereas now, in most cases, that is exactly the soil that is laid at one side to be used only, if at all, for pot culture on rare occasions. We have learned by experience that the atmospheric air in the soil is the most important and subtle component of it all towards maintaining perfect development and mutual reciprocity between the root and the branches. We have learned also that gradual decomposition of extremely nutrient tends greatly to facilitate a healthy power of action, and produces a greater yield in a given space, than allowing such nutrient to be too far decomposed, and its ammonia dispersed before application. Indeed, practical gardeners, unacquainted with chemistry, are at a loss exactly to state how much per centum of success may be attributed to the one, as against the other, when both are introduced so as to act in harmony with their ideas.

The most intelligent and persevering farmers are fully alive to the importance of a thorough aeration of their fields, and they are all setting about industriously to propagate a desire among their fellow men to have their land deep ploughed, "heavily subsoiled," to use their expression, because they have seen and know by results the value and profit of the experiment. They are calculating that by adopting this method they will have so much less per centage of manure to provide, and even some in their enthusiasm declare that there will be little, if any, need of surface draining where this is adopted. In fact, they calculate that no land is in first-rate order unless it has for a depth of 12 inches one-third of that body composed of air.

We are fully satisfied that their views are correct in this respect, and we would submit, if it is necessary, to have one-third of the component parts of land composed of air which requires little, if any, artificial watering to clog up the pores. It is absolutely necessary for the well-being of plants in pots to have at the very least no less of that element. These being our views we make our general selection of composts in accordance with the particular kind we use with success for the Camellia will be given in another chapter.—JAS. ANDERSON, *Meadow Bank, Uddingstone.*

AUTUMN-BLOOMING CYCLAMENS.

WHAT is the name of a variety of Cyclamen which I have, and cannot identify by the description given in any list or catalogue to which I have access? It blooms in September, the flowers are of pale lilac colour, with darker centre, and the leaves do not appear until the flowering is over and the seed-pod formed, which, as in the case of colum is enveloped in the spirally-twisted flower-stalk. I ought to add that the foliage is very handsome, the handsomest of all, and not round like that of colum and persicum. It (the flower) has no scent.—A. C.

[You do not state whether your Cyclamen is in a pot or in the open ground, hardy or not hardy. All the information in one's power should be sent when a plant is inquired about, or a specimen is sent for identification. The way to answer you and many others, however, about these Cyclamens is very simple.

Two kinds of Cyclamens only bloom in this country in the autumn, and no two kinds were ever more confounded the one with the other, and both are perfectly hardy. Yours must be one of them, and is out in the border from year's end to year's

end. The two kinds are quite as different in leaf and looks as a gander is from a turkey cock. You say "the foliage of your Cyclamen is very handsome, the hampsonism of all, and not round like that of *colum persicum*;" and we put the italics to show the difference between the two kinds of autumnal-blooming Cyclamens; the one has the leaves just as round as those of *colum*: therefore that one is not the kind you have; and the question is answered, for it must be the other.

Cyclamen europaeum and Cyclamen neapolitanum are the only two which bloom in the autumn, and europaeum has the leaves more round than any of the persicum race, and nearly quite as much so as those of *colum*: therefore it cannot be your plant. Yours is, undoubtedly, the Cyclamen neapolitanum of old Tenore, and of our best botanists; but it has more names—as autumnale, purpureascens, Poli, and hederifolium, and it is more hederifolium-like than most of them; but there is a very different kind to which the name hederifolium (ivy-leaved) was first given, and that kind blooms in the spring after the persicum, the *colum*, and the Atkinsii are all over; and never does it bloom in the autumn. There are, therefore, in cultivation two kinds called hederifolium, a spring-flowering hederifolium, which is the true kind, and the autumn hederifolium, which is the neapolitanum, which is yours, and which you say is "the handsomest of all" in the leaves. Mr. Wearer, at the College, Winchester, has some rare old stocks of this handsome Cyclamen, and Mr. Beaton, we hear, wants both kinds which are indifferently called hederifolium.]

SHORTT'S PLAN FOR THE PREVENTION OF THE POTATO DISEASE.

I PROMISED to give a few notes on the issue of our trial of this plan, and I now attempt to do so. Before going into our experiment it would be wise to give the letter in full, as read before the Council of the Royal Agricultural Society in February last:—

"As soon as I perceive the leaves of my Potatoes to be tainted, I immediately cover them entirely with earth, leaving the roots high and dry, the ridges being not less than 30 inches apart. The consequence is, that every tuber remains perfectly sound, without rot or blight. I do not pretend to explain the cause of this, which, probably, may arise from the exclusion of atmospheric influence, as well as from the better attention to the effect. I am at present joggling as fine and as healthy Potatoes as I ever grew, whilst a considerable portion of some which were sown only a few feet distant, but not earthed up, I find to be decayed and useless. This mode of treatment is equally applicable to every variety of Potato, and every description of soil. I have tried the experiment in fields as well as in gardens, and with the same invariable result. In 1856, having to plant two acres of Potatoes in a stiff clay soil in Norfolk, I had them ploughed in with a common plough carrying 10 inches to the furrow, leaving the rows 30 inches apart. This was done the third week in March. After the Potatoes were well up, they were lan-shoed, and kept clean until the beginning of June when they were all earthed up with a double-breasted plough; and in the middle of July, 'Howard's Patent Fougus' was used to take a single furrow from between each row, laying the furrow-slice on the top of the rows. In order to test the efficacy of the method, I left some of each variety of the Potatoes uncovered by the earth. On taking the crop up in October, I found every tuber of those which had been covered in the way I have described quite healthy and sound, whilst the half of those which had not been earthed up were diseased and entirely useless, thus showing that the Potatoes only partially covered were affected by the disease, whilst those entirely covered, and, as I said before, lying high and dry, remained untouched.

"Directions.—To the Potatoes, as I have said before, should be planted 30 inches apart from row to row, and 6 inches from set to set in the rows, and be earthed up in the usual way; nothing further is required until the first appearance of the disease in the haulm, when the tops of the Potatoes must be laid on one side of the ridge, and then with a spade take 6 inches in depth of soil from between the ridges and place it on the plants laid down, and so on ridge by ridge until the whole acre is completed, by which means there will be a trench between each row of Potatoes, 6 inches below the tubers, which will be left high, dry, and perfectly sound, all moisture being carried off. As to the expense, which some persons have stated would be greater than the gain, by this plan, I think it right to mention, that the extra labour would be about 2d. per perch, or Devonshire yard. It has been already stated that the plan is equally applicable to the farm as the garden, the only difference is, that one is done by manual labour, and the other by horse labour, which any good ploughman can do with a little practice; the first earthing up with a double-breasted plough, the second with a single-breasted one; laying the furrow, which is taken from between the ridges, on the top of the ridge of Potatoes; hereby there would be a saving of expense, as a man with a plough and pair of horses would be able to do two acres a-day. I hope the plan I have found invariably to answer will be generally tried next season, at least in some of the more favoured parts of the country, in the food of millions!—LEONARD SHORTT, *Gardener to John Mildford, Esq., Coates, Ebor'.*"

On the appearance of this in *Bell's Weekly Messenger*, my employer, Mr. Wm. Sanday, of Holme Pierrepont, was so impressed with the soundness of the idea, that he gave me full instructions to see that it was carried out in its entirety. Accordingly on the Potatoes being planted, April 8th and three

following days, we had them put in 30 inches from row to row, and from 12 inches to 15 inches from set to set (6 inches are too near we think). We always choose a piece of good land on our light soils for Potatoes, and this year it was a piece of very gravelly—there is a gravel-pit in the close. We planted Regents, Flukes, and Cockneys. All went on well till July. In the first week the disease made its appearance on some cold, heavy land in the neighbourhood; but not a symptom on ours till the last week, then those peculiar black spots began to appear on the foliage, and on the 30th we put two men on the job, and as it was something new I went to superintend their start. Then came the question, How are we to do this? and I at once laid down the law, that the tops must all be covered. I insisted on it, that that was the reading of the instructions. I had not the copy of the letter by me, and only remembered its details from my reading it four months previously. I knew he said, "Cover them entirely with earth." This was rather a slow and by no means a nice job, as to cover the tops entirely with earth, the men had to twist them hayrake fashion, on the centre of the ridge, and then put the earth out of the furrow over that. Mr. Sanday was not at home when the men began, but he came home the next day, and on his returning from the close where the men were at work, came to me with a most amused face and said, "However could you think that that was the plan?" I said, "How would you cover them entirely with earth otherwise?" "Oh! it does not mean so," he said, "it means, bend the tops down on one side of the ridge, and put the soil out of the opposite furrow on the top of the ridge, leaving the tops uncovered." "We'll see." I got the paper with the letter in, and we coned it over, and on a first look it does appear that all must be covered up; but afterwards it seems to bear out Mr. Sanday's construction, yet nowhere does it say precisely that any part of the top is uncovered. We at last agreed that part should be done to Mr. Sanday's reading, and part according to mine. So, then, one-half (No. 1), was done by simply bending the tops over the side from the workmen, and putting a spit of earth out of the furrow on the top of the ridge. One-fourth done my way (No. 2), the tops twisted along the top of the ridge and earth put over them, covering them completely. One-fourth (No. 3), left untouched in consequence of the men being taken off harvesting. August came in fine and dry, it arrested the progress of the disease, and on the 14th during a temporary lull in harvest, we decided to take up No. 3, as they were ripe, at least the tops were. On this piece of ground we had at the rate of 130 sacks to the acre or thereabouts, fine, clean, healthy tubers, very few diseased ones, and not many small. On September 20th, afraid lest the weather should come wet and cold, we had the other pieces, Nos. 1 and 2, taken up. No. 1 were not so fine, not so clean and healthy as No. 3, and there were more bad ones and considerably more small ones. The nearest computation that we could come to was about ninety-eight sacks to the acre. The produce of No. 2 grew "small by degrees and beautifully less," for they became smaller in size with more diseased ones; something like seventy-four sacks to the acre.

The experiment then failed, and that which contributed most to the wet weather of the early summer, so that when the soil was put on the ridge, it sealed them up as it were in their moisture, and prevented them benefiting by the dry fine weather of August. Had the weather kept on still wet, as some of us dreaded it would, the experiment might have been successful; but could we only have a recurrence of the same fine weather, and at the same time as this year, we should not need to put in practice any of the thousand and one precautions for the prevention of the disease which are so strongly and lavishly recommended to us.—N. H. POWELL, *Gardener to William Sanday, Esq., Holme Pierrepont, Nottingham.*

IS THE LARCH A DOOMED TREE?

CAN you or any of your subscribers afford me any information as to the probable cause and cure of this terrible blight, with which the Larch, one of the most valuable of all our Scotch woods, has been visited, noticed first in this quarter some six years ago, threatening to fairly exterminate belts of from seven to fourteen years standing? Also, if it be yet known what was the result of the investigations of the talented author of the "Book of the Garden," Mr. McIntosh, to elucidate this mystery?—SCOTTS.

VARIEGATION OF PLANTS.

I HAVE read the articles in your Journal on the variegation of plants, and shall not assert that Mr. Beaton has endangered his valuable heal amongst his sporting Geraniums, but merely state a few facts from my own observations.

About thirty years ago I planted a group of variegated Hollies in a deep, rather rich soil: they were silver-edged, gold-edged, gold-blotched, and silver-blotched. In the course of ten or twelve years the gold and silver-blotched trees became quite green in their foliage, except a few stunted branches low down at the ground. The trees became more luxuriant than those which retained their variegation—so much so that the person now in charge of them cut two of them down because they were overgrowing the others, and because they were but common green Hollies.

Some ten years ago we sowed some beds of Hollies. About 20 square feet of one of the beds were sown with seeds from variegated Hollies; they came up very well, but their cotyledons were all white or a light straw colour, not a green plant amongst them; and in the course of eight or ten days they were all dead, every one of them, and the common green plants, side by side with them, continued to thrive. Perhaps some of your readers have tried the same sowing.

We often observe green branches grow from the old small-leaved variegated Ivy; they are stronger twigs, with larger and better-formed leaves than their neighbours of the variegated kinds. Those are often small and deformed, so are some of the variegated Geraniums. Also, we see twigs produced from variegated Hollies become yellowish-white, not a speck of green to be seen, both twigs and leaves stunted.

Then there is the *Vinca major* with its beautifully gold-pencilled leaves; stimulate the plant, and it will send up twigs with large green leaves without any variegation, and, perhaps, it may be a year before the said leaves become variegated.

If variegation be not a disease it certainly must be admitted that its subjects are dwarfish and stunted.—*LEX, Aberdeenshire.*

GENERALLY USEFUL CULTIVATORS.

As I stated in my last, the reason that gentlemen do not keep in their own hands the land attached to their residences, is, that they cannot find servants to manage it with the garden. When they tried, it was so managed that there was neither pleasure nor profit derived from it; and I have seen so many convincing proofs of this during the past eight years, that to me it is matter of surprise that gentlemen living in rural districts, and taking much interest in the district schools, do not take the most promising boys when they leave school into their service, placing them under the care of some one that will make them, instead of a third or fourth-rate gardener, a good, generally-useful cultivator; for after being in a garden for four or five years, and learning a little by the rule of thumb, young men in size and years, yet only boys in wages, look down upon the generally useful man, and think that to undertake such a situation would be lowering their dignity, and must necessarily bring them a grade or two under the general dignity of "gardener." But, before a man can be a generally useful one, in the fullest acceptation of the term, he must cast aside that false pride, and not attach importance to a name. "Why should I trouble whether I was called the gardener, or the man that does the garden? Names are like naughts in arithmetic—are of no value alone." And let the young gardener get his mind well stored with that knowledge which will be serviceable to the country, and beneficial to himself, and never mind what he is called. Let his employer's satisfaction, and the Saturday night or quarter day, be the test.

I will give one illustration in proof of my position—viz., that there are hundreds, if not thousands, of gentlemen in every county in England, that would give good wages to a competent man that would undertake the management of the garden, land, cows, and any other stock that could be profitably kept. That land can be made profitable to gentlemen as well as to farmers I will try to prove in subsequent papers.

A gentleman that used to visit my late master, one that knew the advantages derived from keeping a cow or two, and making hay for carriage horses, had seventeen acres of excellent meadow land adjoining his residence, his own property, and nearly all could be seen from his drawing-room windows. The lawn, which had a nice, gentle slope from the house, was taken out of a meadow

of about eight acres, and separated from it only by iron rails. There were several ornamental clumps of trees with a belt of Firs and other ornamental trees, from north-east to south-east. The land was let to a near farmer, who mowed it every year, and sold the hay. During the winter young stock was kept on the ground, and served with the roughest and worst hay he had, in dabs about the ground, and from the early part of winter to the latter part of April or May, it more resembled a firm barton than a grass field. Such was the winter view from the drawing-room. Now, this gentleman seeing that his land was being impoverished and made unsightly, and his domestic comforts curtailed, at last spoke to his gardener on the subject of keeping it in his own hands, with a view to profit and improvement, and his taking the management of it with additional help, and an advance of wages. Nothing could appear more reasonable or more advantageous to both master and man.

Now, this man was a common-sense man on things generally, and work was no object to him; and in this matter he exposed his weak points, and his reply was, "That he came there as a gardener, and as a gardener he should remain;" and as he suited the gentleman and lady on other points, the gentleman gave up the idea, and the land is still let to the farmer.

Some time after, when the gardener related the circumstance to me, and I rated him pretty sharply for his folly. His excuse was, that by complying with his master's wish he should destroy his character as a gardener. Since then he has taken another situation, where he milks the cow or cows, and serves the pigs, and is a thoroughly generally useful, doubly valuable to his employer, because he realises the advantages of a country residence. The man is no less a gardener, as he told me some time ago he has been a more successful competitor at the local floral and horticultural shows than in former days when his whole time was devoted to gardening. In his own words, he felt he is "a better man, would fetch a higher price in the market, and always saleable."

Now, all those young gardeners that are a drag in the market, or wasting their time in a nursery, could each one stand in the same position as the man I have just mentioned. First get the will or desire, then add determination to it, and in a very short time they will find they are men sought after. Doubtless, some of the readers of THE JOURNAL OF HORTICULTURE desirous of improving their circumstances, may very justly say, "How can I do it? I am willing to learn and obey, but who will teach me?" In gardening, with perseverance mentally and physically, I can soon make myself acquainted with all the details of the art. There are full instructions of work to be done in the week coming; also, full instructions of what was or should have been done in the week past. Still if the neglected portions are carried out the week following, it will be no disgrace to be only a week behind such men as Mr. Fish. Then, again, if we want to make a dazzling show (and who is there that does not?) and to make it last as long as possible, we have only to consult Mr. Beaton's weekly papers to inspire us with a spirit that will work wonders. But, about cows, pigs, and sheep, is there really anything to learn, or anything worth learning? Most certainly there is, and everything connected with that department wants to be as well understood and as properly attended to as the various plants in the greenhouse. And for the benefit of those who may be desirous of learning something on that head, perhaps a few remarks bearing upon the subject, as a kind of compromise between the work to be done, and the work done, may not be unacceptable to the general readers, providing it is brief. But having exceeded all bounds in this disjointed ramble, I will leave the matter-of-fact till next paper.—*THE DOCTOR'S BOY.*

CONSTRUCTING A PIT OF TURVES.

In compliance with what is stated at page 459 of your last Volume I send the following statement:—

Narrow and Haresfoot Grass having gained nearly the sole possession of many parts of my lawn, I decided to lay down fresh turf. As before stated, the surface of my garden is uneven, and that part the most so, of the least use, being 5 feet or 6 feet below the surrounding ground (except the open end), and of an oblong horseshoe shape, sloped on the sides and one end from top to bottom. I decided to make a pit there, and use the old turf for the walls, as an experiment: therefore I made a pit 6 feet by 12 feet, 7 feet deep on the front and 9 feet at the back,

and covered with one light of Hartley's rough glass. This pit was made in the autumn of 1859.

The following year, being obliged to take up more turf, I made an addition at right angles with the other, such addition being 27 feet long, and as wide and deep as the other part, and covered in the like manner by a light 21 feet long, which touches the other; the square in the corner being covered in a somewhat dome-shape with the like sort of glass.

The pit is 2 feet 6 inches deep in the ground on the front and 7 feet at the back. To the level of the ground is a brick wall, and above the ground all is made of turf. The turf wall is covered with zinc all round, and on the fronts spouts are formed of the zinc, from which a pipe at each end runs through the turf wall into zinc tubs inside to hold water for the plants, and a provision is made for the escape of waste water into the garden drain.

The situation of my garden is rocky, and on the slope of rather hilly ground, running westwards from the back, consequently in the summer parts are rather too dry, and in a wet season there is a great drainage from the higher ground to my garden. To provide for these difficulties I made a border inside the pit, puddled it with clay on the bottom, and 2 feet deep at the back. On the front I put quarries, set in the clay, sunk 10 inches below the surface of the floor, and then cemented the whole border. The quarries I had made 7 inches wide, 14 inches deep, and 1½ inch thick. So far all seem to answer. The part first built drains to the south and the other east inside and outside.

The lights are fastened together, and kept in their places by upright pieces of wood (to which they are screwed) let in, and resting against the turf, and into these props are fixed, with their feet against the walls at the ends, and one near the corner.

There are two openings, each 9 inches by 14 inches, and 6 inches above the ground; two pivot panes in the dome-shaped light; twenty-nine drain-pipes 4 inches wide and 12 inches long, some placed singly, some three together, and others five together, chiefly on the back, and just above the ground; and in other parts there are eighteen one-inch drain-pipes, all in the turf, with zinc caps to all for the winter, and perforated ones for the summer; also an opening at the bottom of each door for ventilation.

Last winter there were planted in the borders a *Lapageria rosea*, three *Camellias*, *Lilium giganteum*, some *Clematises*, *Geraniums*, *Chorozema ilicifolia*, *Adam* and *Isabella Grey Roses*, seventeen of the *Elatan* and *Sikkim Rhododendrons*, &c., besides some *Tropaeolums* and *Alstromerias*, &c., which were plunged. In pots, not in the borders, were two *Deutzia gracilis* and thirteen *Japan* and other *Lilies*.

All the pipes were open up to Christmas-day morning, when I went into the pit about eight A.M., and found the leaves of the plants hanging down, and the soil in the border rather hard. That morning I stopped the openings, and covered the lights with single mats, which remained on about a month. The plants gradually recovered, and I found nothing injured but some of the *Geraniums*, and I lost the *Chorozema*—nothing more. The *Camellias* flowered afterwards. The thermometer never indicated more than five degrees of frost in the pit.

The plants do very well, except so far as some of them have been injured by having their leaves eaten. What does the damage I cannot make out. I have found spiders and very small flies on the border. I attribute the injury to my neglect in not smoking the pit in spring, as after it was once done the damage was less, and when repeated little more injury was to be observed.—I. G.

HERBACEOUS BORDER IN THE GARDEN

OF THE WARDEN OF WINCHESTER COLLEGE.

You wished to have a list of the plants upon the wall and in the little mixed border which runs alongside of our terrace walk. You have already had all the particulars of this border, which are given in the ninth volume, pages 315 and 346, of your excellent Journal. It is true some changes have taken place in this border since then; but for anything that I may omit here, reference must be made to that volume.

I will begin by giving the names of the shrubs upon the wall. The following is a list of the live and the dead after the severe winter of last winter.

Paliurus aculeatus.—Not injured.

Jasminum officinale.—Much cut up, but has recovered.

J. nudiflorum.—Blossom all killed, tree not hurt. *J. revolutum*.

—Killed entirely.

Lycium europæum.—Not hurt.

Garrya elliptica.—Not injured. A fine plant.

Edwardsia grandiflora.—A very large, fine, old plant. Killed

nearly to the ground, but is putting up shoots again very strongly.

Cydonia japonica.—A fine plant. Some of its branches were

killed. *C. japonica alba*.—The same.

Spiræa Lindleyana.—A fine plant. Flowered very finely this year, not hurt.

Forsythia viridissima.—A fine plant. Its blossom killed; not much hurt.

Olea europæa.—A fine plant. Killed entirely.

Caprifolium gratum.—Not hurt. *C. flexuosum*.—A fine old plant. Killed entirely.

Robinia hispida.—Not hurt.

Passiflora corulea.—Killed.

Clematis azurea grandiflora.—Not much hurt. *C. montana*.

—Not much hurt. *C. bicolor*.—Killed.

Pittospermum tobira.—Killed.

Daphne Dauphini.—A fine old plant. Killed.

Aloysia citrodora.—A very old plant, which is cut or dies down to the ground every year, shot up as vigorous as ever.

Ceanothus azureus.—Dead.

Siphocampylus bicolor.—A very old plant, put up as well as ever.

Punica granatum.—Does not appear to be injured at all.

Chimonanthus fragrans.—All its blossoms and many branches killed.

Deutzia scabra.—Not hurt.

Weigela rosea.—Not much hurt.

Arundinaria falcata.—Very much injured, but is progressing fairly.

Escallonia rubra.—Killed. *E. macrantha*.—Killed.

Buddleia Lindleyana.—Very much injured.

Colletia horrida.—Not hurt.

Veronica Lindleyana.—Killed. *V. speciosa*.—Killed.

Pæonia Moutan.—A fine old plant. Much injured.

Habrothamnus fascicularis.—Killed to the ground. Has put up again very strongly.

Phorium tenax.—Very much injured, but is putting up very strongly again.

Wistaria sinensis.—A remarkably fine plant. Nearly the whole of its blossoms, and its spurs too, were killed; but it appears to be quite recovered again, and produced abundance of bloom in the summer.

Three fine old *Myrtles* had their branches very much injured, but they have put out again very strongly indeed this season.

About *Roses* we have not anything in particular to notice.

Rosa, not at all injured. *Braiceata*, a very old plant, killed.

La Marque, not much hurt. *Jaune Desprez*, killed. *White Moss* not injured. *Maria Leonora*, killed. *Banksia*, very much

injured. *Devoniensis*, killed to the ground, but has put up again and flowered well.

The *Fuchsias Ricartonii*, *virgata*, *multiflora*, *gracilis*, *Youngii*, *grandiflora*, and *globosa* have all been here for the last twenty-seven or twenty-eight years, and are all cut down to the ground every year with the exception of *Ricartonii*. Sometimes some of the shoots of this pass over the winter uninjured; not that it is needful, for they put up so very strongly every year from the ground as to reach the top of the wall.

The following is a list of the plants we had occasion to plant to cover the wall, owing to the loss occasioned by the winter:—*Maurandya Barclayana*, *Lophospermum scandens*, *Cobæa scandens*, *Tropæolum Lobbianum*, *T. carniense*, with several large and tall old *Pelargoniums*, which flowered well and reached half way up the wall, finishing with about a dozen sorts of *Chrysanthemums*. I have just planted also two very strong plants of the *Virginian Poke*, *Phytolacca decandra*, at the foot of the wall to flower and fruit early, its fruit being so very ornamental and showy.

A list of the hardy herbaceous plants that form the back row:—

Spiræa ulmaria variegata, *lobata*, and *japonica*; *Ranunculus repens pleno*, and *aconitifolia pleno* (this delights to be in a shady place); *Polemonium corolium grandiflorum*; *Potentilla McNairiana*, and *Garnieriana*; *Rudbeckia purpurea*, and *hirta*; *Geranium sylvaticum*, *ibericum*, *rheum*, and *striatum*; *Veronica verticilla*, *candida*, *laciniata*, and *elegantis*; *Phlox speciosissima*

rubrum, Riversi, Radetzki, and Rendatler; Anemone japonica; Aster multiflorus; Melittis grandiflora; Melissa grandiflora; Dorianum austriacum; Erigeron philadelphicum; Dielytra spectabilis (two plants); Achillea rosea, pharmanica pleno, and spectatiorum; Monarda didyma; Nepeta violacea; Campanula glomerata autumnalis, azurea, and speciosa; Solidago viminea; Dianthus Garnierianus; Chrysocoma lino-gris; Dracocephalum virginicum.

List of plants forming the front row:—

Scilla peruviana, and præcox; Smilacina bifolia; Pulmonaria virginica, officinalis, and angustifolia; Polemonium reptans; Aster ranosus; Geranium sanguineum, and lanceolense; Geum chilense; Iris pumila; Pancretium illyricum; Narcissus bulbocodium; Erythronium dens-canis; Eranthis hycemalis; Omphalodes verna; Betonica grandiflora; Prunella pensylvanica; Silene Schafta; Viola montana, and calcarea; Arabis grandiflora or eucassica, and caucasica var. variegata; Aubrietia purpurea; Orobus vernus; Anemone sylvatica; Campanula carpatia, carpatia alba, and pumila; Potentilla Tonguisi; Sedum oppositifolium; Trollius europæus; Lithospermum purpureo-ceruleum; Corydalis bulbosa; Phlox Nelsoni, subulata, and procumbens; Pentstemon procerus; Radiola rosea; Achillea tomentosa; Alyssum saxatile; Narcissus minor; Primula Auricula var. hortense, and vulgaris var. double lilac and double white finish the list of the front row at the present time.

We used to have the Crocus and Snowdrop, a few bunches of each, in the last-mentioned row of permanent plants; but now we have taken about 3 inches off the grass verge to make room for a row of bunches of the Crocus, doing away with the Snowdrop altogether from this border, and introducing the Crocus in three colours—white, blue, and yellow, the whole length, which we think will look better and not interfere with anything else. These most likely may remain for some years without being disturbed. Every bunch in the border stands 3 feet apart from centre to centre of each bunch, and the bunches stand exactly alternately with each other—that is, the back is in line 1½ foot from the foot of the wall, and the second row stands in front of the line at 2½ feet from the wall. The back row requires sixty-six plants to complete it at 3 feet apart, and the front row requires sixty-eight plants to fill it, and sixty-six bunches of Crocuses to finish with.

The Crocuses are not labelled, as every one knows it is a Crocus when it is in bloom, and I know whereabouts they are in the border when they have died down, so as not to disturb them at any time or when in the act of planting any other plant; but every one of the other two rows of plants is labelled, and a very nice finish it gives to the appearance of the border during the winter and spring months.

As soon as the leaves are all off all dead flower-stems will be cut and tied up in bundles for other uses, and the border made clean and tidy; and then a few wheelbarrowfuls of leaf mould, old rotten manure, or both, will be broken up and to be put up round the collars and over the crowns of the Fuchsias, Myrtles, &c.—in fact, nearly every plant upon the wall will come in for a share of this top-dressing; after which, when severe weather sets in, the tied-up flower-stems, matting, &c., will be used for protection of the Myrtle, &c.

I forgot the Tigridia-bed which is in the centre of this border. This is always well protected in severe weather.

In this way the border remains until fine and favourable weather in the following March, when the border is carefully dressed off, and any plants that may appear to be too spreading are taken away as the work goes on, and the identical spot to receive it again is thoroughly worked up with a spadeful of leaf mould, old rotten manure, or both mixed together, is added, as I always have my wheelbarrow at my heel with this kind of material in it when I am dressing off the flower-beds or borders.

There are a great number of these hardy herbaceous plants that are all the better for being taken up every year—indeed they cannot be kept in good order without being so cared for; whilst many others of compact and close habits will grow on and do well for several years without being disturbed. Such plants in general do not like to have their roots touched, but would rather have a spadeful of top-dressing round their crowns—in fact, many a choice plant is entirely lost through the borders being handled by careless and inexperienced persons.

In planting out an ornamental mixed border the same kind of plant may be used to much advantage, which is the case in our little favourite border. There two Dielytras, two Phlox speciosissimum rubrum, two Nepeta violaceas, four bunches of

the Anemone japonica, and so on in several instances. This depends upon how much we may like this or that plant. We do just the same in planting a circle or any other shaped bed. We place our plants to correspond and match with each other, varying the colour and kind as much as possible, and always placing the plants in alternate rows.

In our little favourite border at bedding-out time we make a point of using our largest plants of whatever kinds we may think well to use, so as to have the bed as full as we can from the first and to have early bloom. For instance, we use up the old plants of Tom Thumbs and other kinds that were lifted out of the borders the year before. For three or five years we only used two kinds of plants in this border, which were Tom Thumbs in the front row and Colestina ageratoides in the back row; only where the Crocuses, Snowdrops, and one or two others stood in the front row, some other kind of summer plant was set in carefully by their side with a trowel.

Last year we used in the front row Tom Thumb and Variegated Alyssum the whole length, and in the back row we plant every sixth station with Brompton Stock. These were turned out of pots when the border was dressed off in March; then at bedding-out time finished with Colestina ageratoides, compactum, Cerise Unique and Flower of the Day Pelargoniums, using all good large plants; and I believe few mixed borders could look better than this has this summer.

There are a few sorts of annuals sold themselves about in this border—such as Silene pendula, S. armeria, Adonis autumnalis, Hibiscus africanus, Nigella damascena, Chryseis californica, and the Myosotis alpestris. This once occupied two spots in the front row of permanent plants. Though discarded from these two spots, it still is allowed some small space or other, or near to Narcissus bulbocodium, or the Erythronium dens-canis, or Pancretium illyricum, or Scilla præcox. Either this Myosotis, or some of the before-mentioned annuals, are allowed a little space to flower near to any of the permanent plants that may flower and go off early—the Pulmonaria virginica, the Iris pumila, the Omphalodes verna, and some others; but these self-sown plants are not allowed to stifle up and destroy the permanent plant. Sometimes these little plants have to be lifted with a trowel to the right places where they are to flower; but if they should come up in the right place so much the better.

One of this border's greatest weeds is a very rare Grass—Digitaria sanguinalis. This I sowed some twenty-five or twenty-six years ago. Like most things it likes good ground to live upon, and if allowed would be very troublesome.—T. WEAVER, Gardener to the Warden of Winchester College.

MAIZE AND TOBACCO.

THE Indian Corn looked over the fence,
And what do you think he said?
A field of Tobacco, just ready to bloom,
And stretching in lordly pride.

To his broad-leaved neighbour at once he called,
In accents loud and clear,

"I thought you belonged to a summer climate;
Pr'y, what are you doing here?"

So then, with a haughty air, replied
That plant of power and pelf,
"You are pleased to ask of my business, sir—
What do you do, yourself?"

"I feed the mule, and blood, and bone,
That make our farmers strong,
And furnish bread for the fit the eyes
That round their tables throng."

"I move in a somewhat loftier sphere,"
The foreign guest rejoined,

"As the chosen friend and companion dear
Of men of wealth and mind.

"I'm the chief delight of the gay young spark;
O'er the wise my sway I hold;
I lurk in the book-worm student's cell—
In the dowager's box of gold.

"Thousands of hands at my hiding work;
Millions of coin I raise"—
He ceased to speak, and in angry mood
Responded the tasselled Maize:

"You're in secret league with dyspeptic ill—
A merciless traitor band;
With clouds of smoke you pollute the air,
With floods of sweat labour sore;

"You tax the needy labourer sore;
You quicken the drunkard's thirst;
You exhaust the soil—and I wish you'd go
To the place whence you came at first."

THE NEW CONIFERS OF JAPAN.

PL. A FIRMA. Siebold.—THE JAPAN SILVER FIR.

This is one of the new Conifers discovered by Mr. John G. Veitch in Japan, and introduced by him in the early part of the present year. Our figure was drawn by Mr. Fitch, the eminent botanical artist, from specimens of the branches and cones sent home by Mr. Veitch, and which were placed at our disposal by Mr. Veitch, of Chelsea.

The tree attains a great height, and in habit of growth resembles the common Silver Fir. Its branches are produced in regular whorls, and extend in a flat horizontal direction. The leaves are in two rows, very thickly set on the shoots, an inch long, flat, and blunt-pointed. The cones are cylindrical, from 3 inches to 4 inches long, and rather over an inch broad. Scales broad, wedge-shaped at the base, rounded on the margin, and slightly crenulated, deciduous. Seeds triangular, and soft, with a broad wing.

Mr. Gordon, in his excellent work *The Pinetum*, says:—"According to Dr. Siebold, it is found on the Japan Islands of Nippon and Jezo, and is frequent in the provinces of Mutsu and Dewa, at an elevation of 2000 or 3000 feet. The Japanese distinguish different varieties under the names of 'To-Momi,' from the north of China, and the 'Jezo-Momi,' or the 'Nire-Momi' of Japan; this last is distinguished by its leaves sloping more towards the ends of the branches, and by the cones being much shorter. They also distinguish a kind with the ends of the leaves slightly divided (bifid); but such variations appear to be produced by elevation, climate, and soil, and are, as well as Dr. Siebold's *Abies homolepis*, nothing but the species altered by such circumstances."

There is no doubt but that this tree will prove perfectly hardy, as all the other Conifers are that have recently been introduced; and, although it may not possess so distinct a character, nor exhibit so much novelty in its outline as some of the new introductions, yet it will be a useful acquisition to our collections.

CHEAP FUMIGATOR.

I SEND you a description of an efficient fumigator that I have had made, which, from its cheapness, I think deserves to be called a "fumigator for the million."

Procure from a grocer an empty tin canister which may have contained mustard, snuff, clove, or some such production. The cost will be from 1s. to 5s., according to the size or quality, holding from a pint to a quart; get a hole punched in the top and bottom of from three-eighths of an inch to three-quarters of an inch in diameter, and a tin tube about 3 inches in length soldered in each end. The one in the lid should increase a little in diameter from the lid, so as to admit of a pair of common kitchen bellows, being attached to it and tied round with a little rag to prevent the escape of smoke when in use. Then have made a cylinder of perforated zinc about an inch less in length, and an inch to an inch-and-a-half less in diameter than the tin case: this must have at each end a collar of tin or perforated zinc extending to the side of the case as to keep it in the centre when placed in the case; it must, also, be kept about half-an-inch from the bottom by a bit of tin soldered here and there in the tin case, or some such contrivance, as otherwise

the inner cylinder of perforated zinc slipping to the bottom of the tin case would stop up the hole by which the smoke is to find an exit.

To use it fasten the lid by its tin tube securely to a pair of bellows, tying round the insertion of the bellows into the tube a little damp rag, or some such thing, to prevent the escape of smoke. Put into the perforated zinc cylinder the quantity of tobacco likely to be required, light it and give two or three puffs with the bellows before placing it in the tin case. Having inserted the cylinder containing the lighted tobacco in the case, put the lid on with the bellows attached and throw over the case a damp cloth to prevent any escape of smoke at the lid. The tube at the end of the case may then be inserted in any frame or house requiring to be fumigated, and an effect produced sufficient to settle any quantity of insects.

I have, myself, two such fumigators, one made of a tin case, holding about a pint: the other holding a quart. The smaller cylinder will hold about an ounce of tobacco, and the larger one any quantity up to half-a-pound. In using the larger cylinder I find it advantageous to insert the smaller one within

it as it helps to keep the tobacco in its place in course of combustion.

The whole apparatus costs from *Gd.* to *1s.*, according to the size used; and, with the exception of the soldering of the tubes, any one with a little ingenuity may make it for themselves, purchasing the perforated zinc, which costs about *Gd.* per square foot, and using fine copper wire to fasten the side and ends of the cylinder.—COUNTRY CURATE.

GARDEN UTENSILS.

At the Agricultural Institute of Hohenheim, a new method of watering plants and gardens was brought into notice, and which, in German, is called, *Schnelgiesser*; in Flemish, *Schnelgieter*; and in French, *Arrosoir a la minute* (all three terms signifying, literally, *quick waterer*). *Fig. 1* shows this invention with the mode of applying it. It consists of a wooden tub, bound by hoops of iron, furnished at the top with iron handles, and in front with two stout leather straps, by which it is suspended from the back of the workman. At the bottom of the tub is a copper socket, to which a gutta percha or India-rubber pipe is attached, and at that part of this pipe, which may be conveniently held by the hand, there is a small turn-cock, and beyond this a spout and rose, the latter having the holes below. The tub contains as much water as the workman can carry, and when it is empty it is not taken off his back, but filled at the pump by a second person. The turn-cock enables the operator to stop or discharge the water at pleasure. By this contrivance a great saving of time and labour is effected.

Fig. 2 represents a new pot constructed to prevent worm-eating at the hole in the bottom. In some gardens, where the earth is rich, the earth-worms are very troublesome, especially when the ground is damp. In these localities the worms crawl into the pots by means of the hole at the bottom, and if they commit little injury in the open ground, they are not so harmless among the roots confined in a pot. In order to obviate the evil arising from their intrusion, the new form of pot represented at *fig. 2*, has been invented by M. Ghyselin, potter, at Brussels. The bottom is distinguished by having three feet, which are only prolongations of the pot. The bottom is thus raised above the ground, and the worms are thereby prevented from entering at the hole. This pot has also the advantage of facilitating the circulation of air, and preventing the stagnation of water.

Among the useful horticultural contrivances, may be noticed the iron trellis, represented at *fig. 3*, which combines solidity, elegance, and lightness—qualities never found together in wooden trellises. The iron trellis, too, preserves all the forms or shapes which are given to it, and one may thus train plants in all the varied styles which are otherwise applicable. The form which is used has a circular head, like a parasol, consisting of four wires, which are bent and sustained in their position by three circles or hoops, the undermost considerably stouter than the others. The

stem is supported at the base by three prongs, which are made so as to admit of being fixed in the ground or in a pot. This form, when made from 3 feet to 4 feet high, produces a very good effect, when used to support such a plant as *Calystegia pubescens*, which looks remarkably well trained to this form of trellis. This same form may also be used in training climbing Roses, in pots or in the open ground; their branches being led over the arches so as to cover the whole, present a mass of flowers in the summer time.

HYBRIDISING MANGLES' SILVER-BEDDING GERANIUM.

INSTANCES OF VARIATION—SUPERFETATION.

THANKS to Mr. Anderson for the remarks on the peculiar state of the atmosphere. Such was the actual state of it when I succeeded in fertilising two flowers, one each on two distinct plants of the above; and although I tried many at the same time, only two were effectual, and those two, thanks to Mr. Beaton for the knowledge of the effects of the short seasons, were fertilised purposely with the two short stamens of a Golden Chain Geranium, and they perfected four seed-vessels each.

I sowed one lot, and they vegetated; but though they developed the seed-leaves, they could go no further. They were pure white and yellow without a particle of green. They stood from ten to fourteen days, and then one after another bowed their heads, and in a few hours became decayed vegetable matter, verifying Mr. Beaton's experience.

I undertook the experiment because it was stated in THE JOURNAL OF HORTICULTURE, in notices to correspondents, that it would not cross with any Geranium in cultivation. I tried many times after up to the end of the season, but without success: therefore I fully endorse Mr. Anderson's views, that cross-breeding is an open field, and it is very difficult to define where we may or may not go.

I shall not contend with "NICKERBOOR," or any one else, whether variation be disease or not; my own experience would give the vote to Mr. Beaton's theory that it is all in the pollen. In fact, I feel almost justified in saying I could reduce it to a positive law, but it would require experience under different conditions of soil and circumstances to fully bear me out.

I can begot variation at will, either white or yellow, under my present circumstances, to an indefinite extent. The grand point is not to overdo it, or no man on earth can grow them.

While I am upon the subject, I may observe that Mr. Beaton asked the question, a few weeks back, whether variation increased in intensity in proportion to the time it lay dormant, when the proper conditions for its development brought it forth. Now, as he was the raiser of Henderson, can he say whether it showed any signs to variegate in the seed-leaf? If so, he has the opportunity to establish his doctrine, for it has variegated with me, and is one of the purest of the white ones, and I believe, with its white leaves and white flowers, will be a very desirable edging plant, as its rampant growth is very much curtailed.

Query. Who dare attempt to say how many times it had been repropagated before it showed the variegation?

I have also Muscar Martin variegated. Who is his progenitor? I have also a Bramble beautifully variegated, produced exactly as Mr. Beaton described it might be. It was not done intentionally, but it came up where it was not wanted, so its head was pulled off. It came again and was beheaded again, and this was repeated several times. At last the variegated one came, and so it had permission to live. This was done before Mr. Beaton wrote about it, but I thought it worth a passing notice.

Surprise was also expressed in THE JOURNAL OF HORTICULTURE, a time back, at a Carnation two years old and 3 inches high, but I have one two years old, perfectly healthy and branching, only 1 inch high.

I also produced a cross between the Alpine and the British Queen Strawberries. It never attained above 4 inches high, flowering most profusely, but was perfectly barren, and after growing it in various ways three seasons, I kicked it out. May there not be something analogous in these two cases to the short stamens of the Geraniums?

I have a plant of *Pteris edulis* that threw up one frond variegated, but it was barren. I have also a seedling plant of the common Bracken (*Pteris aquilina*) that grows pure white fronds, the quintessence of loveliness, but they are very fragile in the sun. I have no shade to try it in. I thought if it produced

opres next year, perhaps some of the seedlings might come the ordinary variegation.

I find it had practice to sow any choice crossed seed in the autumn. I had from two to three score of very singularly marked Geraniums, many of them tricoloured, yellow, green, and red, in which the green formed so small a part, that after they had not six, seven, and eight leaves in the warm weather they have not been able to hold up against the dark days of November.

I have not convenience to carry out experiments as I should like, yet I do not despair of being able to produce for the gratification of Mr. Robson, some day, Mr. Mangles in a gold-laced coat.

I fancy I have a case of superfetation. Perhaps Mr. Benton would think otherwise, but it was as follows. I had a nicely marked Geranium seedling with good flower and truss, but rampant in habit. I grew it in the conservatory last year, and I fertilised one flower with the pollen of British Flag and Punch, just for experiment. It ripened four seed-vessels—one missing, notwithstanding the abundance of pollen. I sowed each seed-vessel without dividing it. The seedlings came up, and in due time I divided them round a six-inch pot to winter; in the spring they were divided, and planted in the shrubbery with a particular mark. No two of them were alike either in flowers or leaves. One was a model of Punch, another was a model of British Flag, but with larger flowers. I marked it *Grandiflora*. Two were a mixed middle betwixt the three, and the fourth having broken a most beautiful golden variegated shoot with a shade more of the Buttercup in it than Golden Chain, his head was immediately cut off before he opened a flower. This appears to my mind an evidence that superfetation is quite possible.

I have a very nice seedling, very dwarf, and very free flowering, having plain foliage, with a shade more crimson in it than Christine, and in size smaller in the flower, and a third smaller in its growth.—Wm. Smith, *Gardener, York.*

IS VARIEGATION A DISEASE?

By all means let us have things called by their proper names. We are, everybody knows, already running riot with our interpretation of the words of the English language in its etymological sense. Indeed, there is little wonder that foreigners are so perplexed at, and declaim so vigorously against, its peculiar construction and diverse application. Let a few more papers be written to the effect that variegation in vegetable physiology is the consequence of disease—*peccata* as some would have it disease proper, and possibly the very next edition of Walker's Dictionary may have them set down as synonymous terms. Fortunately there is a growing desire in the best conducted literature of the day to discontinue aberrant allegorical construction. There are instances on record of seemingly far less moment than the one in question where the creation of a novel term has called forth a considerable amount of criticism, and lately either been accepted or ignored; among which we might mention Lord John Russell's celebrated phrase in criticising the wording of a certain bill—"Conspicuous for its absence;" and also the adoption of the word *telegram* in lieu of telegraphic dispatch. The latter of these instances, as will still be fresh in the recollection of many of your readers, created a very animated controversy between the chief members of the rival Universities, not to speak of other luminaries of learning. All the Greek dictionaries were dissected in order to establish pro and con their respective creeds of derivation, and now it is one of the commonplace of conversation in everyday life, doubtless all the more readily adopted for its brevity.

That, of course, was simply a question of derivation; but this involves a far more intricate question, more especially if we concede that variegation is the consequence of disease either in root, stem, or organs of reproduction, and something not quite so intricate if we dispute that is disease proper. These, apparently, are the two cardinal points at issue, and all practical men must know either less or more concerning them.

We have no invincible demonstration to convince us that variegation in its many forms is the consequence of disease in the physiological systems of the plants from which it springs, whether that variegation was the result of cross-breeding, or whether it sprung up spontaneously in course of nature. It is possible in animal physiology that parents afflicted with disease from their very youth may produce isolated examples of offspring perfectly healthy; so it seems possible, and admitted on

all sides, that variegated plants will produce numerous seedlings as healthy and as heavily charged with chlorophyll as their grandfathers and grandmothers and great-grandfathers and great-grandmothers, if ever they had such venerable kinsfolks. But Mr. Darwin says that "analogy is a deceitful guide." Is it not so in this instance? Ask all the best gardeners in the country who do not adhere with staid pertinacity to "set rules"—of course, we may be open to such a charge—and ninety-nine out of every hundred will tell you that the variegated plants committed to their care, and under their most diligent scrutiny are just as healthy and nearly as patient of fatigue as other cognate species with more perfect (?) digestive and respiratory organs. There are as little appearances of premature decay and wearing out amongst them, and their numbers are fast increasing, than among their more gigantic congeners. Do Mr. A. Henry and those who think with him place Golden Chain and Dandy Geraniums on the same footing as Flower of the Day and Countess of Warwick? Surely not. Their malady cannot be of so malignant a nature. We might just as well affirm that Tom Thumb and Frogmore, because they are comparative dwarfs to Glendinning Scarlet and Cerise l'unique, were also in trouble. They are fully charged with chlorophyll to be sure, but they are diminutive; and we are fully of opinion that all variegated plants can be encapsulated for no worse trait of character. Mr. Benton says truly that "the tiny midge is as healthy as the antelope."

It is very generally admitted by all those who have thought over the question that variegation is invariably accompanied with a diminution of growth; but we have yet to see with our eyes, although "we have heard with our ears strange things—things too wonderful to understand," that diminution in stature is accompanied with disease. You may call it retrogressive variation—if you have any sympathy with the leanings of the floral-loving community you will be obliged to call it progressive variation; but you must first tell us the symptoms of the disease, and point out one single anomalous instance of its fatal effects before your theory is satisfactorily established. Disease, as we understand the term, is either curable or incurable. If these plants are the produce of some deficiency in the organs of reproduction and defective in turn, why is their existence indefinitely prolonged? Why is it they do not pine away and die, or else revert to their original prototypes? It is strange their absorbing, digestive, and respiratory organs are in the very best working order. Brilliant Geranium does its duty quite as well in the hands of the cultivator—and what it wants in rampant growth it yields in abundance of bloom—as its elder congener Tom Thumb, from which variety it sprang as a sport or variation; so does the variegated Alysium, and so does the variegated Balu, and many other things which might be mentioned. Such are a few of the examples of the plastic power of Nature which have been produced not by manipulation, probably not by accident, and which might have escaped almost scatheless had the tinge been anything else but variegated. Mr. A. Henry strikes the key-note with undeniable force and accuracy, and shapes his language in a more modified tone thus—"That if it is not disease it is an affection of the plant entailing impaired vigour, and, I hold, diminished growth, whose true cause, whether originating in the seed or occurring in the bunch it is alike desirable to have ascertained; for there is at present a rage for these variegated things, and if the laws which produce or affect them can be clearly shown, then it will be profitable to some and instructive to all to know them."

That is the point I contend for, and so long as morphologically and physiologically speaking, variegated plants enjoy unimpaired health, so long as their organisation is complete, so long as the assimilating process goes on increasing their bulk, I shall always believe, even the most questionable amongst them, to be no less constitutionally and anomalously different from their lustier congeners than the Red Indian from the Esquimaux. Both may not live and thrive under the same treatment, but it is possible to keep them both alive and equally healthy. Doubtless, there are many instances either unobserved or uncared for, where a wonderful "struggle for existence" goes on to the discomfiture and, in time, dissolution of the weaker party. If a row of Limes and variegated Hollies were planted alternately at 6 feet or even 12 feet apart, you would in a very few years see struggle for existence with a vengeance if you allowed the Hollies to remain; but if you transplant them to proper positions in favoured localities and use the pruning-knife with discrimination, you would in course of time have magnificent pyramids amply

repaying any labour you might bestow upon them. If we wish to be successful with anything, we must use the means.

We do not require two distinct freaks of Nature to be designated by synonymous terms. They are evidently distinct in their general appearance, and sufficiently dissimilar in physiological structure so as not to warrant such familiarities with their habits. Every practical gardener can tell that particular kind of discolouring that indicates disease. You will occasionally see the bleached sickly-looking appearance of some individual branches of Camellias in a Camellia-house. Nobody but a tyro would graft any of these branches with the view of sending it out as a variegated plant; for on administering a proper antidote the leaves revert to their original dark green. You will see instances of such like on the Portugal Laurel, which can be quite as easily accounted for and as easily remedied. But you very seldom, if ever, lose a pure variegation. If we want to see disease we do not require to perambulate our stores, our greenhouses, and our parterres, where all are rich in beauty, it may be perfect in health, and increasing in bulk every visit during the growing season. We, on this side the Tweed, only want to take a walk through the great fruit orchards in the vale of Clyde, or in the Carse of Gowrie, to see it in its malignant form. There it may be seen in all its stages of development, indicating debility and death from the scraggy-looking lichen-covered stumps of more than half a century, to the vigorous-looking four-year-old, where canker has only insidiously begun.

I was just wondering in what light the supporters of this hypothetical theory would view the sporting disposition of many varieties of flowers. Do those streaked, blotched, and spotted varieties of the Snapdragon (*Antirrhinum*), which are constantly produced from 1s. packets of seeds in endless diversity of strains, or the "roary" colours of these new fancy Pansies exhibited by Downie, Laird, & Laing, come within the category of disease? Then all these fine Hippeastrums (*Amaryllids*), which I have taken a great interest in for the last half-dozen years, are just so many types of disease. This, of course, will include all the Vittata section, and so many of the Reticulatum and Solandri-form sections as have been induced by manipulation to depart from their normal state. This is not a "cross-breeding" chapter, or else I might dilate on my difficulties and successes in crossing these three distinct types; but I may state that I have seen sufficient to convince me that variegation, which I call simply variation, is not arbitrary in its tendencies to reproduce. There are some species in Nature, however, which say to the manipulator, "Thither shall thou go and no further," as, for example, the mule in animal physiology.

I may tell you in conclusion, that it is only two years ago when I was particularly struck with a few anomalous examples of Camellia blooms. They were the admiration of everybody who saw them, so beautifully were they blotched, and so perfect in form that the lady portion of the visitors especially almost worshipped them. Some supposed that it was a seedling I had been fortunate enough to raise; others whom I considered good judges asked what London nurseryman had supplied it, and what was its name and price. "Surely," say some, as they rubbed the leaves with finger and thumb, "it is not imbricata."

A good judge can pick this variety out among thousands, although not in bloom. It certainly was imbricata, and I have it now in half-dozens completely under my control. I could take either one plant or half-a-dozen plants at one time, and by adopting no very-out-of-the-way method, insure every individual bloom to come blotched. So could I take half-a-dozen at another time and insure nearly every—for it has a tendency to sport with general treatment)—bloom to come self. All the plants are equally healthy, equally vigorous, showing not the slightest emblems of disease, unless it be the variegation in question, which both ladies and gentlemen prize, and which I am anxious to encourage. I do not believe in keeping secrets of this kind, any more than Mr. Beaton and I shall divulge my practice some other day.—JAS. ANDERSON, *Meadow Bank, Uddingstone.*

A FEW NOTES FROM MY MEMORANDUM BOOK ON VARIEGATED GERANIUMS.

THE summer of 1861 is now brought to a close, and even winter is once more upon us. We have again had the opportunity of seeing the various tribes of bedding plants in the parterre clothed in their meridian splendour. We sometimes talk and sometimes read about the triumphs of the nineteenth

century, and triumphs there certainly are; for instance, we saw the great Exhibition of 1851 raised up as if touched by the magic wand, and we have the contemplated Exhibition of 1862 rising up, if possible, with greater rapidity. We have triumphs in steam, and in electricity; we have triumphs by sea, and by land; in fact, there is no branch of industry but what is marked with progress; at the same time the patrons of horticulture have been doing their duty. During the last few years much has been done to improve the various tribes of bedding plants, and I think no class has so much improved as the different sections of bedding Geraniums; it is on these I purpose making a few remarks. The last two or three years we have had some distinct and fine varieties introduced, and I have, this last summer, had the opportunity of seeing some of the newest and best introduced sorts, as well as the choicest older varieties planted out; I have also had the pleasure of seeing the progress they have made, week after week, since they have been planted out, and making a few notes on their merits, as also their shortcomings.

It is not my purpose in these notes to pursue any systematic course, but to jot down the notes as I have taken them at different times.

The class, then, concerning which we shall make a few remarks, is the variegated section, and foremost among these stand the *Cloth of Gold* and *Golden Fleece*; many encomiums have been conferred on these two Geraniums, but not more than they deserve, notwithstanding Mr. Robson's unfavourable remarks about the *Golden Fleece* a few weeks back.

In the spring, when they were planted out, I was rather inclined to think that *Cloth of Gold* would take the lead, and I believe that it is the most suitable for pot culture during the shorter days of winter; but under the influence of summer sunlight, when bedded out in the open ground, *Golden Fleece* certainly proves its rival, not so much in the superiority of its golden foliage, but in its free and vigorous growth, covering the largest space of ground in the shortest time. These two are unequalled for decorative effect, and no gardener, either amateur or professional, should be without them.

Next cometh *Golden Vase*, a striking improvement upon *Golden Chain*. It is of vigorous growth, yet neat and compact, with broad golden margin, finely contrasted with a bright green disk and dark zone, producing an abundance of large trusses of dark shaded cerise blossoms.

Golden Tom Thumb next follows in the train, with fine broad golden margins, increasing in beauty with the growth of the plant, showing a bright green disk, with a dark zone, and a mass of bright scarlet blossoms.

Golden Harkaway is much after the habit of the old *Harkaway*, which Mr. Beaton used to write so much about four or five years ago; it has beautiful golden foliage, and would be useful either for vases, for small beds, or for margins round larger beds.

Yellow Belt, we believe, will prove a gem for the flower garden, but we have not yet seen it sufficiently developed in the open air as to be able to judge of its real value for bedding purposes.

Alma is of dwarf, fine, compact habit, with a broad distinct white margin, producing an abundance of bright scarlet flowers, a decided improvement on *Flower of the Day*, and unparalleled for a front row in ribbon-borders.

Silver Chain is, if possible, superior in some respects to *Alma*, though its blooms are not so bright, nor, I believe, so plentiful, but the foliage is a brighter green, with a purer silvery margin; it is very effective either employed as an edging plant, or used in groups in geometrical patterns.

Bijou is much stronger and more vigorous than the two preceding, although out for several years; it is one of the most useful variegated Geraniums we have, particularly where large masses are required for ribbon lines and large beds, being of free growth it soon fills its allotted space; it produces an abundance of large trusses of bright scarlet flowers, well thrown up above the foliage; it looks well from the time of being planted till deprived of its beauty by frost, and is but little injured either by hot sun or heavy rain.

Beaton's Variegated Nosegay is very free and vigorous growth, distinct in habit, with broad green shaded white margins, moderate trusses of red tinted flowers; a good useful bedding variety.

Calford Beauty is of extraordinary free growth, richly variegated, with broad light sulphur margins, and produces an

abundance of bright dazzling scarlet flowers; one of the most useful of its class.

Maid of Orleans is much more dwarf in habit, very compact in growth, fine rich variegation, large trusses of scarlet flowers; a desirable variety.

Hedersonii is after the style and habit of Flower of the Day, quite as robust in growth, with a purer white margin, free bloomer, large scarlet truss; a charming variety.

Oriana is quite distinct from all other varieties, of medium growth, sulphur margined foliage, bright pink flowers; a desirable variety for small beds, possessing a novel appearance.

Emperor is possessed of a purer white margin than either Alma or Calford Beauty, with a fine green disk, large noble scarlet truss, useful for all decorative purposes; an appropriate name for such a noble variety.

Annie expands her lovely trusses of bright scarlet flowers very freely over her light sulphur margined foliage; extra good.

I cannot speak so favourably about the *Countess of Warwick* as a bedding variety, for, as Mr. Robson has already remarked, its dark red or brown zone gives it a dingy appearance when viewed at a distance, but for pot culture it is very useful; it has bright scarlet flowers.

Mrs. Lennox and *Maid of Orleans*, I think, are about identical with each other, possessing pure silver margins, bright green centre, fine scarlet flowers produced freely, of free and vigorous growth; both extra first-class bedding varieties.

St. Clair is new and novel in colour, dark pink blooms produced freely, fine silver margin; first-rate for bedding purposes.

Shotisham Pet has broad white margins, the young leaves disclosing a red zone, which fades with the development of the leaf; brilliant scarlet, or dark cerise flowers; a cheerful variety.

Perfection, dwarf, spreading habit, with a pure white margin, bright scarlet truss; good either for ribbon lines or groups.

Attraction is a very attractive variety, with white margin, fine red zone or inner belt and green disk; pink truss; excellent either for beds or for conservatory embellishment.

Burning Bush is valuable either for flower garden or for conservatory decoration; its peculiar leaf tint, when grown as a pot plant, gives it a charming effect under glass; its fine scarlet flowers are produced freely, with its white-margined foliage, surrounded with a beautiful red zone, and green centre; extra good.

The *Rainbow* is a very fitting name for such a peculiar variety, with its various rings or markings of red, white, and green; it has deeper scarlet flowers than Burning Bush, and is a useful bedding variety.

Fountainbleau is a rich, fine, dwarf variety for small beds or margins, with bright pink flowers, inner red or pink zone, clear white margin; a very desirable variety either for bedding or pot culture.

Of *Mrs. Pollock* I cannot speak in too eulogistic terms; it is one of the finest variegated Geraniums that has ever been sent out; is entirely new in its rich combination of bright green, red, crimson, and golden yellow foliage; and is the finest variegated Geranium we ever saw for conservatory decoration, and thrives equally well in the open air, and develops its rich combination of colours to greater perfection; in addition to its exquisite foliage, it produces fine trusses of bright scarlet flowers.

While I have been penning the above, I have been thinking of a new variegated plant for edging, and one that I do not remember having seen mentioned in these pages, it is the variegated Ivy; it might be used as a permanent edging plant, and when the half-hardy bedding plants were removed in the autumn, their place might be filled up with dwarf coniferous plants, or any other dwarf evergreens, and the variegated Ivy, as an edging, would produce a charming effect. I think that Mr. Beaton ought to take the subject in hand, and if the merits of the variegated Ivy are but duly appreciated, it will, I have no doubt, occupy a very important position in the parterre.—R.

GAZANIA SPLENDENS AS A BEDDER.

AFTER all the laudatory notices of this flower it will never be a general bedding favourite—at least, so I conclude, judging from the numerous disparaging remarks I have heard made during the past season. Mr. Beaton's hygrometric belt was only an offspring of his very vivid imagination. I tried the slashing of the jackets of many blooms, and achieved nothing but a lot of dis-spotted

sprawling, cavalier-like flowers; more ugly than the shut-up form, if anything can be more ugly.

I have been intensely disgusted with *Gazania* this season. I edged three vases with it, and they were all very well in the early part of the day; but when visitors began to arrive in the afternoon, and cool of the evening, then *Gazania* was not to be looked at, except in its porcupine state—looking like multiplied starfishes, in that contracted state which a dose of strychnine is said to put its victims in. Now, I can conceive *Gazania* being quite at home amongst Ferns on roeteries in that cool moist shade that this tribe chiefly like; or, as a bedder round fountains, or as a decorative plant in wilderness embellishment, or in gardens on still cold soil, or it would serve that gardener's turn well who wanted a great display in September; for, its appearance during the last September melted me into such a charitable mood that I was near altering my previous judgment. Now the frost is gone *Gazania* is black.

The enclosed leaf is from a *Camellia Juliette*, bought at the sale of a gentleman's stock near Nottingham. On the sale day a strong biting north-easter was blowing (April), and the *Camellias* had only just made their new wood; they were put out on the lawn for the convenience of arranging in lots. I noticed this peculiar indentation on the new leaves, and the yearly growth during three successive years is always the same. What is it? Does this account for its backwardness in growth and blooming? It is the latest we have.—N. H. P.

[We think Mr. Beaton put *Gazania splendens* in its proper place when he said it was the best bedding plant of that colour for fashionable private gardens, when the company "go round" in the forenoon; and about one of the worst for public gardens, because the public go round in the afternoon when all *Gazania* flowers, and many others, are closed. *Camellias* with serrated leaves like the one you sent are plentiful. Indentations on such leaves are no mark for identification.]

AUTUMN-FLOWERING CINERARIAS.

ALL who have a large space of glass to decorate with flowers, know well what a hard matter it is to find plants to do so in the autumn. Having felt this want myself, I looked at all plants that had the appearance of affording me a resource, from which I might be able to fill up this gloomy gap. I did not look in vain, as the details of growing the *Cineraria* for that purpose, here given, will show.

I do not assume that this plan of growing them is new, but I have never seen it practised by any other gardener, so that a few hints on the subject may not be uninteresting to some of your readers.

I sow seeds in March—the middle of the month is best—in a seed-pan, placing it in a gentle hotbed, with the usual care required for all small seeds. The seedlings will by the end of April be large enough to place in small pots. This done, place them for a few days longer in this mild heat, and then remove to the best of all places for growing the *Cineraria* in pots—namely, the cold frame. Here they are to remain till all danger of frost is past. Then prepare a piece of ground, the size of which must be determined by the number of plants you intend to grow, by giving a covering of 6 inches of good mellow loam—rotten manure and leaf mould on a north border—and this well forked in will not fail to produce fine plants.

The ground ready, the first week in June is early enough to turn the plants out of their pots into the border. Eighteen inches apart are not too far to allow the free use of the hoe, and for copious waterings, which they must receive in dry weather.

Some precaution will be necessary, on their first turning out, to prevent the attacks of vermin, &c.; but with the above previous preparation, little will be required to be done to them till the middle of September, at which time, if they have progressed satisfactorily, they will exhibit unmistakable signs of flowering;—not mere resemblances of flower-stems, and flimsy side shoots, but fine stout robust plants, which if carefully taken up and potted, will produce flowers equally good, but larger and more numerous, than those produced from pot culture.

Little remains for me to add, but that they must return them again to their old favourite quarters, and from there to the greenhouse, conservatory, or sitting-room, and if the heat of these places can range from 45° to 50°, a fine display of bloom can be obtained through the dullest months of winter.—J. C. C., Wakehurst Place.

THE IN-DOOR PLANT CASE.—No. 4.

(Continued from page 166.)

AMONGST those persons who are fond of plants, and who delight in the beautiful shapes, and in the sweet scent of flowers, how very commonly we hear the remark, that they cannot possibly have flowers in their rooms, because they are so busy, or so much away from home, that it is really hopeless to look for success in growing them. Some die for want of water, and others because they have been soaked too much; some are scorched up by the dry, hot air; and others, again, require more heat than they can receive in sitting-rooms. A Fern shade is generally the last thing tried, and even first-rate gardeners find that this needs some attention to keep the fronds in freshness.

Yet, it is hard to be quite deprived of flowers. There is something pleasant even in the thought of having them growing round us.

I should like, then, to describe a very easy plan, one that ought not to come to any damage in the owner's absence from kindly meant, but mistaken over-care, and one that is capable of affording very great delight in return for only some rare half-hours' tendance. I have had myself a Fern-case with a few little flowers also, the inside of which was certainly never touched more than once a week.

My plan used to be to water the Ferns a little, and to moisten the sand fairly in the box, then to place the upper glass so as to allow a little air to enter, and thus even when heat was given I have left my plants untouched for a fortnight, or even for a still longer time, while the rarest thing has been to open it within the week. My own great delight is in a case of Ferns and blue Lobelias, small red Geraniums, Anemones, little Blue Bells or Snowdrops, and the white waxen Cyclamens with their deep rose-purple blotch. Flowers such as these grow so very charmingly, and look so at-home with Ferns, and though I know a great deal is said of the current of air required by all Cape Heaths, I have certainly known some brought just in blossom, which have continued opening out their lovely spikes of flowers, and have looked most thriving for a very long time indeed. They cannot, however, bear a moist air at all; they lasted so well, only when vapour was scarcely present, and where, though the Ferns that filled the case were standing in moist sand, not very greatly watered, the Heath itself was sunk in a double pot. Where a pot is thus protected from a current of dry air, the roots are large enough not to dry up suddenly. The double pot is, therefore, in this case needed for protection from over-moistness. Pots (small 60's) containing two red Van Thols, a tumbler full of Snowdrops or of Scillas dropped in here and there, a little blue Lobelia, or, as I said, an Erica, are amply sufficient for lighting up the case, and when these flowers are used, the usual treatment of the Ferns may in every respect be continued without the slightest reference to these things while in blossom.

I am at present so occupied with experiments that I can hardly keep one case for mere ornament; my principal case containing Dracenas and Begonias, Ferns and Camellias, in a most promiscuous array. The Camellias, however, open out most charmingly above the Ferns at one end, while Begonias, Dracenas, Gesneras, and Lycopodium thrive delightfully at the other. I mention this because Camellias, and Ferns, and Begonias are not more alike than Ferns and Heaths, and yet both are thriving. At the warmer end of the case the stove Ferns do best. Pteris tricolor is a little gem in front; P. argyrea waves its beautiful striped fronds high over head; and Adiantum formosum, my favourite Fern of all, Adiantum cuneatum, and A. setulosum, are rising from a thick green carpet of most thriving moss. Selaginella Lobbi grows up tall and stemmy, and then droops down a Fern branch, whose crumpled edges catch the light, like

dew drops. Some Davallias are beautiful at the other end, and several Chinese Primroses continue in splendid blossom. This case, therefore, I cannot call a fernery.

The main difficulty in keeping Ferns in winter arises; (as I have been told by first-rate Fern growers, as well as having observed it in my own plants repeatedly) from the difficulty of "ousting" the moist, damp, clinging, unhealthy vapour which stands stagnant about their stems, bathing the leaves in a most unwholesome bath.

Many Ferns, of course, do not require heat, and thus, of course, no heat is provided for them. They do require moist air, and that they have abundantly; but then arrives one of those damp, dark spells of gloomy, foggy weather; warmth is not wanted actually, but a change of air is necessary; moisture is still required, but that which has been loading all the air so long is a simple poison.

To open the cases to the air of rooms which in such weather we naturally heat and dry, is a certain evil; to leave things as they are, results in decay and blackness.

It is here, then, that the heating apparatus, even for a Fern-case, seems to me so necessary. The constant upward tendency of the freshly-warmed air drives out of course, or circulates all the vapour clinging to the leaves, which is in its turn rapidly dried, or, at any rate, changed and purified. The heat need not be maintained if the Ferns are so hardy that it is not required; but I confess I have seen but few which do not thrive the better for a little warmth.

My acquaintance with Ferns is, however, limited. I have a few great favourites, and to them at present my collection has been confined. I may as well mention, also, that my Fern-growing began in a most unorthodox manner; merely a few pots put in amongst other plants, and my knowledge of their culture is utterly and entirely picked up and purchased by experience.

For potting Ferns I find nothing at all comparable to charcoal drainage over a single potsherd or zinc cap, then a handful of cocoa-nut fibre, and then a soil made of two parts of cocoa-nut dust to one of sand, charcoal, and peat soil, or failing that leaf mould. I have, however, often bought soil at nurseries, and, perhaps, the leaf-mould from thence is really mixed-up soil.

The cocoa-nut refuse can be obtained at Kennard's, Swan's Place, Old Kent Road, at 6s. a hundred-weight. It is exceedingly light, so a small quantity would go an immense way in potting.

I proceed now to name the Ferns and Fern-allies which I have found to be sufficient for a four-foot case. All those marked 1, should be at the warmer end, but a layer of damp sand must protect the pots from resting immediately on the hot-water tank; 2, will indicate the more hardy kinds.

- | | |
|----------------------------|------------------------------|
| 1. Adiantum cuneatum, sus- | 1. Selaginella Lobbi. |
| pended or in pot. | |
| 1. A. formosum. | 1. Davallia canariensis. |
| 1. A. setulosum. | 2. Lastrea filix-nas. |
| 1. Pteris tricolor. | 2. Adiantum capillus-Veneris |
| 1. P. argyrea. | (Maiden-hair). |
| 1. Davallia dissecta. | 2. Pteris serrulata. |
| 1. D. bullata. | 2. P. geraniifolia. |
| 1. Lycopodium cæsia. | 2. P. hastata. |

For both ends the Lycopodium denticulatum makes the best of carpets, if kept well watered, and forced to lie on the surface. If it sweeps down the side of its own pot it rapidly decays in the dark and damp.

The Ferns I have mentioned are enough for a charming group. There should, however, be one added for the centre, if a Heath is not placed there, which must be chosen specially for its waving Palm-like shape.

For flowers to keep up as an under-growth, I have already mentioned blue Lobelias, Scillas, Snowdrops, and red Van Thol Tulips with the lovely little Persian Cyclamen as amongst the most charming for the cooler end. At the other end I fancy nothing would be more

suitable than the little plant suggested last week by one whose suggestions would carry with them weight. I allude to the *Stenogaster concinnum*, for which plant-see possessors should be on the look out.

There are also several low-growing or trailing plants with bright-coloured blossoms, either of blue or white, which would enjoy the warmth, and look most charmingly peeping amidst the Ferns.

It will be understood in this instance that I have taken for granted that the case is heated; not, perhaps, to a great degree, but at least made warm enough to cause the stove Ferns to thrive.

If hardy or greenhouse Ferns should be used exclusively, with Snowdrops and Scillas for their bright specks of colour, the warmth is of course unnecessary, except in the days when the damp, stagnant atmosphere must at least be banished.

The list I have given is a very small one, just things that I know well, for a single group, for my knowledge of Ferns is so little extended, that it is very likely many charming sorts are still quite untried by me in these cases; if so, however, I may hope in future to be able to add many other lists, as each sort is proved as to its peculiar growth.—E. A. M.

WINDOW PLANTS.

I LIVE in a row of houses facing about south-east, and am anxious to have flowers in my window. The ordinary plan is to benefit passers-by, but I want it for my own pleasure. Could any correspondent kindly suggest some structure to be placed outside, which would not be a dis-sight: so that by opening the lower part of the window it would give one the benefit of the plants, and at the same time avoid the dust, &c., of the room? It must, of course, fit close so as to exclude draught.—X. T.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE November Meeting of the Entomological Society was held on the 4th ult. The President, J. W. Douglas, Esq., being in the chair.

Mr. Kirby exhibited a large box of Butterflies and Moths from North America. And Mr. Samuel Stevens a fine collection of insects of various orders, sent from Japan by Mr. Fortnum, including many species of great rarity, including the singular Damoister Elaptoidea (one of the Carabidee Beetles), two new species of the genus *Papilio* (one of them allied to *P. Paris*, from China).

Mr. Adam White exhibited some interesting insects of various orders, collected by Mr. Rayner, surgeon of H. M. ship *Herald*, during its voyage to the South Sea Islands: likewise a fine, new, and undescribed species of Bombyx, brought from India by General Sir J. B. Hearsey, for which he proposed the specific name of *Hearsyia*.

Mr. Beading exhibited fine examples of *Leuconia putrescens* and other Lepidoptera, from Torquay and other parts of the south of Devonshire.

Mr. Knaggs exhibited the cocoon, or moveable case of a very singular shape, formed by the caterpillar of a species of *Psychre*, from Australia. And Mr. Miller exhibited some living caterpillars of a species of *Incurvaria* (a genus of minute Moths), found feeding on fallen leaves.

Mr. Desvignes communicated descriptions of two new species of Ichneumonidae, belonging to the genus *Ephialtes*.

Mr. MacLachlan read a paper on the British species of Phryganide contained in the genus *Stenophylax* of Kelenati.

Mr. Adam White made some observations on the injury, amounting to several thousand pounds per annum, caused to *Ginger* brought to this country from the East Indies, by a small Beetle belonging to the family *Plinidae*, the *Lasiolema testaceum* of Stephens; and to *Macaroni*, by *Sitophilus Oryze* (a small Weevil allied to the *Calandragonaria*).

Mr. Tegetmeier called attention to a statement respecting the development of a green bee, lately published by Professor Leitch, who asserts that the production of the perfect queen is due, not as has been supposed, to the larva being fed on a peculiar food, but to increased temperature, and that the isolated position

of the royal cell enables the worker bees to cluster around it, and by their rapid and increased respiration to produce the degree of heat necessary. Mr. Tegetmeier stated that his own observations tended fully to support this theory.

Mr. Waterhouse read the description of two curious *Careu-lionidae*, from Van Diemen's Land and Adelaide, on which the claw-joints of the tarsi are wanting.

Mr. Janson read some observations on two species of British *Staphylinidae*—*Homsloia subterranea* and *Haploglossa pulla*.

The Secretary announced that a new Part of the Society's "Transactions" was ready for delivery to the Members.

WORK FOR THE WEEK.

KITCHEN GARDEN.

IF frost should set in every advantage must be taken of it, to wheel manures and composts on the various quarters requiring it, and if it cannot be trenched in at once let it be laid in heaps at convenient distances, and covered with soil. Ridged ground may also be occasionally forked over and knocked about to expose fresh surfaces to the action of the atmosphere. The occupation of the ground by crops suitable as food for a variety of insects, in the course of a series of years, brings a vast amount of such depredators into a garden. The invention of methods for their destruction often taxes the ingenuity of a gardener to a considerable extent. The analogy existing between insect and vegetable life restricts the choice of means, for that substance which may be provided for the destruction of the insect may injuriously affect the health of the vegetable. Hence the necessity of caution in the use of materials. There is, however, one substance not open to any objection, which may now be used with advantage: in land from whence the crop has been removed—viz., lime. Ground cropped the preceding season with Carrots, Parsnips, or Potatoes, and found (as is frequently the case at this time) infested with insects, should have a good dressing of lime dug in. *Beans*, where they have been planted in rows and have made their appearance above ground, draw the earth in ridges on each side of them, so as to afford some little protection from cold cutting winds. Peas in rows should be similarly treated. *Carri-flowers*, watch narrowly for slugs amongst the young plants, and keep them free from dead leaves. If any are planted in pots for the purpose of protecting them during severe weather, they must be carefully attended to with water, or in the spring it will be found that the time and trouble given to them had been uselessly expended. *Lettuce*, the young plants in frames to bare all the air that can be given them in mild weather. Keep them and also those on the borders free from dead leaves and litter of all sorts that is likely to harbour slugs. *Rhubarb*, take up and pot old roots for forcing if required, or they may be laid in a Mushroom or any other house where heat is applied, and slightly covered with soil. Surface-stirring amongst young growing crops should now be as diligently followed up as in the summer when vegetation is more rapid. Indeed, there is no season, if the weather is favourable, when those operations should be neglected; frequent pulverisation of the soil acts as a great check to the penetration of frost in winter, and to the evaporation of moisture in summer.

FLOWER GARDEN.

Except alterations are on hand, there will be but little requiring attention here at present beyond the cleaning up of leaves, and putting the borders, &c., into order. Sweep and roll the walks frequently so as to keep them clean and smooth. Turf will also require rolling frequently to keep it smooth. Collect as many leaves together as possible, they are valuable for mixing with fresh manures for fermenting purposes, as they not only correct its rank and violent fermentation, but preserve it at a more steady and uniform heat for a greater length of time, or when allowed to decompose in a heap for mixing with the soil in the flower-beds and borders.

FRUIT GARDEN.

Proceed with the planting of fruit trees in open weather, and if the soil is old let each tree have a good portion of fresh soil, maiden loam, if possible, about its roots. The pruning and nailing of all sorts of fruit trees, except Peaches, Nectarines, and Apricots, to be regularly prosecuted. By performing whatever can be done now, a greater margin will be left for the more busy operations of spring.

STOVE.

I have little to add to former directions except that it will be

well to reduce the temperature 2° or 3° night and day. Keep all plants that are making growth at the warmest, and all such as are well ripened off at the coolest and driest end of the house.

GREENHOUSE AND CONSERVATORY.

A little fire heat will be necessary here during cold, damp weather, to allow the admission of fresh air to carry off superfluous moisture without lowering the temperature too much, to be applied during the day, and all watering to be done in the morning, that the atmosphere may get moderately dry before night, as a damp, stagnant atmosphere is especially injurious to flowers—such as the early Camellias, whose blooms soon become spotted and decay when the air is damp. Pelargoniums to have their shoots thinned and neatly tied out to stakes. Keep them thin to produce stocky plants, and fumigate or apply Gishurst to the first appearance of green fly. See that the young stock of *Holiotropes*, *Cyclamens*, Chinese Primroses, *Ageratum*, Scarlet Geraniums, and other plants, grown especially for winter decoration, have nice, light situations, and regular attention, as regards watering. As many plants suffer from drip at this season, a careful look out should be kept, and either the cause remedied or the plants removed.

FORCING-PIT.

The following things may be introduced to heat if not already done. *Rhododendrons*, *Azaleas*, *Kalmias*, and *Persian Lilies*, Sweet Briars, Moss and other *Fosces*, *Daphnes*, *Aene Boleyn Pinks*, Dutch bulbs, &c., if they had received the necessary treatment through the summer.

PITS AND FRAMES.

If former directions have been carried out, the plants in these structures will present a dwarf and robust appearance, thus being well fitted to bear privation of light for some time, if severe weather should ensue. Damp has accumulated very much of late, owing to the heavy rains with which we have been visited. This may be removed by giving air at noon on sunny days, but where the pits are heated with fires a dry atmosphere may be obtained by putting on slight fires, at the same time allowing a free circulation of air amongst the plants. This will also remove all damp from the inside of the frames and put them in proper order, so as to be ready when severe frosts set in.

W. KEANE.

DOINGS OF THE LAST WEEK.

The doings of the week are pretty well a counterpart of those of the last. Protecting Cauliflowers and Lettices from frost, giving plenty of air when fine. Pruning and nailing fruit trees out of doors. Tying Peach trees in house in wet days. Pruning and clearing second vineyard, and filling the floor with old Geraniums, and the shelves with young Scarletias taken up from a bed out of doors, where they had been rooted with glass over them, so that they might be safer in the house, and save us the trouble of covering them. They were inserted in the bed in the autumn to save time, and also because at that time pots and boxes were scarce. Took much of the leaves off the Figs, find that the Figs now sent to table come out again unclean, a sure sign they are not worth eating. Will remove all bigger than a pea or small bean, and let them rest until early in spring, keeping the plants just as dry as the plants will not suffer from drought. Wheeled manure in frosty mornings, and took every favourable opportunity to get the pleasure ground cleared up for the winter, the ground being damp enough for digging.—R. F.

TO CORRESPONDENTS.

* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

VALLA TA PURPUREA CULTURE (A New Subscriber).—The treatment of *Vallota purpurea* is the same as the treatment of *Agapanthus umbellatus* in every respect; and the treatment of bulbs is very nearly the same, save as the treatment of a pot *Toum Thomb* Geranium in your round, out that *Toum* would stand more heat with less burn than the *Vallota*. As for the size of pot, small bulbs of *Vallota* require little pots, as No. 60's; half-grown bulbs to be in 48's; and full-grown ones to be in No. 52-pots. *Vallota* never comes in very thickly in summer; and young plants will grow and increase in size in one-half the time if they were planted out in warm borders when the bedding-out is finished at the end of May, and to be taken up with the bedding-plants in October. That is the sure way to get bounding bulbs of *Vallota*, and of *Sp. bellina* or *Amaryllis formosissima*, in the shortest time from the smallest fry of offset bulbs. The *Vallota* blooms from June to October—that is, some of the bulbs will flower in June, some in July, and some in August and September.

COAL ASHES FOR PROTECTION (Idem).—They are famous protection to bulbs against frost; but *Kanunculus*, *Tulips*, and *Crocuses* do not require such protection at all in any part of the three kingdoms, and they do much better without.

WATERING CAMELLIAS (Idem).—Camellias that are full of blossom buds and have healthy roots require as much water as a *Oleander* would need in May and June and liquid manure is not cool for any one plant under the sun in our climate between the autumnal and spring gales or the equinoxes. The buds of your Camellias last year fell off from one of two causes—very bad roots, or a very poor supply of water which was too rich.

SENDING CACTI (A Amateur).—We heard no more of that seedling from *Cacti* or *Epiphyllum truncatum*. All that breed flower in the winter and are dry stove plants. The greenhouse *Cactuses*—or tall *Cacti*, as they schedule them for competition—flower late in the spring. No notice of treatment that we know of will cause either of them to fall off from the end of February to a few weeks later or earlier than their usual time.

CAMELLIA IN A DWELLING-HOUSE (R. H. Glossop).—You will see an answer to another correspondent, which will instruct you what to do. Keep it as cool as you can without being frosted, and the leaves frequently sponged with tepid water. For ten penny postage stamps you could have from our office "A Manual for Gardeners for the Many," which will tell you how to manage throughout the year.

WORK ON PLANT PROPAGATION (A Amateur).—Our "Garden Manual" gives directions for the propagation of all garden plants. So do the "Cottage Gardener's Dictionary." Either can be had free by post from our office. The Manual for twenty penny postage stamps, and the Dictionary for sixpence each.

NEW GRAPES (Thomas Higgins).—We cannot say where you can get plants of the Grapes you refer to. We would advise you, as a rule, always to consult those nurserymen who advertise fruit trees in our columns. They have all respectable establishments, and if one or other of them cannot supply you, they will either obtain the trees for you or tell you where you can get them. Do not buy from Doyne or Doyne & Baylis's. Berries can be had from any of those parties. They are now pretty generally grown in nurseries.

FIFTH TREES (J. Z. Chelsea).—We would recommend you to have *Pears* instead of *Cherries*, and these should be—*Marie Louise*, *Wint' Nedis*, *Joséphine de Malines*, *Knight's Monarch*, and *Berrié de Rance*. The two *Plums* should be *Green Gage* and *God's Golden*.

GERANIUM EMERGING (J. P. Liverpool).—We studiously refrain from recommending any place as desirable to cultivate to. So much depends upon circumstances of which we have no information. Mr. Appleton's time since pointed out Canada as most desirable for a practical gardener.

GISHURST COMPOUND—GREENHOUSE CLIMBERS (J. E.).—If the Gishurst will not stop it will do no harm by falling on the surface of the pots. The *Cobaea scaberrima* would not suit you if not too strong, and it is rather herbaceous. The *Cissus antarctica* would do better—a close evergreen and little liable to insects. We have seen the *Cobaea* fine in such a position.

VERBENAS DAMPING IN A PIT (J. Jones).—You have allowed the *Verbenas* to get too damp in the frames, and we think they have a little both of mildew and thrips on them. The thrips will soon find their way from them to the plants. Take two ounces of flowers of sulphur, work it up into a paste, add pour on that a quart of boiling water, stir and let it settle, and when cool pour off the clear yellowish water, boil two ounces of tobacco in half a gallon of water, strain, and when cool add the sulphur water and mix the two together in a basin, and put in the plants through the plants in the pot to prevent the soil coming out, turn the pot top-sy down, and draw the heads of the *Verbenas* several times through the liquid, and then set them in a shady place for a day; then lay them on their broadsides, and syringe the heads well with water at intervals without wetting the soil. When dry take off a little from the soil, and replenish with fresh silver sand, fresh soil and charcoal dust, and keep them airy afterwards. Thrips should be looked after when making cuttings.

STRAWBERRY-BED (Strawberry).—If you have no other Strawberries than those in pots you may turn out those among plants in the garden. But if you have plants already we certainly should take the best crop from them, and then they will give us more a crop in 1863, which turned out after being in the house, as they will do when turned out now.

SLOWLY-BURNING FUEL—LARGE-LEAVED OAKS (A R.).—You may do much with wetting the ashes, and covering up nicely, and regulating the damper; but you cannot have all advantages in any human contrivance. To secure what you want may be a large expense, and you may not have a good rest at back or sides here the beds do not go, and thus go to more expense for bricks to save a little trouble in the no ring. The Oaks for your purpose would perhaps be *Quercus obtusifolia*, *rubra*, *nigra*, *tinetoria*, *agilicosa*, *aculeata*, *curtis fulva*, *incana*, *curtis Lucombeana*, *rubra salicifolia*. *Agilicosa* is hardy.

OLD VINE-BORDER (A Young Gardener).—Your plan is a very good one. We suppose the spider was too small to be spread and not done enough. The making of the border above the ground level was a good one, and the less you sink below the better you will find it. You may do all you propose and sink about less—18 inches of such soil would even do. Use plenty of the old mortar, and in such soil but little of leaf-mould or peat. It is easy to enrich from the surface. There will be more said on borders in a week or two.

SPAN-ROOFED CONSERVATORY (P. Lope).—We do not think that there is anything the matter with the house. There can be none too much glass if, as we presume, the back upright is wall. Have you enough of air at the top? 40° is long enough long continued to have plants to bloom in winter; 45° at night is better. The Fuchsias blooming depend a good deal on the ripening of the wood and shoots. We think in such a house they could scarcely fail. The Pimeles, Azaleas, &c., depend on being well sunned and aired to set the buds. We wish we could say more to suit you. Do you give air freely in front in summer especially, and now in nice weather?

CONVERTING PART OF A GREENHOUSE TO A STOVE (J. Whitehead).—You might have a sliding iron across the fire at the division, and run the fire bricks across the house in the ten-foot division, so as to heat that independently of the greenhouse. When both places needed heating the slide would regulate the amount of heat to each. This would be the simplest mode. The next would be to have a small boiler over the furnace with two pipes leading to a small wood tank and another to a boiler, and from the boiler tanks lately, and made of making, &c., that it would not be worth while repeating them. Without the tank you might make the flue double in the hot-house part, having it in the middle as well as at the end.

PRUNING VERONICAS (L. K.).—If the Veronicas are the shrubby New Zealand kinds, they should be pruned back after flowering as close as Pelargoniums, unless you are aiming at large bushes of them; then the main canes should be no more than one-half of the strongest and next strongest shoots cut off, and all the very small ones got rid of altogether, by cutting them close to the main leaders. But recollect this difference in the pruning for two objects. There are many "small yellow Cytisus" some of which are hardly in England, and some are not so. Not knowing either your kind, or where you write from, we cannot say: if your kind of Cytisus is ardy or not. The same observation applies to the Veronicas, they are hardy in some places and not hardy in other places. Your place we do not know, and, therefore, we cannot answer the question.

NAMES OF FERTI (Type) No. 1, Golden Noble; 2, Golden Reineette; 3, Roxton Nonpareil; 4, Scarlet Nonpareil. (P. E.)—1, Bourke Pippin; 2, Glen Moree; 3, Winter Nix; 4, Elston Pippin; 5, Coedle Pippin; 6, Dumelow's Seedling; 7, Winter Collin; 8, Monstrous Seedling. (S. Jolton)—A, Conseiller de la Cour; B, Fasse Gildor; C, Duchess of Devonshire. (Ludlow)—You have had a large quantity of Holland and the small russet, city one is Sun Young, a delicious dessert Apple when kept till spring. (E. F. Lombard, Dublin)—You Pear is Beurré Diel.

NAMES OF PLANTS (J. E.)—It is not *Osmunda regalis*, but it is *Osmunda sensilis*, which has distinct fertile fronds. (*Mary Anne*)—You are *Anacallis arifolia*. (*H. H. Myer*)—Both 1 and 2 are forms of *Lactuca filix-mas*, and both belong to the var. *pubescens*, though differing so much in colour and habit. There is a great variety in forms of the same species and the same variety within certain limits. Your plants, no doubt, came from distinct wild habitats, and hence the variation between them. 2, *Lactuca dilatata*; 4, *Polystichum angulare*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE BIRMINGHAM POULTRY SHOW.

EVERYTHING is comparative. We can compare ourselves with the Times. It is not far from Fleet Street to Priory House Square. The man meeting three ribs of beef and potatoes on their way from the baker's (who has not wished when meeting such on their way from church Sunday morning, to help him or herself to one of the smoking, glistening vegetables?) said it was just what he had had for dinner barring the beef. Men have written beautiful and touching things about their return to home and country. Eloquent things have been said about the emotion experienced by old men when they have revisited their colleges for the first time since they left them in youth. Their university lives arise before them, and involuntarily they reckon the years that have passed since they were there, and it may be they ask themselves whether the grey heads, perhaps the bald ones, the eyes that refuse their office without assistance, and the frame that asks for a little more covering every winter, can belong to that bold, bright young fellow, whose portrait still hangs up in the room which "erst he did inhabit." Successful institutions are like the national debt. The men who help to build, who foster and encourage, pass away with their generation, but the institutions remain and flourish. Shakspeare calls two universities twin sisters. We hope the national debt will never have a family.

Our present comparison is, that our feelings are something akin to these when we approach Bingley Hall. The first crowing of the cocks that salutes our ears carries us back thirteen years, and recollection not only causes surprise at that which has been accomplished, but it raises our admiration at the perseverance and constant wisdom that have dictated all the resolves of the Council that directs this large undertaking. A poultry and cattle show in the ordinary acceptation of the words does not fill a very large space in men's minds. At Birmingham it comes somewhere about, rather before Christmas, and is associated with goose clubs, displays of fruit in grocers' windows, fat meat, and bougins of holly and mistletoe. Hotels are too full; thirty thousand of extra people through the streets, and it is the busy week of the year with shopkeepers. No one would deny that these things are the result of the Show, but too many are careless

about the funds that support it, and do not trouble themselves to think how it is carried on. Prizes amounting to more than 1000; a Show that involves the absolute necessity of a *body of police*; a heavy policy of assurance; a supply of food that reminds any one of the provision made by a city in expectation of a siege; a numerous staff of volunteers to direct, and paid men to carry out an amount of actual labour no one would believe unless they saw it, or participated in it; a heavy responsibility, both mental and pecuniary; all these things form the Birmingham Show, and involve the necessity of constant care, foresight, and supervision. The correspondence and the accounts are voluminous, and the Show of 1861 is hardly closed before the Council meets to consider that of 1862.

If there was ever a time when this great Meeting assumed more than usual importance, it may safely be said it is the present. There is more thought of poultry now than there ever was in the memory of man, and it is assuming the proportion of a food question. The exhibitions that have sprung from that which held its first meeting in Birmingham fourteen years ago, have done for poultry that which the agricultural meetings did for cattle. They point out the breeds that suit certain climates and soils, and, quite as important, they prove which make the best and speediest return in the way of food for that which they consume. If we were to view the question in a less serious light, we would say the originators of, and those who carry on this monster meeting, cater for the pleasure of many of our best and highest in rank and worth. They have provided a healthy recreation, and a competition which has no bitterness. The single-minded men who founded this Show may find their reward in the perusal of the lists of exhibitors and subscribers, and the unrivalled attendance of the week, especially the private view on Monday.

Seeing the poultry is not judged till Saturday, and that this must be in the printer's hands early on Monday, we are compelled to confine ourselves to these general remarks. We must defer our review of the classes till next week, when we hope to give the detail of increasing success, and to record that the exertions of our good friends who devote so much of their time, means, and talents to this useful work, are appreciated by those for whom they labour, and supported accordingly.

The following is the list of awards of the Judges:—

DORKINGS (Silver Grey)—First, Mrs. F. Blair. Second, Mr. Arnold. Third, Mr. Drewry. Fourth, Lady S. Des Vaux. *Chickens*—First and Third, Mr. G. G. C. Street. Hon. Capt. Hays. Fourth, Mr. F. Blair.

DORKING (Coloured except Silver Grey)—First, Mr. A. Potts. Second, Capt. Hornby. Third, Mr. C. H. Wakefield. *Chickens*—First and Cap. Capt. Hornby. Second, C. H. Wakefield. Third and Fourth, Hon. W. H. Lyne.

DORKING HENS (any variety)—First, Lady L. Tlynne. Second, Capt. Hornby. *Pullets*—First, Capt. Hornby. Second, Mrs. Blair.

DORKING (White)—First, Mrs. Henry Fookes. Second, Mrs. M. A. Beadmore. *Chickens*—First, Capt. H. Townsend. Second, Mrs. M. A. Beadmore.

SPANISH—First, Mr. John Martin. Second and Third, Mr. R. Teebay. Fourth, Rev. C. Lowndes. *Chickens*—First, Mr. S. H. Hyde. Second, Mr. J. R. Robbath. Third, Mr. Henry Lane. Fourth, Mrs. R. Teebay. *Hens*—First, Mr. J. K. Fowler. Second, Mr. Geo. G. Rice. *Pullets*—First, Mr. J. R. Robbath. Second, Mr. J. K. Fowler.

COCHIN-CHINA (Cinnamon and Buff)—First and Cup, Mr. Henry Tomlinson. Second, Mr. Thomas Stretch. Third, Mrs. Henry Fookes. *Chickens*—First and Cup, Mr. Henry Tomlinson. Second, Mr. Thomas Stretch. Third, Mr. J. W. Kellaway. *Hens*—First, Mr. Charles Felton. Second, Mr. Thomas Stretch. *Pullets*—First, Samuel Statham. Esq. Second, Miss V. Musgrave.

COCHIN-CHINA (Brown and Partridge-feathered)—First, Second, and Third, Mr. Cartwright. *Chickens*—First, Mr. E. Judman. Second, Mr. P. Street. Third, Mr. C. Felton. *Hens*—First, Mr. Cartwright. Second, Mr. T. Stretch. *Pullets*—First, Mr. T. Stretch. Second, Mr. Cartwright.

COCHIN-CHINA (White)—First and Second, Mr. R. Chase. *Chickens*—First and Second, Mr. R. Chase. **FRIGATA POLARA FOWLS**—First and Second, Mr. R. Teebay. Third, Mr. E. H. Cragge. *Chickens*—First, Mr. R. Teebay. Second, Lady Louisa Thynne.

MALAY—First and Second, Mr. Charles Balmace. *Chickens*—First and Second, Mr. N. Evans. Jun.

HARDING (Golden-pencilled)—First, Mr. E. A. Wilkinson. Second, Mr. James Mann. Third, Mr. John Lowe. *Chickens*—First, Mr. E. A. Wilkinson. Second, W. R. Clayton. Esq. Third, Mr. James Mann.

HARDING (Silver-pencilled)—First, Mr. D. Harding. Second, Mr. W. H. Kerr. Third, Master T. B. Keeble. *Chickens*—First, Mr. John Martin. Second, Mr. Jas. Mann. Third, Mr. D. Harding. *Hens*—First, Mr. W. H. Kerr. Second, Mr. Jas. Mann. *Pullets*—First, Mr. Jas. Mann. Second, Mr. Fred. Webster.

HARDING (Golden-spangled)—First, Mr. N. Maylow. Second, Mr. W. R. Lane. Third, Mr. W. B. H. Potts. *Hens*—First, Mr. S. H. Hyde. Second, Mr. Davies. Third, Mr. Jas. Dixon.

HARDING (Silver-spangled)—First, Mr. J. Fielding. Second, Mr. James Dixon. Third, Right Hon. Countess of Dartmouth. *Chickens*—First, Mr. James Fielding. Second, Mrs. Pettit. Third, Mr. William Johnson. Fourth, Mr. W. B. H. Potts. *Hens*—First, Mr. W. R. Lane. *Pullets*—First, Mr. J. Davies. Second, Mr. J. Fielding.

POLANDS (Black and White Crests)—First, Mr. James Dixon. Second

and Third, Mr. T. P. Edwards. *Chickens*.—First and Second, J. G. Sugden, Esq. Third, Mr. T. P. Edwards.

POLANDS (Golden).—First and Second, Mr. James Dixon. Third, Mrs. Pettit. *Chickens*.—First and Third, Mrs. Pettit. Second, Mr. J. Dixon. *POLANDS* (Silver).—First, Mr. G. C. Adkins. Second and Third, Mr. J. Dixon. *Chickens*.—First and Third, Mr. G. C. Adkins. Second, Mr. J. Dixon. ANY OTHER DISTINCT VARIETY.—First, Mr. Jeffrey Ashcroft. Second, Hon. C. Finch. Third, Mr. Cam Baker.

GAME (Black-breasted Reds).—First and Cup, Mr. W. Robson. Second, and Archer, Mr. E. Archer. Third, Mr. G. W. Moss. *Chickens*.—First, Mr. J. Stubbs. Second, Mr. W. Hopkinson. Third, Mr. W. Dawson. Fourth, Hon. W. V. Vernon.

GAME (Brown and other Reds, except Black-breasted).—First and Third, Mr. G. W. Moss. Second, Mr. James Fletcher. Fourth, Mr. J. Wood. *Chickens*.—First, Mr. James Wood. Second, Mr. Edward Archer. Third, Mr. G. W. Moss. Fourth, Mr. George Cargay.

GAME (Hens (Black-breasted and other Reds)).—First, Mr. G. W. Moss. Second, Mr. J. P. Smith. *Pullets*.—First, Mr. George Cargay. Second, Mr. J. P. Smith.

GAME (Duckings and other Greys and Blues).—First, Mr. John Dancastr. Second, Mr. John Hindson. Third, Mr. Richard Swift. Fourth, Mr. James Fletcher. *Chickens*.—First, Hon. W. V. Vernon. Second, Mr. John Dancastr. Third, Mr. Thomas Carless. Fourth, John W. Blackburn.

GAME (Black and Brassy-winged except Greys).—First, Mr. James Drewry. Second, Mr. William Dawson. Third, Mr. G. Iiellwell. *Chickens*.—First, Mr. T. Burgess, jun. Second, Mr. W. Dawson. Third, Mr. James Fletcher.

GAME (White and Piles).—First, Mr. J. Camm. Second, Mr. William Hopkinson. Third, G. W. Moss, Esq. *Chickens*.—First, T. H. D. Bayley, Esq. Second, Mr. George Crofts. Third, Messrs. Bullock & Rapson.

GAME (Hens (except Black-breasted and other Reds)).—First, Mrs. T. Goodson. Second, Mr. F. Munn. *Pullets*.—First, G. W. Moss, Esq. Second, Mr. H. Baker.

CLASSES FOR SINGLE COCKS.

DORKING (Silver Grey).—First, Right Hon. Lady Bagot. Second, Mr. George Cargay. Third, Mr. W. Doiby, jun.

SPRING (except Silver Grey).—First, Lady Louisa Thynne. Second, Mr. Edward Piddou. Third, Mr. Joshua Waddington.

SPANISH.—First, Mr. Henry Lane. Second, Mr. David Harding. Third, Captain Heat n.

COCHIN CHINA (Cinnamon and Buff).—First, Capt. Heaton. Second, Mr. Henry Jones.

COCHIN CHINA (Except Cinnamon and Buff).—First, Mr. Cartwright. Second, Miss V. W. Musgrove.

BRADIA (Footed).—First, Chris. Dain. Second, J. H. Craigie.

HAMBURGH (Golden-pencilled).—First, Carter and Valiant. Second, Wm. Kershaw.

HAMBURGH (Silver-pencilled).—First, Rev. T. L. Fellowes. Second, John Martin.

HAMBURGH (Golden-spangled).—First, W. C. Worrall. Second, Jas. Muir.

HAMBURGH (Silver-spangled).—First, John Robinson. Second, Lady Julia Cornwallis.

POLANDS.—First, Mr. J. Dixon. Second, Mr. G. C. Adkins.

GAME (White and Piles, Duckings and other varieties except Reds).—First, Mr. J. Hindon. Second, Mr. J. Fletcher. Third, Mr. W. Kershaw.

GAME (Black-breasted Reds).—First, Mr. N. Grimshaw. Second, Mr. W. Cox. Third, Mr. R. Swift. Fourth, Hon. W. V. Vernon.

GAME (Brown and other Reds, except Black-breasted).—First, Mr. G. W. Moss. Second, Mr. T. Burgess, jun. Third, Mr. J. Fletcher. Fourth, Mr. W. Dawson.

BANTAMS (Gold-laced).—First and Second, Mr. T. H. D. Bayley. Third, Mr. T. W. Hill.

BANTAMS (Silver-laced).—First and Second, Mr. T. H. D. Bayley. Third, Mr. E. Hill.

BANTAMS (White, clean-legged).—First, Mr. T. H. D. Bayley. Second, Mr. H. Lowe. Third, Mr. W. H. Denison.

BANTAMS (Black, clean-legged).—First and Second, Mr. G. Bradwell. Third, Mr. W. C. Wo fall.

BANTAMS (Any other variety).—First and Third, Mr. G. Daft. Second, Mr. C. R. Titterton.

GAME BANTAMS (Black-breasted and other Reds).—First, Mr. Richard Swift. Second, Mr. J. Camm. Third, Mr. T. H. D. Bayley.

GAME BANTAMS (Any other variety).—First, Mr. J. Camm. Second and Third, Mr. H. Hawkesley, jun.

GAME BANTAM COCKS.—First, Mr. Turner. Second, Mr. R. Hawkesley, jun. Third, Mr. Richard Swift.

DUCKS (White Aylesbury).—First and Second, Mrs. Mary Seamons. Third, Mr. J. H. Foster.

DUCKS (Rouen).—First and Third Mr. George Daft. Second, Mr. R. J. Robinson.

DUCKS (Black East Indian).—First, Mr. G. S. Sainsbury. Second, Mr. P. Farie.

DUCKS (Any other Variety).—First, T. H. D. Bayley, Esq. Second, Mr. James Dixon.

ORNAMENTAL WATER-FOWL.—First, Mr. T. H. D. Bayley. Second, Mr. John Morris.

GESE (White).—First, Mr. R. Tate. Second, Mr. George Daft. Third, Mr. W. Kershaw. *Birds of 1861*.—First, Mr. R. Tate. Second, Mr. W. Winterton.

GESE (Grey and Mottled).—First, Mr. J. K. Fowler. Second, Mrs. Blair. Third, W. Lort, Esq. *Birds of 1861*.—First and Second, Mrs. Blair.

TRIFLES.—First, Mrs. C. Bowne. Second, Rev. T. L. Fellowes. Third, Mrs. Blair. *Birds hatched in 1861*.—First, Rev. T. L. Fellowes. Second, Mr. John Smith. Third, Mr. E. Guy.

PHEASANTS (Golden).—First, Charles Sturge. Second, John B. Payne.

PHEASANTS (Silver).—Fryze, G. C. Wright.

PHEASANTS (Any variety).—First, Charles Sturge. Second, John B. Payne.

PIGEONS.

CARRIERS.—First, Mr. E. L. Corker. Second, Mr. McGregor Rake. Third Messrs. W. Sidons & Sons.

ALMOND TUMBLERS.—First and Second, Mr. M. Rake. Mr. Eden.

BALDS.—First, Mr. F. Esquilant. Second, Mr. J. W. Edge. Third, Mr. T. Nipth.

FEARDS.—First, Mr. H. Yardley. Second, Mr. McGregor Rake. Third, Mr. S. Shaw.

JACO-BINS.—First, Mr. J. T. Lawrence. Second, Mr. G. F. Nicholls. Third, Mr. F. Esquilant.

FASTAILS.—First, Mr. G. Goere. Second Mr. G. C. Adkins. Third, Mr. J. W. Edge.

TRUMPFERS.—First, Mr. S. Shaw. Second, Mr. W. H. C. Gates. Third, Mr. C. Felton.

POWERS or *CROPPERS*.—First, Mr. McGregor Rake. Second and Third, Mr. P. Eden.

MOTTLED TUMBLERS.—First, Mr. E. L. Corker. Second, Mr. Jas. Smith. Third, Mr. T. C. Esquilant.

OWLS.—First, Mr. McGregor Rake. Second, Mr. Jones Percival. Third, Mr. Daniel Thwaites.

NUKS.—First, Mr. J. W. Edge. Second, Mr. Jones Percival. Third, Mr. A. G. Brooke.

TURBITS.—First, Mr. E. A. Hargrove. Second, Mr. S. Shaw. Third, Mr. G. F. Nicholls.

ARCHANGELS.—First, Mr. J. W. Edge. Second, Mr. E. A. L. Silvester. Third, Mr. H. Yardley.

BARDS.—First, Mr. Peter Eden. Second, Mr. J. T. Lawrence. Third, Mr. Cam Baker.

BENTS.—First, Mr. F. Key. Second and Third, Mr. Cam Baker.

DRAGONS.—First, Mr. J. W. Edge. Second, Mr. E. A. Hargrove. Third, Mr. E. J. Somers.

ANY OTHER VARIETY.—First, Mr. G. Machin. Second, Mr. S. Shaw. Third, Mr. John Percival.

CROOK'S POULTRY FOUNTAINS AND FEEDING-CAGES.

POULTRY FEEDING-CAGE.

THESE are the best contrivances for the purposes they are intended for.

The fountains maintain a constant supply of clean water by preventing the birds either drinking it with their feet or dung, and the inside of the reservoir can be cleaned without any difficulty, which was a desideratum these fountains are the only ones to satisfy.

The feeding cages are equally effectual in preserving from dirt the food supplied to the fowls. Each bird can only insert his head and neck between the bars; and the tops can readily be taken off from the bottom when cleansing is needed. Both the fountains and feeding-cages are made of galvanized iron, so that they are never rusty, and are very durable. The feeding-cages are as useful for Rabbits as for poultry.

THE POULTRY FOUNTAIN.

PLYMOUTH POULTRY SHOW.—The prizes are liberal, and which is still better, promptly paid. They vary from £3 to 10s. There are various sweepstakes for single cocks; a silver cup in addition for winner in the Game Cock competition; and another cup, in addition to the stakes, for the best pen of Hamburgs. There are also various prizes for Carrier Pigeons and Galvanic Canaries.

NORTHERN COUNTIES POULTRY SHOW.

THE ninth annual Exhibition of the Northern Counties Poultry and Poultry Society was opened Nov. 26th in the market place of Darlington. This Show has long occupied a prominent place among the agricultural events of the North; and we are happy to be able to state that in the present instance there is no falling off, but rather, on the contrary, unmistakable evidences of improvement. In the aggregate number of entries there is this year a marked advance upon all previous exhibitions of the Society. Of the poultry, we believe it may be safely affirmed that such a collection as was brought together has seldom or never been witnessed in the North of England. Several of the most noted breeders of this kind of stock were among the exhibitors, and every class of domestic fowls was numerously and well represented. As an instance of the size and weight of some of the specimens, we may mention that one pen, consisting of a drake and two Ducks, was found to weigh no less than 26½ lbs. The first-prize Geese (two) weighed 4½ lbs., the first-prize Ducks 26½ lbs.; and the first-prize Dorking chickens, No. 38, 24; lbs. The Darlington ought to be the third centre Show of England. Crystal Palace for the south, Birmingham for the midland, and Darlington for the northern counties.

SPANISH BUSH (First, Master Batham, Caverside, Edinbrough, Second, R. Tate, Biffield, Yorkshire. *Chickens*—First, E. Brown, Sheffeld, Second, J. R. Goddard, A dwick Comt, Writington, Bristol, Third—Crock, 12, H-nington Street, London. Highly Commended, S. Cooner, Finswell, Mendon Farm; Major J. Biffith, R. Simpson, West Lelidon; S. H. Hyde, Tanton Hall, Aston-under-Lyne.

DORKING COLOURED—First, Rev. J. F. Newton, Kirby, Stokesley, Second, H. W. B. Berwick, Helmsley, York, Highly Commended, Lev. J. I. Newton; H. W. B. Berwick; T. W. Hill, Heywood, Manchester.

DORKING WHITE—First, G. Hellowell, Wakeley, Sheffield, Second, F. Newburn Jun., Larchfield, Darlington.

DORKING CHICKENS (any variety)—First, W. Dohy, jun., Syston Old Hall, Grantham. Second, J. Bell, The 1-to-Moor, Northalton, Third, Miss Milne, Otterburn, Kelso, N.E. Highly Commended, W. Brookwater, Fritchard Lane, Darlington; H. W. B. Berwick, Helmsley; T. W. Hill, Heywood, Manchester.

COCHIN-CHINA (Cinnamon and Buff)—First, T. Stretch, Marsh Lane, Bootle, Liverpool, Second, H. B. Bewick, Helmsley.

COCHIN-CHINA (other varieties)—First, J. Shortt, Newcast-on-Tyne. Second, J. Bell, Thibald, Highly Commended, T. B. Steel, Lanchester *Chickens*—First and Second, E. Smith, Moleton, Manchester. Third, R. D'Evos. Highly Commended, T. Stretch, Liverpool; H. W. B. Berwick, Helmsley; R. D'Evos, Knarborough; Miss A. Watkin; J. Shortt, Newcastle-on-Tyne.

GAME BIRD-BREASTED—First, H. Adams, Beverley, Yorkshire. See ed. H. Adams, Beverley, Yorkshire. Highly Commended, I. Dodds, Oveden, Halifax, Yorkshire. *Chickens*—First, E. Aikroyd, Darlington. Second, H. Adams, Beverley. Highly Commended, A. Perkins, Belle Vue Cottage, Darlington; T. Dodds, Oveden, Halifax, Yorkshire; W. J. Cope, Ramsley; G. Hellowell, Wakeley, Sheffield.

GAME DUCKINGS (Grey, and Blue)—First and Second, H. Adams, Beverley. *Chickens*—First, J. Crossland, jun., Wakefield. Second, H. Adams, Beverley.

GAME (any other variety)—First, G. C. Whitwell, Kendal. See ed. J. Crossland, jun., Wakefield. *Chickens*—First, J. Fletcher, Stoneclough, Manchester. Second, G. S. Thompson, E. Fethell, York.

HAMELTON (gold and silver-spangled)—First, J. Dixon, North Park, Bradford. Second, W. Froggatt, Wakeley, Sheffield. Highly Commended, R. R. Thip, Moss-searmonth; S. Smith, Northwram, Halifax; A. Nicholson, Wakeley, Sheffield.

HAMELTON (gold and silver-spangled)—First, H. Beldon, Park Cottage, Bradford. Second, J. Dixon, North Park, Bradford. Commended, T. V. Turner, To View, Sheffield. Commended, J. Dixon, Bradford.

HAMBURG Golden-pencilled—*Chickens*—First, H. Beldon, Park Cottage, Bradford. Second, F. Harby, Quarry Gap Road, Lister Dyke, Bradford. Commended, J. Dixon; W. Froggatt, Wakeley, Sheffield; S. Smith, Northwram, Halifax.

HAMBURG Silver-pencilled—*Chickens*—First, H. Beldon, Park Cottage, Bradford. Second, J. Dixon, North Park, Bradford. Commended, G. Hellowell, Sheffield.

HAMBURG (Gold-spangled)—*Chickens*—First, W. Froggatt, Wakeley, Sheffield. Second, J. Newton, Silton, Leeds.

HAMBURG (Silver-spangled)—*Chickens*—First, H. Beldon, Park Cottage, Bradford. Second, J. Dixon, North Park, Bradford.

FOLANS (Black with White Crest)—Prize, J. Dixon, North Park, Bradford.

POLAND (any variety)—First, H. Beldon, Park Cottage, Bradford. Second, J. Dixon, North Park, Bradford. Commended, J. Dixon. *Chickens*—First, H. Beldon, Park Cottage, Bradford. Second, J. Dixon.

ANY OTHER BREEDS (any variety)—First, R. Tate, Driffield. Second, A. Cattle, York. Third, T. D. Chambers, Wakeley, sheffeld.

BANTAMS (gold and silver-laced)—First, J. Dixon, North Park, Bradford. Second, T. H. D. Bayley, Ickwell Hill, Biggleswade, Beds. Highly Commended, E. Hutton, Pussey, Leeds.

BANTAMS (White)—First, R. Est. Driffield. Second, T. H. D. Bayley. **BANTAMS** (Black)—First, R. Est. Driffield. Second, Hutton, Pussey, Leeds.

GAME BANTAMS—First, T. H. D. Bayley, Second, G. Bentley, Kirk-tail, Leeds. Third, J. Croft, Nantwich.

DUCKS (Any variety)—First, Mrs M. Seamons, Hartwell, Acle-hurd, Darlington. Second, E. Tate, Driffield. Highly Commended, G. Pease, southend, Darlington; S. Burn, Whitby.

DUCKS (Rouen)—First, R. Tate, Driffield. Second, T. H. Barker, Houghton, York-shire. Highly Commended, Miss Wetherill, Acle-hurd, Darlington; T. H. Barker, J. Dixon, Bradford; J. Craw, Jedburgh, N.E.; J. U. Somers, Jedburgh, N.B.

DUCKS (any other variety)—First, J. Dixon, Bradford. Second, E. Hutton, Pussey, Leeds. Highly Commended, G. Pease, Southend, Darlington. **ANY OTHER BREEDS** (any variety)—First, Mrs. M. Seamons, Hartwell, Acle-hurd, Darlington. Second, Mrs. M. Seamons, Hartwell, Acle-hurd, Darlington. Highly Commended, Mrs. M. Seamons; J. Dixon; T. H. D. Bayley; J. Holme, Knowley, Prescot; R. Tate.

GRAYS—First, R. Tate. Second, G. Pease, Southend. Highly Commended, Mrs. Milner, Thirsk; *Geese*—First, Mrs. M. Seamons, Hartwell, Acle-hurd, Darlington. Second, Mr. Sturde, Galsborough. Highly Commended, Mrs. Milner, Thirsk; J. Carr, Jedburgh, N.B.; B. Tate, Driffield.

TURKISHS—First, G. Pease, Southend. Second, E. Guy, Eaton, Grantham. *Pouls*—First, R. Tate, Driffield. Second, Rev. T. L. Felowes, Acle-hurd, Darlington. Highly Commended, Mrs. A. Johnson, Viewly Hill, Long Newton; G. Pease.

GUINEA FOWL—Prize, R. Tate, Driffield. Highly Commended, F. Newburn, jun., Larchfield, Darlington.

DORKING WHELTERS (any variety)—First and Second, H. W. B. Berwick, Helmsley. (No. 38 exhibited by William Gray, Darlington, being immediately disqualified as "silly old hens, and a palpable falsehood, which ought to be exposed).

GAME PHEASIS (any variety)—First, J. Crossland, jun., Wakefield. Second, E. Aikroyd, Darlington. Commended, T. Dodds, Oveden, Halifax.

SINGIE DORSET'S COCK (any variety)—First, E. Smith, Middleton, Manchester. Second, H. W. B. Berwick, Helmsley.

SINGIE GAMB COCK (any variety)—First and Second, H. Adams, Beverley. Third, J. Fletcher, Stoneclough, Manchester. Commended, J. Firth, Halifax; J. R. Rodbard, Writington, Bristol; E. Hutton, Pussey, Leeds; G. Hellowell, Sheffield.

SLEEPSTARS—*Game Cock*—First, J. Firth, Halifax. Second, N. Grimshaw, Penile Forest, Bar-lez, Third, A. Hodgson, Hillingworth, Halifax. Commended, R. Tate, Driffield. *Game Lancers*—First, J. Firth, Halifax; J. R. Rodbard, Writington, Bristol; E. Hutton, Pussey, Leeds; G. Hellowell, Sheffield.

PIGEONS

CARLETON COCK—First, J. W. Wooler, Holywell, Heighington. Second, J. Shortt, Newcastle-on-Tyne. Commended, W. Cannon, Bradford; A. L. Silvester.

CARLETON HEN—First, W. Cannon, Bradford. Second, J. Shortt, Newcastle-on-Tyne. Commended, F. Newburn, jun., Larchfield, Darlington.

FOWLT COCK—First, F. Newburn, jun., Larchfield, Darlington. Second, W. Cannon, Bradford.

FOWLT HEN—First, F. Newburn, jun., Larchfield, Darlington. Second, W. Cannon, Bradford.

ALMOND TUMBLERS—First, W. Cannon, Bradford. Second, A. L. Silvester, Birmingham.

TUMBLERS—First, W. Cannon, Bradford. Second, J. Percival, Birmingham.

FAVANTS—First, E. Brown, Sheffield. Second, T. Ellington, Woodmansey, Bevelay. Commended, W. Vaughan, Cleveland Lodge.

TREAZURES—First and Second, F. Newburn, jun., Larchfield, Darlington. Commended, J. Wilson, Darlington; E. Newburn.

BARDS—First, W. Cannon, Bradford. Second, J. Entwistle, Chapel Allerton, Leeds.

JACOBS—First, W. Cannon, Bradford. Second, E. Smith, Birmingham. Commended, W. Vaughan, Cleveland Lodge; T. Ellington, Woodmansey, Bevelay.

TURBIS—First, J. Vaux, Durham. Second, J. Entwistle, Chapel Allerton, Leeds.

OWES—First, W. Cannon, Bradford. Second, J. Entwistle, Chapel Allerton.

ANY OTHER NEW OR UNUSUAL VARIETY—First and Second, F. Newburn, jun., Larchfield, Third, Mrs. J. W. Wooler, Holywell, Heighington. Fourth, E. A. Hargrove.

Judges for Poultry and Pigeons, Messrs. Smith and Bird.

MR. TATE AGAIN.

SEEING in your Journal of the past week a statement of Mr. Tate's behaviour towards the Secretary of the Plymouth Poultry Show, I am induced to acquaint you of a transaction with myself and the above-named person. In your Number of the 17th of September last, an advertisement of Mr. Tate's appeared, and amongst other birds enumerated was a pen of "Brahma chickens," 21s., have taken "five first prizes" this season. I wrote him to know if he still held the birds I would have them, and on hearing would forward a post-office order for the 21s. Getting his reply in the affirmative, I sent the order, and had in return two pullets and a one-year-old cock, also receiving a letter by post stating the cock had died. Such might have been the case, but I think Mr. Tate should have given me this information before he set off the birds, as I should certainly have countermanded, "the chickens" being expressly what I wanted. I have exhibited the birds, and the Judges never passed the slightest commendation on them. On receiving the birds I really doubted the truth of the advertisement, and subsequent matters tend to confirm the same.—F. BAILY, *H. S. Calve Poultry Show*.

INQUIRE THE PRICE BEFORE YOU SEND YOUR POULTRY TO LADENHALL MARKET.

I RECENTLY sent two hampers of fowls to a salesman in Lendenhall Market. Many of them were this year's birds, and

weighing 9 lbs. a-couple. I inclose his list of prices which he had the courage to send me. In your next impression please give your opinion.—T. V.

Leadenhall Market, 18th November, 1861.

Nov. 7th—4 Chicks	20	4	0
12 Hens	0	14	0
Nov. 14th—12 Fowls	1	0	0
	1	18	0
Comm. 2s., paid, 3d.	0	2	3
	1	15	3

[Without knowing what condition they were in we cannot give an opinion upon the prices; but if the hens were old 1s. each would be as much as they were worth. At this season fowls are at about their lowest price in London. You obtained 3s. 4d. per couple for yours, and they are retailed just now at 4s. 6d. per couple. We have inserted your communication as a warning to our readers, not because we are able to say that you had a good ground for complaint.—Eds.]

APIARIAN NOTES.—No. XIII.

DURING the last few months, so much has been written on apian matters in the JOURNAL OF HORTICULTURE, by well-qualified correspondents, that I have rather refrained from using my own pen until there should appear a falling-off in contributions to this very interesting portion of its pages. And here let me say how I wish that the old title of THE COTTAGE GARDENER had been retained unchanged. It appears to me much less easy to sit down and indite a gossiping article on bees for the page of a periodical, with the somewhat formidable title of JOURNAL OF HORTICULTURE, than that it used to be for the weekly serial with the less pretentious name of COTTAGE GARDENER. But at the same time, I must in common with all its readers, bear testimony to the great improvement which it has undergone since the change; and in unison with the readers interested chiefly in the "Poultry, Bee, and Household Chronicle" department, I must express my gratification that the writers on apian subjects are so well encouraged to take up their pens and give to its readers the results of their experience; and also that inquirers are so freely permitted to seek information either from the Editors, or the numerous correspondents.

DOES THE SUPER BECOME THE STOCK-HIVE?—I have been a good deal surprised at the exception which has been taken to the reply to "A. W.," in a late Number, by certain correspondents, who maintain that the super will invariably become the stock-hive. Such an any rate is not in accordance with my experience. I have too much respect for the opinions of practical men, such as "A. RENEVSHIRE BEE-KEEPER," and your Ayrshire correspondent, to state this as my opinion in such direct opposition to their's without having duly considered the subject. Every apian should know that bees will not always follow a certain line of conduct. A hive may be worked one season on a particular plan with perfect success; the following under precisely similar arrangements, so far as the owner is concerned, a complete failure may be the result. Take one instance—the year before last my adjuster-hive stored in its super fifty-three pounds of beautiful honey, with not six cells of pollen and no brood whatever. The summer previously, thirty pounds were taken from the same hive, and bees in the same way and in the same condition. This summer, on the contrary, the bees after partially filling the super with combs converted it for a time into a breeding compartment, constructed a great number of royal cells therein, and threw off two very fine swarms. Honey was as plentiful at that time as in either of the previous seasons, and I should much like to know why the results varied so vastly. I will not, therefore, commence by stating that the super never becomes the stock-hive; it may occasionally be so converted, but I fearlessly assert that such conversion is contrary to the general law. If such were the case, I do not think we could ever expect to take off our well-filled, broodless, supers of honeycomb, for they would in all cases be transformed into mere breeding compartments.

To avoid misconception, I will state that I consider to be the question at issue between us. We have two stocks equally well furnished with combs; No. 1, queenless, is placed on No. 2, having a queen. Which will become the stock-hive? The queen may, and most probably will, ascend and lay a great number of eggs in the combs of No. 1. As these are hatched out the cells will be filled with honey; and I think in at least nine

cases out of ten, if the two hives are separated in the autumn, that the queen will be found in the lower hive. It is but a question of time. It is a well-known law in the economy of a hive, that the honey is stored in that part of it furthestmost from the entrance, and it matters not whether the hives used be placed one above another or collaterally. I have seen a unicorn-hive on Dr. Bevan's plan, having the entrance at one end instead of in the centre as he gives it, where the honey was stored in a triangular shape chiefly in the upper part of the furthest end, the breeding part, with the mass of the population being confined to the lower part nearest the entrance. The very first year after I commenced bee-keeping (about fifteen or sixteen years ago), early in June I purchased of a cottager a strong cottage-hive, which must within a few days, if left undisturbed, have cast a swarm. This was removed the same evening a distance of two miles to my town garden. Having a straw hive filled with empty combs, by using the two boards described by Taylor in the manual (sixth edition, page 80); it was placed so that the bees had to pass in and out through the spare hive. In a very few weeks I took away the inner or what had been the stock-hive, with thirty-five pounds of honey and not a cell of brood. The second hive, equally heavy, was crammed with brood down to the very bottom of the combs.

Some may say that this does not bear upon the point, that it is only a case of collateral working and not of storifying. But, although considering it does apply to the matter under discussion, I can give an instance of a storifying-hive, one out of many that have come under my notice, which I bring forward chiefly because it is one of which the actual circumstances of the case are better remembered by me than most others.

The year 1860 was the worst for bees I have ever known, and few hives worked at all in supers, with the exception of constructing a few empty combs. On one of my stocks, a flat-topped straw hive, a good-sized octagon-super was filled with combs and sealed honey, weighing about 25 lbs., and in every way adapted for a stock-box. This was taken off in September, but on inspecting the lower, or stock-box, in which were the bees, no honey was to be found, so the super was returned to the hive. One reason which actuated me being, that I wished the Stewarton-octagon to become the stock-hive. In the spring, having a weak stock which it was desirable to strengthen with a little brood, I inspected both the super and the lower stock-hive. In the former was found a considerable quantity of brood, but the queen was in the lower hive, and then breeding there; all the bees quickly leaving the super for the stock-hive. The super was then placed as it was, under the hive which required strengthening; but in a day or two, seeing that the bees were not numerous enough to cover all the brood, and fearing that if left so it would be sacrificed, it was again placed on its original stock. On a further inspection about three weeks afterwards, the brood was found to be all hatched out and very few bees in it. I, therefore, removed it altogether, and soon after placed an empty Stewarton-super on the same stock, which in due time was taken off with 25 lbs. weight of honey. In the foregoing instance I should not have been surprised if the super had become the stock-hive, as the combs were new and well formed with stored honey; whereas those in the stock were some years old, and so far as I could discover without any honey. The bees took down gradually what honey was required for their consumption, as there was not a great deal left when finally removed. I must again state, that the answer given to the query of "A. W.," would, in my opinion, be found to be correct in the majority of instances. In cases where the super should be made the stock-box, I should conclude that the bees were led thereto by certain influences, such as considerable superiority of combs, &c. As I did not intend to have extended my observations on this topic to so great a length, I will defer to a future chapter of "Apian Notes," the consideration of other matters which have attracted my notice, and my experience as a bee-keeper during the past season.—S. BEVAN FOX, Exeter.

BEEES AND THE ART OF QUEEN-MAKING.

IN the August number of "Good Words" appears an article under the above title from the pen of the Rev. William Leitch, D.D., Minister of Manimail, Fifeshire, and last year appointed Principal of Queen's College, Canada, in which a new theory is

* Good Words, a Magazine for all the Week. Edinburgh: Strahan. London: Groombridge.

propounded with regard to the cause which operates in the production of what are called "artificial queens," during which process the marvellous effect is produced of converting a worker egg or young grub into a perfectly developed queen.

Before entering upon the question as to whether Dr. Leitch has hit upon the true cause of this phenomenon, we may first advert to two or three instances in which he is so decidedly at fault, as to raise some doubts in our mind as to whether he has brought his whole power of observation to bear on the subject, or whether the paper may not be regarded as an exposition of views somewhat hastily entertained, and which it is not unlikely may be either greatly modified or entirely discarded after more mature investigation.

Speaking of the manner in which a queen bee first inserts her head before depositing an egg in a cell, our author says, "she never omits the depositing of an egg if she has previously inserted her head." This assertion is so contrary to the fact that, when a hive gets pretty full of brood, honey, and pollen, it is by no means unusual to see a queen insert her head in a dozen cells, or even more, before she finds one in which to lay an egg.

There is, also, an extraordinary mistake with regard to the average duration of life in the workers, which is stated to be "only six weeks." It has been pretty well ascertained that the life of a worker bee does not much exceed six or seven months, from which, of course, something must be deducted on account of accidents, if we are to arrive at an average; but to place it so low as six weeks is altogether preposterous. This error leads, also, to another, which is, that whilst a queen bee lays eggs "at the rate of an egg per minute," she does "nothing more than keep up the balance between life and death." Most apian observers are aware that whenever a queen bee lays eggs at the rate of nearly 1500 a-day the population rapidly increases, which increase (if not put a stop to by swarming), continues until it is checked by the mortality of autumn, and the diminution and ultimate cessation of breeding which then takes place.

Again, after stating with perfect correctness that the queen bee "does not put on the airs of a monarch, for her duties are simply maternal," Dr. Leitch contradicts himself by speaking of the workers as "the servile class" and remarks on the marvellous power which changes "a slave into a queen."

Our author then asks, "What is there in this new cradle (a royal cell) to account for the transformation? It cannot be the size, for the queen, at the time she comes forth from her cell, is hardly larger than a worker bee, and the cell must be accurately fitted to her body." Now this is all wrong, and calculated only to mislead; the queen when she first issues from her cradle is really very much larger than any worker when it first appears; and the cell, so far from being accurately fitted to her body, is so large that if it be shaken near the ear, prior to the young queen's exclusion, she may be both felt and heard to strike against the sides of her prison.

We now come to the Rev. Principal's theory with regard to the production of artificial queens, which we give in his own words. After noticing the power which bees possess of increasing the temperature of any part of their hive by an accelerated respiration, Dr. Leitch says:—"Viewing this power in connection with the insulation of the queen's cell, we have a clue to the mystery of development. We soon see why the bees should be at so much pains to drag the royal larva out from the midst of its companions and place it in an insulated position, where a special temperature may be applied. Were the royal larva allowed to remain in its original position, a higher temperature could be applied only to the end of the cell, and the end of the cell is so small that it would be difficult to apply a differential temperature to it. To meet this difficulty the queen is made to slide out of her old position into a new one, where she can be completely surrounded by the hatching bees, and have an elevated temperature applied to all parts; and, when you look into a hive, you see the bees constantly clustering all over the insulated cell. The warmth is applied, not as in a footpath to the extremities, but to the whole body, which is immersed in a medium of an elevated temperature. The surmise that temperature furnished the clue to the secret was confirmed by actually testing it; small thermometers were inserted into the hive, one in contact with the queen's cell, and others in different parts of the comb, we found that the difference of temperature bore out our hypothesis, that a higher temperature was steadily applied to the queen's cell. The inference is then legitimate that temperature, if not the cause, is one of the causes, which account for this, the greatest marvel in insect life. There may be other

causes combining to produce the result; but that special temperature is one essential element our experiments conclusively established."

As the Rev. Principal does not particularise any experiments beyond thermometrical observations, we may be excused for doubting whether these are quite so conclusive as he imagines, as well as for suggesting that it is just possible that he may have mistaken effect for cause, since it by no means follows that because the process of queen-raising is generally attended with an increase of temperature, the insulation of a queen's cell or even a special temperature is absolutely essential to its success. In frame-hives especially we have often found queens hatched out of cells which were so placed as to render it impossible for the bees to cluster all over them, whilst the general position of queens' cells on the edges of the combs, and, therefore, in the coldest parts of the hive, is such as of itself to raise a doubt as to the correctness of the new theory.—A DEVONSHIRE BEE-KEEPER.

BOTTLE-FEEDING FOR BEES.

SEING the other day Messrs. George Neighbour & Son's new bottle-feeders, at their Glasgow agents, reminded me of an old score I had to settle up with that "Main Pillar" of your valued bee-corner, "A DEVONSHIRE BEE-KEEPER," in justice to whom, as well as this plan, it was my intention to have alluded long ago.

As there are few apianists so happily situated, but must have recourse to feeding at some time, or lose their stocks; and as nearly every one has some particular scheme of his own, from the ready soup-plate of the cottager, with its floating straws, up to the polished rosewood or mahogany octagon, with its glass top, and numerous eeteras of his more aristocratic brother; so that bee-feeders are about as plentiful as bee-keepers.

With the opening Number of your new series, I commenced a somewhat lengthy account of the "Bee-hives and their Appurtenances" of my own apiary, and naturally enough as feeders came round, described in No. 6 the modes I employed, mentioning the subsidiary piece "The Bottle" then held, being only used to supply a weak, or stimulate a stubborn stock.

This plan, although known and practised more or less in these northern regions, was new in the south, till your Devonshire correspondent, meeting with it in M. Hermann's work, tried and recommended it to your many apian readers; and, consequently, being quite "new fangled" with the system, was ready to take up the cudgels on its behalf, and in the following Number came down upon me for styling it "a slow process," besides asseverating as strenuously as any thirsty Hibernian, that out of the bottle came "never a drop," informing us at the same time that he had supplied his favourites the previous autumn with a couple of hundredweight of food through its instrumentality.

This high recommendation from so trustworthy an authority caused me, my stocks at the time being at a low ebb, to try it on a larger scale; and when I tried it with populous stocks, found it was not such a slow process as my previous experience with weak ones led me to believe; still it is slower than any of the modes previously described—indeed slowness is its only defect, otherwise for cleanliness, saving of excitement, or disturbance to the hive, I can most cordially throw in my testimony with that of your esteemed correspondent that it is decidedly in advance of any other I have yet tried.

I had ocular demonstration of the dropping. Many a time have I, after withdrawing the cork from a fanishing family in a straw hive, watched the food get on their coats and combs, and with their extended little proboscis lick it up. I also recollect once getting an accumulation of food that had dropped on the board of a defunct colony which perished during a long frost; still upon using a finer net, doubled, I found beyond a single drop or two, on first reversing the bottle, your correspondent was perfectly right as to what he said of the exemption from leakage.

To aid in accelerating the emptying of the bottle, I have tried various plans, some of which for the benefit of your readers interested in bottle-feeding, I will now describe.

There is nothing intrinsically slow in the system, the deficiency being in the small surface of net exposed to the bees, and the limited number that can get room to draw out and remove the food from the little space—say three-eighths between the bars, by cutting with a brace and bit an inch-and-a-quarter hole

between the two central bars, so that the entire month of the bottle could be introduced, I found it was emptied in half the time; still the bees between the two particular combs, above which the bottle was placed, were only employed, their neighbours of the adjoining ones, from inability to reach and assist in appropriating the food, being at the same time in a state of inaction, so that several might be employed at one and the same time on a bar-and-slide hive.

To obviate this in all the straw hives I have had made this season, the work was begun on a circular six-inch ring of red pine (Fig. 4), in the outer edge of which a groove is run for the more ready retention of the first straw band out of it, it is very unlikely to start; but it may be further secured by a small nail or two before the second is added.

Round the inner edge of central four-inch ring is left a projecting quarter-inch check at bottom to receive the bung (Fig. 3), upon which it rests; and, consequently, fits flush above and below. Through it a circular $1\frac{1}{4}$ inch aperture is drilled, so that a small quantity of food might be administered. It is stopped like those in my frame-hives by an inch-and-a-quarter piece of half-inch wood set in a little bit of cotton cloth for its more ready extraction. The main use of this bung (Fig. 3), is to prevent the bees filling the ring space with comb during the working season, when the hive is to be fed. Autumn and spring it must be withdrawn altogether, and the block (Fig. 2), with an inch-and-a-quarter aperture, and the check to fix and steady it set on it is partially hollowed inside, which with the ring space allows a larger number of bees to congregate, and ready access to ascend and descend in three spaces between the combs. Although not seen in sketch, short pieces of bars with comb attached, or bits of Woodbury-bars, are fixed under the ring from back to front to regulate the comb-building.

Fig. 1 is the clear conical soda-water bottle I feed with, on which the straw-hackle sits quite jauntily.

For flat-topped hives I have the block turned out of the solid in a piece, with a five-inch square three-eighths of an inch thick, like a stand, corner view of which is seen in sketch (Fig. 5). This enables it to be fitted into a little half-inch frame fixed on the hive, kept secure with a couple of small brass bars; so secured it is seen in sketch No. 6.

Surely, the inventive genius of the High Holborn concern was asleep when Messrs. Neighbour having their hand in, could not, in these days of cheap glass and art-design, hit upon something better than a mere stumpy bottle, the principle being equally applicable to another shape. Suppose we take as a more graceful one—for instance, the Bell, and as the good old adage says, "That every tub should stand upon its own bottom," why not every bee-feeder? This form can do it (Fig. 7), supersede the necessity for the supporting

to secure when on, to the board in dome-shaped hives. As bar-hives are now so much in vogue, why not for them vary a little?

block, and as effectively exclude wasps and robbers. Round the central-one-and-a-quarter-inch hole I would have a projecting half-inch rim, and in the upper part of it a slight indentation or groove, in which the tying thread would rest. Then, charged and netted it was ready for insertion into the one-and-a-quarter-inch aperture. There might also be four little holes in the stout rim for passing a cord through, as in Fig. 8, by having a long three-eighths slip, same projecting half-inch rim and groove, it could be slipped in between the bars; and, if we bee-keepers could agree upon a uniform breadth of bars, and width between, then there might be two or three of them to feed between them as many combs at one and the same time.

FIG. 8.

In designing a new bottle-feeder, the block might be made to serve a much more important object than that of a support. By increasing the feeding-mouth of No. 7 to nearly the width of the bottom of the bell, resting it in a quarter-inch check on its top, in which the perforated zinc would be previously placed, or by increasing the thickness of the straight edge of outer rim, it could be altogether open, the net tied in a groove in said edge. By either of these modes a considerable body of bees would gain access from the space between the bars to the under side of zinc, and draw out the food from the large surface of net quicker than by any other plan; and, supposing the block be also of glass, a nice "bead" on its outer edge, from its thickness—say, $1\frac{1}{2}$ inch or 2 inches, it would both lie solid, and the feeding be seen, besides forming a handsome appendage to the bell.

An old bee-keeper to whom I recommended the system of feeding, thought he saw he could improve on my design, by having the upper portion to come off as a lid, forgetting all the while atmospheric pressure, and did not discover his mistake till charging it for the first time, saw the food run in a stream from the entrance of his hive. By using linen instead of net he tells me he now uses it.

I find the bees, generally, should the bottle be left on any time, after it is emptied, for the sake of the saccharine matter with which the net is saturated, eat it through. The zinc prevents this, although it protracts the removal of the food: still, I find the bottle (No. 1) can be emptied by a fair stock twice in twenty-four hours, equal to 2 lbs. weight of food converted out of 21 ozs. sugar.

From the above voluminous hints I hope to see produced a really superior feeder on the bottle principle; and should the parties get "honourable mention" at the coming Exhibition of 1862, expect as compensation for the piracy, they will send half-a-dozen north as a pattern to—A RENFREWSHIRE BEE-KEEPER.

[We believe that Messrs. Neighbours' simple feeding-bottle and block can readily be made to fulfil every purpose that would be answered by the apparatus which has been so ably sketched by our correspondent, and are far from blaming them for confining their attention to a bee-feeder, which should be at once effectual and inexpensive. All intricate forms being difficult to manufacture, would be costly in production, difficult to keep clean, and troublesome in use.]

FIG. 5.

FIG. 6.

"A RENFREWSHIRE BEE-KEEPER" we think is still somewhat at fault with regard to the assumed "slowness" of bottle-feeding. We have, this season, administered to our bees above 6 cwt. of liquid food entirely by means of the bottle, and we can confidently state that it is anything but a "slow" process. A strong stock will readily appropriate 5 lbs. per diem from one of Messrs. Neighbours' feeding-bottles, and through perforated zinc. We believe this to be quite as rapid a rate as is consistent with economy and the well-doing of bees. These results are in part attributable to our feeding through a two-inch aperture, in what our correspondent did not approve of. His slow rate of progress is doubtless owing to what we consider an inconvenient arrangement of slides.

By simply inserting a piece of half-inch wood with a four-inch circular aperture between the top of a bar-and-slide hive, and the block of the feeding-bottle, three sides may be partially withdrawn, and the appropriation of the contents of the bottle will be proportionately accelerated with dome-shaped straw hives. All that is necessary is a two-inch central aperture and the exercise of some little ingenuity in affording a steady support to the feeding-bottle and block.

The meshes of the net we use for feeding are about one-sixteenth of an inch in diameter; and, if "A RENFREWSHIRE BEE-KEEPER" will fill his soda-water bottle with pure water, tie it down with only a single thickness of net of this description, and then invert it, he will at once, we think, discard the notion of bee-food dropping from the bottle after the first rush consc-

quent on turning it over has subsided. This may be allowed to fall into the hive, or into a jug held to receive it; and, in either case, will produce no ill consequences.]

THE CANARY AND THE BRITISH FINCHES

(Continued from page 158.)

THE BREEDING-CAGE.

The cage in which Canaries or their mules are bred should be much larger than those for single birds. Common breeding-cages made of thin deal, the top, back, and ends being boarded, and the fronts only of wire, are sold very cheap at the London cage makers; a tolerable one costing about 3s. 6d. These cages are fitted up with the general conveniences; but are, I think, too small for any but the smaller varieties of birds.

A good size I consider to be about 3 feet long by 2 feet high, and 18 inches deep from back to front, close-boarded at the top, bottom, back, and ends. The whole of the floor should have a slide or false bottom to draw out in order to clean the cage, and contain sand, so necessary to absorb the moisture from the dung, and keep the cage clean and dry; as also for the birds to pick out the smaller particles of grit which they eat to assist digestion by grinding the hard food in their gizzard.

The roof of the cage I prefer highest in the middle, and slanting to both sides, which will throw off the rain if it out in a hasty shower; and it is always beneficial to hang the birds in the open air when the weather permits. The middle of the roof being the highest, allows the bird to stand erect on the upper perch, which perch at the same time is rather higher than the nest-box; and this is of much importance, as the birds naturally select the highest part for roosting. It will often prevent their sleeping on the edges of the nest, which habit causes the accumulation of dirt, and often of insect vermin, when it should be kept scrupulously clean. It is best to provide two nest-boxes for each pair of birds, and these may be square boxes placed on a shelf, as seen in the accompanying sketch; or they may be suspended at the back of the cage, in which latter position it is advisable to make the boxes rather deeper than ordinary; and a roof or cover like the roof of a Swiss cottage makes them more secluded. The seed-drawer is placed under the breeding-shelf, or, still better, to keep the seed free from dirt in a trough outside at the end of the cage, so arranged that the bird can easily reach it, but not walk over the trough so as to dirt it in. A partition to divide off a part of the breeding-cage is very useful on many occasions—for instance, it often happens, especially in mule breeding, the cock becomes mischievous and will eat the eggs, or peck the young ones, in which case he may be put into the partition; and it is better that he should be opposite to the nest than that he may see the hen, than under it, as is frequently the case. This partition may be made to draw out, so that when not in use the birds may enjoy the whole of the cage; it is also used to place the young birds in when they have left the nest, the old ones still feeding them through the bars; for, as the hen sometimes lays again before they can thoroughly feed themselves, they are apt to crowd into the nest and spoil the new eggs, or the hen will often pull out their feathers to line her nest with, which much disfigures them. Tin pans are placed in both compartments of the breeding-cage, in which the bread, egg, and mawseed are put for the old birds to feed their young ones on, as also for the young ones to begin to feed themselves on before they learn to crack the hard shells of the common Canary seed.

Water is given in the common glasses or "bird-boxes," and the birds put their heads through a hole to reach it. A better form of glass or "fountain" is the high sugar-lard kind of bottle, with a foot or lip which enters the cage, and from a small opening in which the birds can drink. The door being in front the bath is easily suspended over the open doorway; and frequent bathing is much enjoyed by the birds, and conduces much to their health.

Green food may be strewn on the bottom of the cage, and this should be fresh; a bunch of seedy ground-sell, &c., may be put in a gallipot, with a little water to keep it fresh, and stand on the floor of the cage; a lump of mortar containing a small quantity of salt should be placed in one corner of the cage for the birds to peck; or, some use a bone of the cuttlefish instead.

The materials for nest-building are usually placed in a small net and suspended in the cage; or, better perhaps a small rack outside the cage, so that the birds can draw the pieces through the bars, complete the fittings of the breeding-cage.—B. P. BARRIST.

OUR LETTER BOX.

DORINGS IN CONFINED SPACE (*A Farmer's Wife*).—Your room 12 feet by 6 feet, will do you well for roosting and laying in, but they must have a run. Can you not enclose a space with a partitioned wire for them communicating with the room? The larger the space the better. Or cannot you have all the other fowls confined for half the day, and during that time let the Dorings have the full benefit of the farm yard? Let the seven hens with the cock from Lady Vernon's estate, and put the other cock with Dorking hens from some other yard. Feed on a stiff mash of ground oats or ground barley, twice daily, and let them have plenty of green food. Have at least 2 inches of sand and limy rubbish on the floor. Buy our "Dorking Book for the Market," you can have it free by post for seven penny stamps. You will find plenty of useful information in it. Write again if you need our advice.

FEATHERS OF BLACK GAME COCK (*F. B. C.*).—A Black Game cock should have no mottled nor any other mixture of colour in his feathers. He would be disqualified by it.

VALUE OF FEATHERS (*A Dorking-keeper*).—We cannot tell you the exact value of the poultry feathers, as they vary in value. Good fowl feathers average about 4d.; Ducks' and Geese's tail feathers 3d. The feathers of very young birds are worth less. As they carry in them are very valuable if they are quite black and very glossy. We need hardly tell you the Duck's feathers must be kept quite separate from any others.

COENUS-CHINA PELLETS' LEGS (*Heml*).—Clematis-rooted pellets are worthless for everything except to lay eggs. They must be rejected as unripe.

CANARY AND BELFISH MULE (*A Worcester Antiquary*).—Mr. Reichard has got the possibility beyond doubt by stating the fact of a cock Belfish having bred with a hen Canary; but I believe it is very difficult to get them to pair, consequently such Mules are very rare. If you intend to try a cock Canary with a hen Belfish, you will have to have them in the same cage, as it is still so difficult to induce the wild species to sit in confinement.—B. P. BARRIST.

MULT DWAY.—B. E. W. resides at Kennington, and wishes to know the place nearest his residence where he can obtain malt dist or conds.

RABBITS FOR MARKET (*G. J. N.*).—None are superior to a large breed of the common variety.

GOAT MANAGEMENT (*A L.*).—In No. 5, of our new series, at pp. 60 and 62, you will find all that we know upon the subject. We shall be obliged by any of our readers stating the results of their experience in Goat-keeping, feeding, &c.

AN OVERSIGHT (*A North Devonshire Breeder*).—The communication to which you refer to birds is nearly a month before it appeared, and the corrections subsequently requested by its author, which included the omission of the fact as to which object, were forgotten by us, owing to the delay in printing.

BAR AND SLIDERS (*A. Johns*).—The upper portion of all my flat-topped hives are covered entirely with bars and slides, thereby rendering superfluous the thick cover-board, seen raised in sketch No. 8, my series. The 12 inch bars are 1/2 inch thick, and cut out of similar lengths with the usual dimensions of hive cover-board bars, and fitted into them by a partition being cut from the under side of the board equal to the thickness of the wood composing the front and back, and as far as the lower side of the cover-board, which 4 bars are fitted into. Therefore, instead of the cover-board, the bars and slides are fitted. The top of the bars. The slides working in the bars keeping them three-eighths of an inch apart. The end window in the said sketch is objectionably showing only one side of the cover-board, probably behind; and the five long lines in the cover-board in front. Shall the above description not prove sufficiently plain to your correspondent's better plan, as he does not wish to order a full set of STOWARTON'S, would he write to Mr. Wm. Langshaw, Stewarton, for a honey-box or two. These would serve as handsome and useful covers for 5 or 6 flat-topped hives, and at the same time show on each side by the bars and slides are fitted. The bars in these are, however, 1 1/2 inch broad for the facility of getting up massive honey-combs.—A. KEMPERVILLE BEE-KEEPER.

QUANTITY OF FOOD REQUIRED—DOORING PELLETS LAYING (*An Old Subscriber*).—It is quite impossible to state any quantity of food as sufficient for a number of birds, it depends there is much more that they arrive at a certain time of the season; and the quantity of food they require will be allowed for no waste, and in most places as much is wasted as is given. If they are fed by hand, and only so long as they run after, and, therefore, really want food, they will not eat more than two-thirds of what is put per week. Dorking pullets hatched in April should lay in December.

COENUS AND OTHER FOWLS (*Corbin*).—Coenus are good sitters, but they are not so good mothers; they lay very few eggs, so they would be best to lay again at the end of their weeks. If you were to buy 50 common hens for sitting, you have more certainty they would be broody at the time you want. There is more dependance on Coenus for early sets than any other breed. You should not have less than two cocks for twelve hens. Coenus and Coenus are the best winter layers. Dorkings are the best hot-weather, and the most adaptable.

LONDON MARKETS.—DECEMBER 2.

POULTRY.

There is a great supply of everything at market, and no trade. Game is a perfect article, and can hardly be sold at any price if we except Partridges, which are becoming scarce, as they always are at this season of the year.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-four years, the average highest and lowest temperatures of these days are 45.7° and 33.6° respectively. The greatest heat, 61°, occurred on the 13th in 1842; and the lowest cold, 11°, on the 13th in 1846. During the period 147 days were fine, and on 91 rain fell.

IS THIS POSSIBLE?

OUR village a few years ago was famous for the display of flowers in the windows of the poor. Such flowers have now almost disappeared. I was informed, not long since, that the reason why they are not now seen is because certain ladies of middle age, intending to be philanthropists, had discountenanced the custom! Is this a sort of increasing goodness that prepares for the poor? I trust not; for I know the ale-house frequenting does not decrease here."

That is an extract from a letter which we have received out of Oxfordshire; and did we not know the character of our correspondent, we should reply to our own query—No! it is not possible.

We have the greatest respect for, and heartily approve of, district visitors who do their ministering wisely—they are then agents of comfort and improvement; but they strangely mistake the path they ought to tread, and become workers of evil to the poor man, if they teach him and his helpmate that to practise gardening and to adorn their home with flowers is not conducive rather than opposed to the performance of higher duties.

There have been, and there are, some minds which consider austerities and self-denials of the most innocent gratifications are modes of worship pleasing to God. Thus, we heard a lady, not now upon our list of friends, once say, "I never partake of anything I am fond of."

Now, so far from considering such sentiments pleasing to our Creator, we are well assured that they are a wicked misapprehending of His attributes and of the purposes for which He created man. His Maker intended him to be happy in this world—every contrivance throughout creation has for its object something beneficial. Whatever of pain and sorrow nar the enjoyment of life are the results of man's own evil doings—his abuse of the things of the world, not his legitimate use of them.

Among these abuses none is so all-prevalent as drunkenness. It is the curse of the poorer classes of the British Islands; and few are their felons who would not subscribe to the dying murderer's confession—"Had I kept from the drink I had not died this death."

To keep a man from the beer-house, the first step is to make his home comfortable and smiling; and it gladdens us to be able to say, that every year in all our Islands we see an increase of those "fragments of Paradise, though dimmed." In such, and we speak with authority, dwell the most sober, industrious, able, and godly labourers of our land.

We know many, very many, such cottages; scrupulously clean within, with a tidily kept, well-stocked garden around, and a row of Geraniums and Fuchsias on their window-sills. They are cottages of which the man is proud—deservedly proud. He does not feel degraded

by being the tenant; he feels that he is a happier man by being there rather than in the tap-room; and that feeling of happiness is the stepping-stone to the higher sentiment of gratitude.

It is of no avail to say, as we have heard said, "He ought to feel that gratitude without those adjuncts. He ought to read tracts and his Bible in the hours he devotes to his gardening." It is of no avail to say this, not merely because man will not give up all his leisure to those books, but because it would be contrary to his duty to do so.

It is a man's duty to employ some part of his leisure so that he may add to the comforts of his family, and yet so recreate himself that he may be more fitted for his daily labour. Now, gardening effects both these purposes—to the labourer it is an amusement, and it adds to the provisions for feeding his family.

A wise endowment of man's nature is a tendency to congruity. He is dissatisfied with violent contrasts. Thus, the tidy garden is always associated with a tidy house and tidy clothing. We never knew an instance to the contrary. Cleanliness, says the proverb, is akin to godliness; and the district visitors' ministering is more effective, is an easier task, with the cleanly garden-loving cottager than with the tenant of a dirty cottage and the husband of a slatternly wife.

When we took up our pen we had no intention of writing such a long homily; but we have the subject upon our heart, and then out of its abundance thoughts will flow copiously. It rejoices us to know that the experience of a vast majority of the parochial clergy coincides with our own—gardening makes a man a lover of home, and a lover of home is rarely an ungodly man.

Even whilst we are writing these words we have received this testimony—"Our parish is not what it used to be. The horticultural show and the clothing club have wrought a vast alteration in the appearance of our people and their dwellings. Their habits, too, are changed. There is no Sunday-ericketing, and in five years the number of communicants has doubled."

PRESERVING ICE.

I HAVE seen the description of an ice-house of Mr. Blundell's. It is one of the very best-constructed of all those old-fashioned ice-houses for keeping ice on the "preconceived-notion" of the last two or three generations; but if all the scientific men of Europe, since Humboldt was thirty years of age, had put their heads together to devise a plan for wasting ice, they could not, possibly, have hit upon a better plan for doing it than these preconceived-notion ice-houses, and there is not one of them in the three kingdoms that I would take as a gift, if I were going to keep ice for myself.

My early pursuits led me into the laboratory of Nature, where ice is kept to perfection, and I can give the natural history of keeping ice, and of wasting it, both at sea and on land in all parts of the world. I made the subject a hobby during the last forty years, but my notions were ripe on it before the beginning of that period.

When I saw the first ice-house and began, in the civilised world, to talk about keeping ice, all my "preconceived notions" on the subject were turned upside down, and I was amazed to learn that all around me were perfectly daft on what seemed to me so plain a subject. I told the tale of the secret of keeping ice on a plan that was based on the law of Nature, as is well known to the early readers of this Journal. The Americans took advantage of that plan, and they succeeded with it to perfection; or if they did not, Dr. Lindley is in for it, for he even told his readers, not long since, the invention was all their own.

Now, I write this for the purpose of breaking up preconceived notions about ice and icing, just as I would break up iced things themselves in the still-room after breakfast, in order to begin a new start. And we start at once to the Gulf of Mexico, take it for granted there is a burning sun and a stiff land breeze there, and a huge iceberg still as big as when it rounded Cape Breton. Now, what are your own notions about the effects of the sun and breeze on a huge iceberg—say as big as the Crystal Palace, in those waters, supposing the thing to be possible as I put it? Shall I guess? Would it not be melting down and dripping like a tub of butter before the kitchen fire? Of course it would, if we had no better experience than preconceived notions that it could not be any such thing, or anything like it. Now, I never saw an iceberg nor the gulf; but I have no hesitation in saying that no one ever saw an iceberg dripping anywhere, with a strong sun and a strong wind playing against it at the same time. Such a thing could not happen under the present condition of things, even supposing the rays of the sun to give 100° of heat, and the air 80° to 90° at the same time. The effect must necessarily be, on such a huge mass of ice as I have supposed, to have the whole of its surface quite as dry as the surface of the glass on the Crystal Palace in the hottest day in summer, save and except a certain space all round the lower portion of the sides next above the water line.

Here, then, is plenty of elbow room for the incredulous and for preconceived notions. If the heat of a tropical sun, assisted by a strong land breeze at 80°, cannot melt ice when packed in vast quantities, how can you prove that a current of air at 65°, without the help of the sun at all, has any power to melt ice on a small scale in the common ice-house? I say it never could have had such power under the circumstances in any portion of the globe, whether you can believe or not.

To ventilate an ice-house when the air is at the freezing-point, as Mr. Blundell suggests, is of little or no use whatever in saving the ice, for then the air round the ice not to be in motion would be better, it would much sooner get intensely cold. You never want a current of air till the ice begins to melt: the current will not keep the ice from melting in July, and there is nothing under the sun that will. But a current of air will keep the melting at a minimum of waste; and a column, or volume rather, of confined air round a heap of ice, is much more wasteful to it than if the sun was let in upon it at a temperature of 96°. More room for doubts, fears, and scepticism.

I know from my own experience in this matter how difficult it is to get rid of preconceived notions. Thousands will not believe one word of the natural history of the iceberg—it goes against the grain altogether. But I shall give the question another turn where we can have witnesses by the thousand to prove the correctness of my statement. Every reader may have his witnesses, and I shall call none, but shall bide by what they say.

We take a tour of the Alps at the end of August, keep to the Italian side of the mountains full facing the sun, keep to the middle height of the mountains at the same time for safety—that is, to be safe from an opposition law which is in force higher up the ascent. The law of perennial congelation affects the opposite law much lower down than the "snow line." Well, we come upon a huge mass of snow which was drifted into a great hollow. The sun is 96°, and the air in a strong breeze not quite so warm, if we could make out the difference between the two. Here, then, are exactly the same conditions under which we left the iceberg in the Gulf of Mexico, barring the one I mentioned next to the water line. If the iceberg was melting like butter, how much water could one gather in such a day from the face or surface of one acre of that huge mass of snow? Call travellers—but they, too, tell incredible things. Then call the Swiss mountaineers—there are plenty of them in London, and they ought to be the best ice-keepers of any. Now, there is not a man in Switzerland, or out of it, who ever saw the surface

of a vast mass of snow on the south side of the Alps, or in any other part on the face of this earth, with the surface of it even damp on such a day. We said one acre was the extent of the surface of our experimental patch of snow, and I maintain you could not possibly damp a cambric pocket handkerchief all over that surface, and I was never there nor out of this island. Then, if the current of air at 86°, assisted by a strong Italian sunny day is not able even to damp the surface of icee snow, how can a current of air at a temperature of 65° melt ice itself, and no assistance from the sun, down in the ice-house? Dry air in rapid motion never melted ice since the flood, and from that period dry air in rapid motion has been the best agent yet discovered for preserving ice: and I assert without the smallest hesitation, that air which is not dry and which is not in motion, is the best agent in Nature for wasting ice.

I could give the proof in the laboratory of Nature herself, where I took up my notions from seeing the process in actual operation; but I shall refrain unless I am pushed into an ice corner.

I shall give a more practical turn to the subject now; and suppose that I did accept of one of the present and old-fashioned ice-houses as a gift, and set about arranging it as I would have it to be useful to me, the first thing I would alter would be the waste-drain at the bottom. There is a syphon or air-trap to exclude the air at the mouth of the waste-drain. That air-trap I would pull up, then the whole of the drain, and I would make an air-drain of it about 10 inches wide and 10 inches deep, with a waste-water-pipe drain down the centre of it to the open air, where I would place a trap-door to shut out or let in a current of air as I seemed to want it, and as the outer air seemed to me to be in a fit state for drying the sides of my ice all round the heap.

The present mode of excluding the air from the bottom of the ice-house I take to be the most unscientific construction in all our domestic arrangements. Ninety-nine pounds out of every hundred pounds of ice that are wasted go through the waste-drain for want of bottom ventilation, and from no other cause whatever. Of course, I would have no brushwood, or straw, fern, or stubble at the bottom to place the ice on—nothing but a strong lattice of oak or red deal, and on that I would prop planks on end to stand upright against the walls of the well and to stand 1 inch apart, the one from the other, and I would continue the planking that way as high as the ice, and leave a free passage out at the centre of the dome.

This, you see, would be having a nonconductor and a volume of air (behind the planks) all round and at the bottom of my ice; but my ice would melt for all that, and all ice will, more or less; but my ice would thus be constantly at the very lowest degree of the melting scale in such places, and I am not aware that there is any other substance by which I could reduce the melting so much.

I am quite certain I could make an ice-house that would hold the ice better than by this plan. But there is only one way, and this is the principle of it, of getting the maximum of ice out of any one of those which are made on preconceived notions, for the notion was entire and altogether highly unscientific and quite contrary to the law in Nature which rules the subject.

D. BEATON.

FUMIGATION WITH TOBACCO PAPER.

RECENTLY we had business communications with Messrs. Griffith & Avis, Tobaccoists, of Coventry, about the purchase of some of their tobacco paper. In one of the letters of the firm to us they say, "Never use anything to light our paper but ordinary brown paper; some use cinders, forgetting they throw off sulphur." Using cinders had been our mode of procedure, except occasionally in the case of fumigating tender-foiled plants, we used pieces of brick made red-hot at the furnace fire. We determined on trying this plan, and did so a day or two ago, and as the minutiae may be of use to others, here they are.

We generally use a No. 12-pot, a cracked or damaged one, of which there are unfortunately too many about, collected some refuse paper, papers that bulbs had been wrapped in, lighted the bottom piece, then half filled the pot, pressing down a little, so as it might burn but not blaze, then put on the tobacco paper, quantity according to the size of the house (of which no one can judge till they have fumigated once or twice, as some houses are

glazed with wider laps than others). In our pots we have a round hole at the side just level with the pot's bottom inside, and in this we insert the nozzle of a pair of bellows, if the paper from being very damp does not burn freely.

The house will soon be full of smoke, and with the paper wasting slowly the house is kept full a long time. We generally fumigate in the evening—say 4 or 5 P.M., at this time of the year, and leave paper burning till morning.—N. H. P.

GRAPE VINE PRUNING.

Of all the fruits we cultivate, the Vine claims precedence, whether we consider the wholesome quality of its produce, or its importance in wine making; the interest which has ever been attached to it from the remotest ages of the world, or the gratification it affords to every man "to sit under the shade of his Vine or his Fig tree." If proof of the mutability of our English climate were wanting, the existence of vineyards in many parts of the country formerly, would go to prove it; for in these very localities, in the present day, Grapes do not ripen in one season out of three with certainty. In the old town of Abingdon (near this place), formerly written Abbey Town, there existed a large abbey, and as the ecclesiastics of old did not neglect to provide things temporal as well as spiritual, there was attached to it a vineyard. But such an experiment would not succeed now. The culture of the Vine in the open air cannot now (unless in our southern counties), be depended upon, and those who do not wish for sour Grapes, had better not attempt it. The remarks which follow upon pruning will apply with equal bearing upon in-door and external cultivation.

Vines are generally raised from small cuttings with one bud and a little piece of last year's wood attached to it (fig. 1).

Fig. 1.

Sometimes they are raised from layers, but this is an obsolete mode. The cutting being placed in a small pot in a genial heat, soon emits roots, and after receiving the necessary shifting and attention during one season, becomes a young Vine (fig. 2).

Our young plant has now arrived at the state in which it would be offered for sale in the nurseries, and we will suppose that the requisite number and proper selection of Vines for either a house or a wall has been made. Whatever the season of planting may be, the young Vine must be cut back to two or three of its lowest buds, for the purpose of concentrating its energies, and in order that the sap which would have nourished an indefinite number of weak shoots, may produce only one vigorous growth. If all other circumstances are favourable, the Vine will reach the top of the house the same year. It is then time to decide whether a separate Vine shall be trained to every rafter, or whether one Vine shall fill a portion or the whole of any allotted space. If it is wished to have several bearing stems to a single plant, the Vine must be again cut down to two eyes, about 18 inches in height, and the shoots which grow trained horizontally right and left; these are intended to form the main branches from which other shoots will be trained perpendicularly, as in fig. 3. The distance at which the perpendicular shoots may be, must be regulated by thinning the buds on the shoot *a* at discretion. We will now suppose that each bud has made a vigorous shoot in the third year from planting, the Vine will have its full figure, and fruit will be expected.

The fruit of the Vine being produced from the second season, it becomes necessary now to decide in what way that wood is to be produced so as to furnish an annual supply of fruit-bearing shoots. If all the eyes produced on the growing shoots were allowed to break, there would be a crowding and confusion of foliage, and too many bunches of Grapes would be produced. Now, as it is better to prevent a waste of the sap, than to remove either too many leaves or bunches after their production, the eyes must be thinned, if short-jointed wood, taking out two and leaving two (fig. 4). This will leave the buds which are to form the future spurs upon alternate sides of the main stem (fig. 5). When the Vine again makes shoots,

Fig. 2.

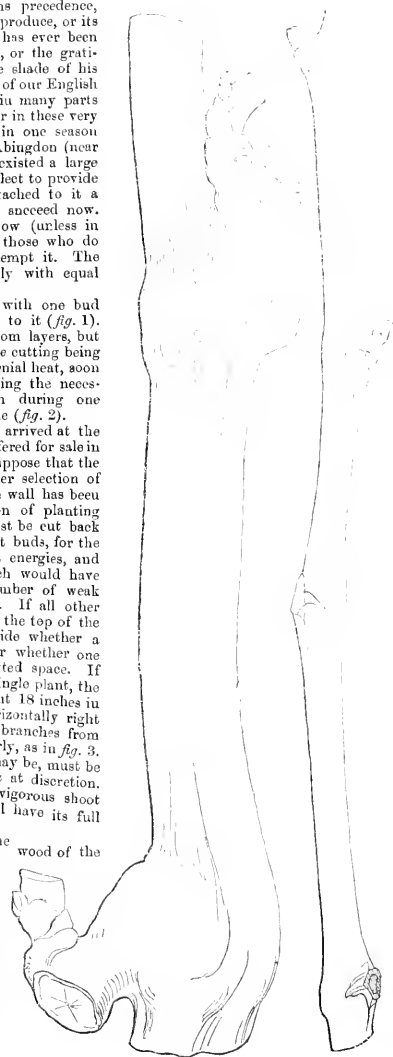

Fig. 3.

Fig. 4.

wood of the

one or more bunches of Grapes will appear at the third or fourth joint of young growth, which must be reduced to one only, and the young shoot beyond it stopped with the finger and thumb—thereby only allowing as much foliage as can be fully exposed to the light; this stopping will cause other shoots to push from the axils of the leaves of the first shoot, which must not be removed, but stopped again at one joint from their origin; were they taken away entirely, it would have the effect of bursting the buds on the shoots which are to form the next year's spur.

Fig. 3.

We will now suppose that a young shoot of the previous year has produced fruit for the first time during the past year, the shoots on which the fruit was borne diverging at nearly right angles from the stem. They will now form what are technically called spurs, and are to be shortened back to within one or two eyes of their base. In addition to the buds formed on the young wood, adventitious ones sometimes push from the base of the old spurs; these, if well placed, must be carefully retained in order to keep the spurs "at home," and prevent them becoming unsightly objects. Such is the mode in which what is called the spurting system is managed, although some cultivators prune the spurs off close to the stems of the Vine, and the crop is produced from buds which push out from the naked stems. This can only be applied to Vines of great vigour.

The fruit of the Vine being produced by the wood of the previous year, there is another mode of procuring it, which is much practised also. It is called the long-rod system, and consists in having an annual supply of young canes from bottom to top of the house or wall. These have their buds thinned as has already been described, but after producing fruit they are cut away, to be replaced by other shoots from the base. This system is more favourable to the production of fine Grapes with the Muscat kinds, and the Dutch Hamburg succeeds better so than by spurting. If large bunches are desired this is the way to get them; but for Grapes for market there is no better system than by spurting, the object being to obtain medium-sized, compact bunches, with perfect berries, of large size and good colour.

There is a pruning of another kind—the thinning the berries. The skilful performance of this is of much importance, and the sooner it is done after the formation of them the better. The operator should be provided with a pair of fine-pointed sharp scissors, and should wear a thin, clean, and soft glove, to prevent the perspiration of his hands coming in contact with the tender skin; his head should also be covered with a silk handkerchief, to prevent injury from contact with the hair. Too much care cannot be taken in the performance of this work. The thinning must be accomplished gradually—say at two or three times, taking care always to leave the most prominent berries, and to give greater space to the larger growing kinds. Frontenays and Muscadines, with Black Prince Grapes, are not improved beyond a certain medium of thinning the berries, and care must be exercised not to destroy the compactness of the bunch by immoderate use of the scissors.

Early pruning is most desirable, nay, essential, for the Vine; it should be done as soon as the leaves fall, for this reason, that the roots are slowly accumulating sap during the period of repose, the whole of which is intended to support the buds in their young state; and, of course, the fewer they are in number the more vigour they must possess. The Vine, too, of all trees is least calcidit to endure the evils of late pruning, and when this occurs it always bleeds, by which is meant that the sap exudes in copious quantities from the orifices of its channels, which have not the power of collapsing. The effects of losing a large quantity of this fluid just at the time it is most required, is to induce debility, and in extreme cases death. Various nostrums have been recommended as means for bleeding, but it is best to prevent its occurrence. We say, therefore, prune early; or, as this term may apply differently to early-blossered or late Vines, prune as soon as they are at rest.—H. BAILLY, *Gardener, Nischan Park.*

VISITS TO SOME OF THE FRENCH NURSERIES.—No. 4.

THE ENVIRONS OF PARIS.

THE difference between the English and French taste for flowers and plants strikes one sufficiently at all times, but especially so when visiting the smaller nurseries around the metropolis. In the environs of London we find nurseries, both large and small, who grow every variety of plants—some for the supply of Covent Garden Market; some for the gratification of individual taste, such as the Orchid and stove plants for the wealthier class, and the florists' flowers for those who have less means at their disposal; and others myriads of bedding-out plants for the vast number of persons who in their little villa gardens delight in having their beds of Verbenas, and Scarlet Geraniums. One is struck in Paris at the total absence of all this. Two objects

seem mainly kept in view—the decoration of the in-door apartment, or some large and showy plants for the shrubbery or public garden. It would be vain to look near Paris for such an establishment as Mr. Turner's, of Slough, or Mr. Henderson's, of St. John's Wood; and even where we find the cultivation of anything like a florists' flower, such as the Phlox or the Rose, it is the foreign trade which is most thought of. This arises, as I have before said, from the want of real love for flowers. A French gentleman or lady admires, but does not love them; they think them pretty, they help to set off their room when they give a ball, and hence Dracænas, Cordylines, Chameælis, Phorinus, and such-like plants have great charms for them, and are in great demand; but to spend the time, money, and trouble on them, that are so cheerfully accorded around our great city, is quite foreign to their notions. Greenhouses, instead of being the rule as with us, in most good-sized houses, are there the exception. This was the common subject of complaint amongst the French nurserymen, and I could see had some ground in it.

MONSIEUR LIEVAL,

of Ternes, between the Bois de Boulogne and the Parc de Montceaux, is well known to many admirers of the *Phlox*, as the most successful raiser of seedlings in France, or, indeed, elsewhere. Lieval, Madame de Wendel, Dr. Lacroix, and a host of other varieties, sufficiently testifying to the skill with which he has worked, and to the success attending his perseverance. The autumn having been a most beautiful one, they had continued in bloom up to the period of our visit; and although, doubtless, individual varieties were not as fine as earlier in the season, yet one could form a tolerably good estimate of them. Now, the *Phlox* is admirably suited to the dry, clear atmosphere of Paris. It is not liable to be shattered by rains as with us, even in the south of England, and I, therefore, saw it under as favourable circumstances as could well be. Is it, then, likely to be that universal favourite we were some time back told it would? Is it to supersede the *Pæonia*, and to be regarded as far surpassing that grand autumnal flower? My own opinion was decidedly expressed some time ago, and I can only say that it was fully confirmed by what I saw at Monsieur Lieval's. He not only grows a large number of seedlings himself, but Mons. Fontaine, and others, grow upwards of 10,000 for him. From these the best are selected for his own ground, and for the purposes of propagation; and I could not but be struck with the great sameness of colour and marking—white with a dark eye, and crimson or rose with a deeper eye of the same, constituting, apparently, the types of all.

Before they can ever, then, be universal favourites, some variety of colour must be introduced into them. Whether this is possible must be a matter for the consideration of raisers; but we do now want some variety, and even were this overcome, the injury that they so readily receive from rain and winds will be against them.

Monsieur Lieval, out of the large number of seedlings, has selected six to be sent out this autumn. Some of these I saw, and certainly, as far as shape and size are concerned, they are an advance upon their predecessors. In sheltered situations, and in mixed borders, nothing looks prettier than a good *Phlox*, and anything I have said in disparagement of it is only intended to counteract too high-flown expectations as to its capability of becoming a first-rate florists' flower.

To Monsieur Lierval the French are indebted for the numerous varieties of *Canna*, which now form so prominent a feature in the public gardens of Paris, and France generally; large clumps of them being found in the Champs Elyées, the Tuilleries, around the Tour de St. Jacques, and other places. Some years ago he set himself to the task, and now he has quite a *specialité* for their cultivation. They certainly are very fine, and give quite an exotic character to the garden, and take away that extreme flatness which is the eyesore in the bedding-out system as practised amongst us.

How it rejoiced my heart to read in THE JOURNAL OF HORTICULTURE last week, from so able a judge as Mr. Fish, these words—"The mind longs for change. It pants after a massive background to throw back the dazzling colours; and amid the bewilderment of such splendour, it sighs for the relief of light and shade instead of level massive gorgeousness." Just so; and as it is in dress so in this. Betsy must wear a crinoline as well as her mistress, and James thinks it a hard thing if he cannot wear laydowns and mauve ties as well as his master. So every little gardener (like your humble servant), must bend too, for to be out of the fashion is to be out of the world; and if my lord close by has his geometrical, of course we must try it.

Now, if these Cannas would but do here, they would be grand things to come in for this purpose. And doubtless when the new variegated plants from Japan, which Mr. Standish is now introducing to the world, become more common and larger they will add a new feature to the English garden.

Monsieur Lierval was busily engaged preparing to cut down his Cannas when I was there. They are cut pretty close, and then stored away in dry cellars on sand, so as to keep them clear of frost and damp, and planted out in the following spring, the roots easily dividing; the habit of the plant being to throw up suckers. Amongst the prettiest and most remarkable varieties I noticed *carnea*, *musifolia*, *minima*, and *Van Houttei*, the latter with yellow and scarlet flowers of considerable size. Generally speaking the bloom is not of much importance.

Another plant now used in and about Paris for ornamentation is the *Ricinus* (Castor-oil plant), which attains in a single season the height of 8 feet or 9 feet. One variety cultivated by Mons. Lierval, and called *sanguinea* from the dark red character of its stems and leaves, is very ornamental, and was then in full fruit, bearing large numbers of its curiously marked seeds. The greenhouses were filled principally with *Geraniums* and soft-wooded plants, which Mons. Lierval sends to the flower market held in the "Place de la Madeleine;" while another house was devoted to the culture of the *Cordylines* and kindred plants for the purposes I have before alluded to.

The aspect of the nursery was quite foreign to our notions, having rather too much of negligence about it. Business is attended to, and nothing can be kinder or heartier than the manner in which we were received by Mons. Lierval and his son. Indeed, the geniality seems common to the craft on that side of the water, as, indeed, it is with some few exceptions, on this side also.—D., *Deal*.

RENOVATING OLD ORCHARD TREES.

In my gardens and orchard are many large fruit trees, Pears, principally; but also Plums, Apples, and Cherries, which have had no attention given them for years—six years, at least, I can tell; consequently, the crops are inferior every way. The bark is generally very ragged or scaly, and the trees full of spray and long, thin, pendulous branches. Will you inform me what is the best mode of proceeding to restore them to the best possible condition? They are old trees—twenty or thirty years old—but are such an ornament to the grounds I cannot remove them.—B. W.

[Your case is one of a great many, and we thank you for bringing it before us; but if you had stated a few more particulars respecting the situation, character of the soil, and other matters, it would have been easier to have suggested a remedy; but, supposing the worst evil to be against you—that is, superabundance of moisture in the soil, then drain it as quickly and thoroughly as possible by all means. This done, thin out some of the small spray wood, and also some of the old branches; but do not be too severe in that way on old trees, for, like animals and the human family, severe amputation is not easily got over late in life, so that extensive fruit-growers prefer destroying an

old orchard to over-pruning it when it gets old; but the trees may be made more orderly-looking by cutting out all awkward-grown branches, being careful, however, to cut as little as possible from the Cherries. Apples and Pears may be cut more freely; and if it be advisable to introduce other kinds, cutting the trees down to something like a dozen forks or heads for grafting may be advantageous, if the trees be not older than what you say; but if very old and worn out it is useless to graft; for, although the grafts may grow and even prosper for three or four years, it is usual to see such trees die off at some unexpected time. But, supposing the trees to have been slightly pruned as described above, the next thing is to whitewash the bole and part way up the large branches with a thick coating of lime whitewash; and some mild mowing in April, when there is a heavy dew, or when the trees are wet with fog or rain, let a man dust them all over with freshly-slacked quicklime. Much of this will, of course, fall to the ground; but a part will stick to the moss-grown branches, and lime being at variance with moss, will kill much of it: of course some of it may be removed at pruning time; but it is not easy to remove it all, and the above is the easiest way of destroying a part.

If your orchard be on ground kept in tillage, much good will be done by only digging slightly between and amongst the trees, as deep digging and heavy cropping are injurious to the welfare of the trees. Cherries do best on grass; but it is not necessary for Apples or Pears to be so. Much, however, depends on the subsoil, and something on the situation; but all these things added together tend to make an orchard look older than it really is; for under favourable circumstances it ought only to be in its prime at twenty or thirty years old. If, however, the remedies given above be not attended with the desired result, grubbing up is the only alternative; but do not plant trees there again until it has been a year or two under cultivation of another kind, and all draining and trenching that may be required may be then effectually done.]

A FEW DAYS IN IRELAND.—No. 7.

GARDEN FARM, DRUMCONDRA.

THIS truly beautiful place, situated on the slope of a brow some three miles north of Dublin, commands one of the finest views of the metropolis, from east to west, the Dublin mountains, and the summits of the Wicklow hills, and is the property of Mr. Niven, than whom no man living could more thoroughly appreciate its charms and pleasing associations.

More than twenty-five ago we formed an acquaintance with Mr. Niven in the "Gardeners' Magazine," and having never seen him personally until we met him the previous day at Mr. Mackie's, we could hardly believe he could be *the* Mr. Niven, so young and slim and active he looked; whilst we had formed a sort of idea of a great, tall, stout man, with an expansion of body somewhat commensurate with the largely developed refined taste, the artistic and poetical eye, the elevated thought, the correct judgment, and the untiring energy to improve and make better each and every thing that came in his way, that we for long imagined to be his peculiar characteristics. And, now, after having passed through the initiatory trials and troubles of gardening, after having given the benefits of his genius to the vice-regal lodges at the Phoenix, and the beautiful botanic garden at Glasnevin, it was very pleasing to find him at an early hour in the morning, not "sitting under," but actively at work among his own vines in that little paradise which he has formed out of what previously was a tangled scene of briars and thistles, desolation and ruin; the very strength and luxuriance of the weeds, which would have appalled many, telling him that such soil rightly used, would be equally fertile in producing vegetables, fruits, flowers, and shrubs, for the use and pleasure of man.

The title "Garden Farm," appropriate as it is, will not give a right idea of the place to our readers, unless they can associate with that all the interest and neatness of a well-kept pleasure ground and flower garden. The entrance gate of elegant iron workmanship, with its suitable pillars, stands at right angles with the highway, but sufficiently back from it to permit of a nice sweep on each side bounded by a wall. A little from the gate there is a pretty lodge, so that the gate may be properly attended to. Besides the dignity which the above sweep gives to the entrance, room is provided for carriages to wait, without intruding on the highway; as, though the place might by some be considered a demesne, Mr. Niven just calls his pretty home a

cottage, and, therefore, neither carriages nor horses are allowed inside the gate. We found out this from noticing how nice the road or broad walk was kept. The Lord Lieutenant and the Lord Mayor must here be on a par with the visiting gardener. Having only an umbrella for a pony, we could take it with us. There is a back way for carts taking manure, of which vast quantities are used, and bringing and removing other things; but Mr. Niven escapes all the anxieties of horses and stabling, by hiring at so much per ton when wanted, and finds that it is for him by far the most economical.

The breadth of this fine walk contracts a little after you pass the first curve from the gate, and then about a hundred yards more or so, it is joined by another at right angles some 6 feet wide, that takes you up the slope of the hill for some two hundred yards to Mr. Niven's cottage. The sides of the first walk, in addition to commoner things, are well stored with all the newer shrubs and trees in excellent condition, and so as here to conceal all traces of the market garden. Beyond the point of junction referred to, the walk is carried on, but gradually assumes the character of the useful among acres of fruit trees, and Rhubarb and Sea-kale. The narrower walk leading to the cottage has a new house on each side, about 40 feet from the walk, of which Mr. Niven has kindly sent us a section. From these houses to the walk the space is filled with flower-beds. Nearer the cottage or mansion the ground is chiefly occupied by the finer shrubs and smaller evergreens, but grouped instead of being arranged in lines or square beds. The house has a terrace landing of its own, a sloping bank, and steps in the centre, and some fine shrubs on the slope, and all the openings carpeted with *Cerastium arvense*.

We forgot to mention that there is a wide margin of the same by the sides of the walk from the gate, which, without examining, we took to be the Moss Saxifrage: it is close, compact, and green—a sheet of white in early summer. It gets a skiff with a scythe once a-year, and the sweepings are used for covering fruit trees in pots to lessen evaporation in summer; for here every—even the smallest—thing is made to serve a purpose. Beyond that sloping bank there is a regular flower garden of shrubs, chiefly the best and most valuable evergreens, *Cupressus*, *Tujas*, *Wellingtonias*, *Araucarias*, &c. The beds are laid out quite artistic, some of them have only from three to five plants; but all the beds divided from each other by some two-foot gravel walks, and each bed is surrounded with its own low hardy edging, as *Crassulus* of sorts, *Sedums* of sorts, *Silenes*, *Gentiana acualis*, *Thrift*, especially a very dark variety, *Cerastium tomentosum*, *Sempervivum*, and *Saxifragas*, &c. Here is a fine reserve for alpine plants. Of course the fine little trees in all these artistic beds are for sale, as well as those elsewhere; but it requires little more trouble to take them up and replace them than if the same work was done in nursery lines; whilst in such a position the so managing them gives an artistic ornamental character to the place that any common arrangement would fail to effect.

Having mentioned the edgings of these beds, we must not omit to state that a little farther westward a long-raised bed, some 5 feet wide, is devoted to a rich collection of alpiners; boards and stakes keep up the sides of the bed, some 18 inches above the ground level, and thus the plants are kept from many enemies, and much easier examined by the lovers of the minute in vegetable beauty. In passing we may notice, that the *Cerastium arvense*, of which there are such quantities here, seems a darker-foliated variety than what we used to consider as the arvense, which had a little of the grey in its small foliage, and this led us to think at first that it was a variety of the Moss Saxifrage. For shady places, and even in sunny places, where it can get something cool to cling to, as little stones, &c., the *Saxifraga hypnoides* makes a fine verge, where there is little necessity for trampling or sweeping; and this *Cerastium* of Mr. Niven would be even easier managed, and would yield the attractions of a green bank or verge, at a tithe of the ultimate expense of a grass one well kept. Some amateurs stare when I tell them that their grass verges will be more expensive than their flower-beds; but they begin to find out what it is to keep them nice, by machinery, or mowing, and clipping, and picking, and sweeping the edges once a-week, or ten days at farthest, all the summer time. Contrast this with the switch of a scythe once a-year.

In the alpine-bed, among others too numerous to mention, were some fine little *Gnaphaliums*, and especially *doicum*; *Erinus alpina*; *Sempervivum californicum*, a beautiful gem for setting round some little flower-bed where the flowers were only a few inches in height, and others of the same genus, as *ciliatum*,

crustatum and others; *Hieracium glabra*, a green trailing plant much smaller than the *Cerastium* spoken of above; the beautiful dwarf-trailing *Thymus azoricus*; *Silene exscapa*, for clinging to a stone or rock; *Saxifraga* in great force, some of the rarest being, perhaps, *Rachelie*; *Caryophalea*, a very dwarf sort with large white flowers; and such kinds as *oppositifolia*, and *oppositifolia alba*; *Draba aizoides*, *Aizoon*, *pilosa*, &c.; *Arenarias*, as *balerica*, so close in habit, and *laricifolia*, so close, and green, and creeping when the white flowers are gone; *Phlox subulata*, and all or most of the best dwarfs as *procumbens*, *verna*, *stætea*, &c.; *Frankenia levis*, a pretty low green trailing plant; and so are *corymbosa*, *mollis*, and *ericifolia*, which latter is a little tender, as it comes from the Canaries; *Veronica saxatilis*, a pretty minute beauty; and numbers more equally small, as *serpyllifolia*, &c., and the pretty-leaved trailing *Polygonum complexum*, &c.

North from these alpine-beds are large quarters of fruit trees trained to trellises, and of all sizes, so that a gentleman might come with his gardener and pretty well stock his walls and quarters at once. These trellises are formed by driving in stakes along the centre of a ridge, and then fastening slight rods lengthwise on each side of the stakes. These ridges are considerably elevated, and in some cases are 9 feet apart, and in other cases 11 feet or more; but when that width and wider, there is generally a row of dwarf bushes or pyramids in the valley between the ridges. Though the trees be planted on each side of the trellis, yet from being so elevated, and large and small so regularly moved, they can be raised easily with a fine supply of roots, and if planted early would bear the following season. Apples, Pears, Cherries, Plums, &c., were in excellent condition. In other quarters trees were trained as bushes and pyramids, and pinched in so as to be masses of flower-buds. Other places had lots of trees in the bush and pyramidal style, seemingly more for fruit than for sale; and in these the ridges were covered as undergrowth with Strawberries, and apparently in the highest luxuriance. Besides these banks acres of ground are devoted to Strawberry culture—some planted on the level, some on the rounded bed, and all looking well. Many sorts are grown, but Mr. Niven thinks none for quality and quantity comes near to the Princess Frederick William—one, we think, of his own raising, and which must be prolific indeed, as on comparing it fairly with every other fashionable and well-proved kind, he found that it yielded at least a third more produce.

Other small fruits are cultivated to a great extent, and chiefly for the fruit being sent to market. There were great quarters of Raspberries that you could scarcely see into, they were so luxuriant, and several plantations of the last and the present year. These two are raised on banks at first, to give more room for green and other crops between them for a year or two, and by that time the dunging and enriching the ground brings it pretty well to a level, and the roots of the Raspberries monopolise all the advantages. Rows and quarters of Currants and Gooseberries are nicely pyramided and summer-pinched, to concentrate the fruit-buds, and thus not only enable the fruit to be easier gathered, but secure the greatest amount of fruit in the least possible room. Plenty of these and most fruiting trees may be raised at once for orchard-houses or miniature fruit gardens. For those who prefer plants in pots, we observed many nice little plants of Plums, Cherries, Apricots, &c., plunged in pots out of doors; but most of the young bush and pyramidal Peach trees, and the tenderest Apricots, &c., were still in the orchard-house, and in such a wet season be likely to continue there until the leaves were dropping at least.

This orchard, or, rather, heated house—as it is heated very successfully by earthenware pipes with cemented joints—is 75 feet long and 24 feet wide, with a raised bed on each side, and a wide raised bed in the centre, with a pathway on each side. In the side beds Vines are planted, the roots also feeding outside; the surface of the bed was also filled. The wide centre bed was crammed with nice young Peach trees, all summer-nipped, some in pots, and some out of pots, as the moving them was found to be no trouble. Looking at them, you could not tell which were in pots or which out, partly owing to the equality of growth and partly to the whole surface of the bed being carpeted with the mowings of *Cerastium arvense*. The little fire heat was found of use for them in such a wet dull season as it has been in many parts of Ireland. Mr. Niven told us there was a growing demand for such plants, and that if they did not all sell, the fruit would. The house looked rather tempting before breakfast on the 14th of September. The Vines were

confined chiefly to the width of the side bed and the width of the passages overhead; but a rod was allowed to cross the house every 12 feet or 15 feet, which gave it an elegant appearance. Over that space the bunches were pretty well as thick as they would grow; the bunches rather small, it is true, and

the berries not extraordinary for size; but Mr. Niven told us he found comparatively few would give the price for extra fine fruit; and that he could make much more money out of the heavy crop of smaller bunches. When a better taste prevailed he could meet it by taking half his present crop.

Sectional Lines of Mr. Niven's new Form of Span-roofed House.

The other glass chiefly worthy of notice are the two houses standing north and south near the walk previously alluded to. They are exceedingly well finished, very elegant, and we would rather not state the economical sum they cost. It was Mr. Niven's design to send a paper on these to some learned Society, such as the British Association, and, therefore, our readers must feel all the more obliged to him for consenting to make them the first judges of this new mode of glass-roofing. He states, "In reply to your note, I send you annexed the exact sectional lines of my new form of houses, the angled form admitting in the course of the day the rays of light and heat to act more or less rectangularly upon their respective side and roof surface. The rest I may leave to you, who have seen them in operation. Only this I may add, that my principal object in the contriving of these structures has been economy of space and capital, and instead of expensive, one-sided glass-covered walls, to have them extended, fruit or plant-house promenades, with every superficial foot of internal surface usefully occupied or available, and so finished as to be equally adapted either to the pleasure ground or the general garden."

Mr. Niven's drawing speaks for itself. There can be no question of the direct light thrown into such houses. A few things may be stated as explanatory. There was no heating of the houses when we were there. One house was devoted chiefly to Peaches, and the other chiefly to Vines. It was thought that the Vines at least would be none the worse of a little fire heat, and if both were heated a little, they would furnish storehouses for many things in winter. The houses being built on the slope of the ground, will be heated more easily than if on the dead level. A furnace, an Arnot's stove, &c., placed at the lower end, would render such a house safe, as the cold air would be drawn along the pathway to the store,

and the heated air pass along the roof to the other end. We presume the pipes on the lower lesser bed next the pathway are for heating-pipes, and instead of being covered with plunging material as shown, could be exposed when most heat was wanted. Mr. Niven was doing more in these houses than he has even represented in the drawing. The plants at the side of the path were dwarfer, but in one house the side lines of the higher bed were filled with bush pyramidal Vines, looking the very picture of health and compactness, and by stopping, though the bunches of laterals had green leaves enough, the two or three backmost buds on the shoots of the season were plump and brown. In addition to these, however, there was another Vine trained espalier fashion near the outside, which was also looking well. A similar plan was followed in the Peach-house. The bush or pyramidal trees were planted out on the high bed next the path, and another line to be trained trellis fashion near the outside, but the shoots far apart, and these to be furnished with spurs, and kept to spurs instead of young shoots by constant nipping back in summer. So that, in fact, by not allowing these side trees to rise too high, Mr. Niven was actually doing much more in these houses than he has represented in the drawing. Of course, he knows all about root-pruning or re-planting, when a tree threatens to want too much room from over-luxuriance. We have no doubt these houses will produce a great quantity of fruit, and will be a fine promenade, especially as the fruit gets ripe.

Two or three more things should be noticed. The whole roof is fixed with the exception of two or three moveable squares in the middle of the 120-foot length. Of course, the angular space above the doors in each end, and even the doors themselves, are open in very hot days. The massive brick pillars at the ends exist, as far as we recollect, only there; but lesser ones of 9 inches, we think, are placed every 10 feet or 12 feet, and on

these the plate is fixed, thus leaving the outside border and inside with free access to each other. The mode of giving air at the sides is also peculiar. The sides consist of two boards, an inner and an outer board. The inner one is fixed, but with oval holes cut in it—say 2 feet by 7 inches, and an equal space left between each opening. Thus—

The outer board is made to slide in a groove top and bottom, and openings of a similar size made in it, but the openings in the outer board will go against the close part in the inner board. When, therefore, you pull the outer board along the grooves, you may give an inch of air at each of these openings, or pull far enough to open the whole space, by having the openings of both boards flush with each other. By this mode an extra board is wanted on each side, but the expense and the bother of hinges, and catches, and handles are avoided.

Before leaving speaking of fruit, we must notice a Pear tree on the east and south side of the cottage, having forty branches and as many different kinds of Pears ripening in succession, and in common years furnishing a good supply for a moderate family. This year the supply was below the average, though there were some fine fruit. An essay on such Pear-growing was read by Mr. Niven before the British Association in 1858.

We have mentioned no ornamental trees; but we thought the Weeping Willows more handsome than usual. And speaking of the Willow leads us to say that Mr. Niven has large quarters of all the best Willows as stools, and especially the packthread Willow, the best of all for economical purposes; and all, and especially the latter, in the greatest luxuriance. Strange that so much should be paid to foreigners for Willows when they could be such a remunerative crop at home.

We find, however, that we have gossiped so long, that we must leave perhaps the best of the tale untold—about vegetables, worth the attention of young gardeners going some distance to see. We saw little of summer vegetables but Carrots, Parsnips, Turnips, and especially Asparagus, Sea-kale, and Rhubarb—acres and acres of the latter were fine. The great secret of all is deep digging, heavy dunging, and abundance of rich water. A large clothes-washing establishment stands even a little higher than the farm, connected with a female religious order; and the rich liquid from such a large place, instead of being a nuisance as formerly, is run into tanks on the farm, and, by means of moveable pumps and moveable water-troughs, is made to water and irrigate those crops that can take in all such strong food, and even look out for more. Whole quarters of Rhubarb had the rows enclosed with boards at the sides, and two or three-foot boards put across the top, ere long with or without heating material at the sides; merely from preventing the heat of the earth from freely escaping is sufficient to bring it early to such maturity as to fit it for the market. Large quantities of Sea-kale are whipped up, tied into dish-bundles, and after being a certain time in a warm dark place, are sent to tickle the appetite of the good people in Dublin.

In leaving this interesting place, we could not help wishing that the worthy proprietor might live many, many more years, to inculcate prudence, forethought, activity, industry, and honest thrift, by the most successful of all teaching—example; to impress on still many more pupils the necessity of self-denial, self-control, self-instruction, and thorough fidelity as the first necessary steps to lasting social advancement; to show them the importance of the great Christian principles of moral obligation for regulating their conduct in life; and, in fine, by his taste for and the love of the beautiful, to be the means of diffusing a still more ripening and elevating influence over the land of his adoption.

R. FISH.

MODE OF STRIKING CUTTINGS—DIVIDING AGAPANTHUS UMBELLATUS.

In your No. 27, of the 1st ult., is a suggestion of your correspondent Mr. Beaton, of a novel mode of striking cuttings by the assistance of warm air confined between the edges of a tube set upright on the ground, and a flower-pot dropped into it just fitting at the rim; the escape of air being prevented by the use of cement, or of putty.

As there would be some uncertainty in these articles remaining firm when exposed to the sun or drying wind, I venture to

suggest that a potter might make the article complete and airtight in itself, excepting the hole at the bottom of the pot, which I presume would be required.

I have a fine *Agapanthus umbellatus* just gone out of bloom; the roots have burst the pot. I am informed by Loudon and others that the plants may be increased by dividing the roots, but the season for that operation is not mentioned; for the present I have placed the plant in a pot a trifle larger, 12 inches diameter.—Z. A.

[The double pot all in one piece, as here suggested, would answer very well; but in large establishments nothing of the kind would be so handy as common pots, and upright or bulb pots, the upright ones to be outside, and to secure the space between the edges with a bit of common clay. Then, when the pots were not in this use they would be free for common work. As yet Mr. Beaton has used only the common kinds of pots and they answer perfectly. The system is very good indeed.]

The very end of April or early in May is the best time to divide a large plant of *Agapanthus umbellatus*, the blue African Lily—a severe work it is too—all the roots must be cut through the ball to get the divisions.]

INSECTS ON FERNS—SOIL FOR PRIMULA FARINOSA.

Will you please to tell me how to destroy insects on Ferns? I found a few on mine lately, and smoked them with aphid pastils. The result was that all the young fronds were killed. The plants, however, were not otherwise hurt.

"W.," at page 148, will find nothing so good as cocca-nut refuse for *Primula farinosa*—indeed, it is as excellent for all bog plants as for Ferns and bulbs.—R. W. E.

[Perhaps you placed the pastils too close to the Ferns. Fumigating with tobacco smoke, or syringing with Gishurst Compound will kill the aphides on Ferns. Thanks for the hint about British Wild Flowers.]

PEARS OF THIS YEAR.

We never knew Pears much more deficient in quantity, and never better in quality, than they are this year. They are also remarkable for their large size.

Chaumontels from the Channel Islands, weighing from 24 to 31 ozs., are commonly to be bought at the London fruiterers; and they have been exhibited even an ounce or two over the highest of those weights. The heaviest specimen on record weighed 38 ozs. and was presented to the Queen in 1849.

Recently we tasted a seedling Pear from a wall in North Wales, the parent of which Pear was one of the old Bergamots. It weighed 24 ozs., and the raiser, a clergyman, says that he has grown them weighing 40 ozs.

At the Royal Horticultural Society's exhibition in November, Mr. Solomon exhibited some imported Pears, among which were Beurré Diels weighing 2 lbs. each, Catilles weighing 2½ lbs., and twelve Uvedale's St. Germain, weighing 39 lbs. These last-named, therefore, averaged 3¼ lbs. each, which prepares us for believing the following statements in the Californian newspapers.

The Largest Pear yet.—*The Napa Reporter* thus notices a Pear:—"California is noted for large vegetable growths. We have one now to chronicle in the shape of a Pear, which is remarkable for its size. It was raised by W. S. Jacks, of Napa City; is 18½ inches by 17½ inches in circumference; weighs 4 lbs., and is of the kind called Pound Pear. It will be sent to the Eastern States for exhibition."

The Sacramento Union says:—

"An Immense Pear.—We received yesterday a Pear of the Duchesse d'Angoulême variety, the weight of which was 3½ lbs. A citizen of Shasta, in forwarding it says, under date of Sept. 26th:—"Benjamin Swasey sends you this day, through Wells, Fargo, & Co.'s Express, a Mammoth Pear of the Duchesse d'Angoulême variety, weighing 3½ ounces. It is one only of the many fine productions of his well-known orchard, at the Lower Springs, about one mile and a half from Shasta. The tree that bore the above specimen is a dwarf, three years from the seed, and has matured in all the present season, thirty-two Pears, the twelve largest of which weighed 16 lbs. 10 ozs.; the remaining twenty weighed 27½ lbs. Swasey's orchard is happily adapted to the raising of fine fruit. It is located about two

miles from the Sacramento river, among the foot hills, and lies at an elevation of about 500 feet above the river. The soil is a red clayey loam."

"A Profitable Apple Crop.—There is an Apple orchard on Benson's ranch, in San Joaquin co., containing near 500 bearing trees six years old, and all loaded to their utmost capacity with splendid fruit. We observed trees containing the finest specimens of Rambo, Red-streak, Jonanet and Gloria Mundi fruit we ever saw in any orchard. These apples sell readily on the farm at eight cents per pound, or three dollars twenty-five cents per bushel. A number of the trees are bearing as much as six to eight bushels each, and the entire product of the orchard will be worth a small competency. When the home market is satisfied, the proprietors will take what is left to the mountain towns and to Washoe, whether there is a remunerative market. All the trees have been cultivated this year without any irrigation, in a sandy soil, the surface of which is about 10 feet above the level of the water of the river."—*Stockton Reporter.*

Large Plums.—The *Oregon Farmer* says:—"Mr. S. Luciling, of Milwaukee Nursery, laid on our table, three Plums of the Yellow Egg variety, which weighed, in the aggregate, 11 ozs. The largest of them weighed 4 ozs."

These details bring to our recollection that this is the season when certain parties prow! about the country, and victimise the too-readily credulous with all kinds of gardening prodigies, such as blue Dahlias, yellow Snowdrops, and Brodding's fruits!

The last device in this way was managed by an American. Seeing some extraordinarily large Pears, of French growth, he bought a dozen—giving about 5s. each for them. He then bought five hundred maiden Pear-trees, of some common variety, at 1s. 6d. each, proceeded to two country towns, exposed the gigantic Pears in a window fronting the high street, on the market day, stated that the trees bore Pears like those twelve he exhibited, and sold the whole of his trees for 5s. each.

NOTES ON MY HERBACEOUS GARDEN

MADE IN THE YEARS 1853-4, WITH A FEW ADDITIONS.

The sum and substance of the following remarks is just this. They are notes made of such plants as I then grew in an herbaceous garden, devoted expressly to that class of plants which I had at that time under my care.

These notes were never intended to be submitted to the public, but were jotted down, sometimes in haste, expressly for my own use and guidance; but seeing that information is needed respecting any useful kinds of herbaceous plants, I copy a few of them which I think most deserving of notice, and submit them to the Editors of *THE JOURNAL OF HORTICULTURE*; and if they only add the smallest particle of assistance in putting down the present system of bedding, I shall deem myself abundantly rewarded.

NOTES OF BED NO 1, OF MEDIUM SIZE.

Filled at the beginning of October with nice strong plants of *Delphinium formosum*. These plants were obtained from old ones which were taken up the summer previously, and parted, and planted in the reserve garden. I have invariably found these to flower much stronger than seedlings.

Round the sides of the bed were Crocuses, Tulips, &c., to add a gay appearance in early spring. Some now-a-days prefer to peg down the Delphinium, but I like to see it enjoying its own natural habit, although, by following the latter course, it requires some support when in exposed situations.

The last week in April brings with it a good show of flower from the Crocuses; the Tulips are fast pushing up their flower-heads, and the Delphiniums are making good progress, with every prospect of a fine show of flower. This I consider mainly to be attributed to the early autumn planting—a decided advantage, certainly, and when practicable should never be lost sight of in the cultivation of most kinds of herbaceous plants. At the close of May we have the Delphiniums in all their beauty, and very worthy objects of much attraction.

Six weeks later, and the beauty of the Delphiniums being well nigh gone, I begin to prepare them at once for a change of quarters—that of the reserve garden. Here they will undergo precisely the same treatment as last year; parting at the roots, shading, and frequent waterings are all they require to make them good plants for the coming autumn.

The bed now is forked over, not too deeply, as it is likely at

this season to suffer from drought; and on the first dull or cloudy day I will bring from the reserve garden sufficient plants to fill it of the *Rudbeckia pulcherrima* (I cannot vouch for the accuracy of the second name). It was a variety growing about 2 feet high. These have been standing in patches about 8 inches over, and are now just pushing their flower-stalks, and will remove without experiencing any serious check, and will from this time produce an abundant display of flower till frost makes its appearance in autumn.

The above may be considered a history of an herbaceous-bed and its occupants for a year, and will show the reader what in an ordinary system has been done. What might be accomplished if a regular system was laid down has yet to be seen, but can only be attained by a zealous advocate of the subject he is handling. Objections and stumbling-blocks there are in the way of any one who dares to bring about a rival against our present bedding system, but not one is there but what will eventually be overcome.

[We hope our nameless correspondent will continue to furnish us with more of his practical notes, but we do not comprehend why he wages a war of extermination against the bedding system. He reminds us of the crusty old gentleman who preferred a grey poney to one of any other colour, and wished especially that all blacks and chestnuts should be exterminated. Now, though our correspondent likes his hobby above all others, why cannot he let others ride theirs in peace and quietude, though of quite a different colour?—Eds. J. of H.]

HEATING A VINERY—CARE REQUIRED IN BRUSHING OVER BUDS.

I HAVE a fruit-house, span-roofed, 36 feet by 28 feet, the centre of which is a raised border 11 feet wide, 2 feet higher than the surrounding borders. The raised border is planted with four rows of Vines trained to upright rods, as in southern France, chiefly Black Hamburgs. The rest of the house contains Peaches and Apricots in pots.

Through the middle of the raised border runs a sunk but exposed flue (continued into an orchard-house 37 feet by 14 feet, span-roofed, 9 feet high, adjoining the vinery and on the same level, in all 60 feet long, two brick on edge deep, double slate covers, 7 inch inside measure. The furnace is 18 inches deep and 12 wide and high, and I find it will raise the house about 10° above the outside temperature in dull cold weather. Now, as this (Yorkshire), is a very rainy sunless climate, I doubt whether I shall be able with such heating power to ripen my Grapes in good time, as from October the sun is very low here; and therefore the earlier my Grapes are ripe the better, I presume, will be their flavour. What, then, will be the cheapest way of giving additional heat to such a house? I have thought of three plans—one, to run a single 1½-inch pipe at 1s. 6d., or three-quarter-inch at 1s. per yard, round the Vine-borders, having two or three bends across the furnace-top inside as boiler. This would cost about (for 30 yards and fixing) £2 10s. or £2. How many degrees of heat do you think it would add to the vineyard? The other two methods would be enlarging the furnace to 2 feet by 18 inches; or a brick Arnot's stove, on one side of the vinery and below the raised border, which would, of course, heat one side madly. Cost I cannot tell. When should heat begin to be used? I think as soon as the Apricots set.—IGNORAMUS.

P.S.—Will you caution beginners in painting their fruit trees with soap, sulphur, Gishurst, &c., in winter not to apply the brush against the grain, or they may injure the fine scales which shield and cover the young blossom-buds?

[Unless you have openings to let the heat out into the atmosphere of the house, we are rather surprised that your sunk flue if all covered over does raise the house 10° in cold weather, though it would do that easily and more if exposed. Perhaps, however, we read the matter wrong, as our eyes even with spectacles can scarcely decipher the very minute interlining. There was given the very information you desiderate about flues not long ago in articles on "Forcing," or we are mistaken as to our memory; which articles, we may state in answer to other inquirers, will be resumed as soon as some other matters more pressing are cleared away. We think that with the power you state there will be little difficulty in ripening the Grapes, provided you have openings enough to let out the heat. To do

anything like force such a house you would require such a flue, and even a brick deeper, to go right round the house. We have not much faith in your 1½-inch pipes, unless they were made strong so as to sustain pressure, and then they would be much more expensive. In such small pipes, too, even when coiled as you state, there is a difficulty lest they get broken in the fireplace; and when so small, too, and much fire used, they soon wear out. On the plan you propose, we would prefer having pipes at least of 2 inches, or rather of 3 inches in diameter, and have a syphon bend to place in the fireplace, so placed that one side would be at the top for the flow-pipe, and the other near the bottom to join the return-pipe to fl. Such a syphon bend, 3 inches in diameter, would cost under 5s., and similar pipes 2s. per yard. Two-inch pipes would cost 1s. 3d. per yard, and that would be better than lesser pipes. Were we in our corespondent's position, however, we would so alter our furnace, if it needed any, as to let the flue alone, and set on it a small saddle-back or elliptic boiler. One of the latter could be obtained from 24s. to 32s., the former being 18 inches by 18 inches. Or a small boiler similar to those used by Mr. Rivers, and made in that neighbourhood, could be easily set on, and one pipe to go round, would do all that would be required. Telling how many degrees that would heat a house would be

very fallacious. It would then do no more with three-inch pipes than keep out frost in such weather as we had last winter. In a barn of a house we have in our experience kept the house higher with 20° of frost out of doors, than we could do with even more fire when there was only 5° of frost, but a keen blustering wind blowing.

If we used Arnott's stoves we would have a good-sized one in the middle, all above ground, and the smoke-funnel through the roof, with a damper near home to regulate draught. This would be the cheapest of all, or a small one might be made to each end. The small boiler would be the neatest, easiest managed, and in a few years would prove also the most economical.

We have just thought that if you did not want the flue in the orchard-house in the autumn, you might put a damper in where the two houses join, and return the flue back again to the furnace, and have a chimney there. Soft burned drain-tiles—that is, not hard nor glazed, and cement joints would answer well, and they could be placed along the surface of the bed. In such a house we do not see why the flue should have been taken below the raised bed for the vines in the first case, more especially as anything like forcing seems not to have been intended.

Many trees are injured by carelessness as you suggest.]

LINTON PARK,

THE SEAT OF LADY JULIA CORNWALLIS.

(Continued from page 188.)

THE above is the basket garden, consisting of a central eight-lobed flower-bed, with eight circular beds facing the lobes in the central one. Besides these beds, two curved borders nearly surround the whole. The openings left facing two important trees, one being an *Araucaria imbricata* upwards of 28 feet high and well furnished. The central bed in this group is (like the eight circular ones), surrounded with rustic timberwork somewhat under 2 feet high; and in the recesses where the lobes meet,

pillars about 9 feet high are covered with climbing Roses, and lestooned together with chains covered in the same way. These are also all united in like manner to a central pillar taller than the other, as is shown in the engraving; the basket-beds having each a bow over them covered also with creepers, and well filled with flowers, were in reality baskets in the true sense of the word. But as it is difficult to give a just description of such things by perspective only, we annex a ground plan as well, with the plants with which it was planted.

It is proper to explain that these basket-beds are surrounded by white-shell gravel, the rustic work being covered with Ivy. The circles were about 12 feet in diameter. The side borders were about 7 feet wide, and were not raised. Strips of grass 2 feet wide surround these borders, the ends terminating in tidy plants of *Yucca gloriosa*. We observed that the edgings of

these grass frameworks, as they may be called, were edged with brick laid diagonally, as shown in a previous Number of THE JOURNAL OF HORTICULTURE, forming a boundary line which could not by any ordinary amount of unskilful management get out of order. The same substantial way of securing an edging is adopted in some of the other gardens, and is well worth being extensively so elsewhere; as the brick, without showing more, perhaps, than an inch of its edge on the walk or border side, presents a formidable barrier to the hoe, spade, barrow, or roller. A white-shell walk also separates the borders from the outer grass plot by which the whole is surrounded.

The planting of the eight circular beds has been done the past summer by having four of them, A A and B B, divided into quarters by two lines crossing each bed at right angles to each other; the four other beds, C C and D D, in concentric rings or

circles. And as the planting of these beds may be of interest to our readers, we give them with some critical remarks by one well versed in such matters.

The central bed, which was much shaded with the climbing Roses, was edged with *Alyssum variegatum*; and from each recess a straight line of the same was stretched to the centre, thus dividing the bed into eight wedge-shaped panels. These panels were planted with *Gazania splendens* or *G. rigens*, and towards the latter end of the season looked very well. The *Gazanias*, however, hardly kept pace with the *Alyssum*.

The baskets A A had an edging of *Vinca elegantissima*, a variegated *Vinca*, which overhung the Ivy and rustic work with good effect. Inside this *Vinca* was a ring of *Perilla nankinensis*, and two lines of the same divided the bed into four quadrants or panels, which were planted with *Mangles' Variegated Geranium*.

The *Perilla*, by being pinched in to keep to the same height as the *Geranium*, looked remarkably well; and these beds looked well from the early part of June until November, and might be regarded as one of the most successful of the season.

Baskets B B.—Planted like the above, but plants different; the edge being a blue *Anagallis*, the inner ring and cross lines being *Geranium Flower of the Day*, and the quarters or panels *Calceolaria Prince of Orange*. In the early part of the season this looked very well; but after the middle of August there was not much flower on the *Calceolaria*, and the *Anagallis* was not showy enough to be repeated.

Baskets C C, planted in circles.—The centre (about 5 feet in diameter), *Verbena Purple King*; then a ring upwards of 2 feet wide of *Calceolaria aurantia multiflora*, and at the outside an

edging of *Tropaeolum elegans*, which, like the Vinca, overlung the edges, and the whole flowered, and were a complete mass of colour in the middle of the season, the *Tropaeolum* continuing to the beginning of November.

Baskets B, D, planted in the same manner as C, C.—The centre being *Calceolaria amplexicaulis*; then a ring of *Geranium Lady Holmsdale*, a pink-flowered variety; and an edging of a yellow *Tropaeolum*, which at one time was exceedingly rich, but, going too much to seed, was cut down in August, and flowered again in October. This *Calceolaria* is, however, late, and though indispensable in the flower garden, it is not one of the class which can be reckoned on as doing good service for five months, or longer, consecutively, which some of the varieties do.

The outer borders were planted entirely with *Geraniums*, which is the reason they were so sparingly used in the baskets. The borders, being nearly 7 feet wide, were planted in six rows: the two centre rows were of variegated *Geranium* with white leaves, then one row of a plain or horseshoe-leaved *Scarlet*, and the outer rows of *Geranium Golden Chain*, thus giving four rows of variegated *Geranium* and two rows of plain ones to each border. The central line of one of the borders was *Geranium Bijou*, with *Geranium Baron Hugel* between it and *Golden Chain*. Most people admired this; but certainly the flowers of *Baron Hugel* were dull. The other border had *Geranium Alma* for a centre, and between that and *Golden Chain* was *Geranium Judy*—a dwarf, deep rose-coloured variety with plain leaves, which, on the whole, looked better than *Baron Hugel*. The beds being some little distance apart, the slight difference in thus planting them was of no importance.

Not far removed from the basket garden is a fountain with a basin 20 feet in diameter, surrounded by a walk, and that also enclosed by a dome-shaped verandah half open. This dome is 36 feet in diameter, and the framework is well covered with *Roses*. In the distance is seen the mansion; the basket garden being also in the same direction, but nearer. This fountain is in the centre of a cross walk, having a number of flights of steps ending on the upper side in a conservatory and Dutch or geometrical garden, from whence there is an excellent view, but still better from the lower end, where, after descending some half-dozen flights of steps, we come upon another terrace-walk still considerably elevated above the ground to the south of it, and the view here being less interrupted with trees is beautiful. The park with a well-chosen piece of water stretching out seems to mingle with the adjoining country.

(To be continued.)

SHORTT'S PLAN FOR THE PREVENTION OF THE POTATO DISEASE.

ALTHOUGH not a practical gardener, yet being always interested in anything relating to agricultural pursuits, I cannot allow Mr. Pownall's observations on Shortt's treatment of Potato culture to remain unanswered, though, doubtless, there are many others who from practical experience will be able to handle the subject in a far more weighty and convincing manner.

Before Mr. Pownall thus hastily and publicly condemned this system, he should have assured himself that he had properly comprehended and thoroughly carried out the directions published by Mr. Shortt. On reading Mr. Pownall's strictures, it was very evident to me that both master and man equally misunderstood the whole matter; and it is not to be wondered at that a failure in both the plans tried by them should have been the result. Since forming this opinion I have had an opportunity of conversing with Mr. Milford, who fully confirmed me in the foregoing conclusion. It is surprising that any one can read directions so very plainly and lucidly expressed, and so completely mistake their meaning.

Mr. Milford most fully confirms all that his gardener has stated with regard to the prevention of disease by his plan. Not only on his own ground at Conter has a fine crop been realised, with hardly a vestige of the disease, but Mr. Milford states that in Norfolk, from which county he has lately returned, the most thorough and undoubted success has attended the extensive culture of the Potato on this system. My father, Mr. R. W. Fox, of Shillingford, near this city, has adopted it this last season, and reports favourably with respect to it. In the plot where the haulms were laid down and covered, there was very little disease to be found; but in another piece of ground close adjoining in the same garden, where the old system was followed,

a large proportion of the crop was severely affected.—S. BEVAN FOX, *Esq.*

Since sending off the above remarks, Mr. Shortt has called on me, and from him I learn that I have, to a certain extent, done Mr. Sanday an injustice, in ascribing to him a complete misunderstanding of the reading of the published directions. The haulm is laid evenly between and across the side of each ridge; the earth taken from the furrow is placed on the ridge, and very nearly, but not quite, covers the haulm. The tops will soon turn up to the light, and in a few days will be about half covered, and will in this state, as well as the tubers, continue to grow. If the haulm is completely covered, or if the tops are twisted together like haybands, and then covered, the disease may be arrested, but all growth in the tubers is at an end. If I understand it aright, the principle is, that the disease is not washed down among the roots by rain or heavy dews, but that wet is thrown off the ridge by the earth-covering to the haulm.

It has been thus carried out most successfully by a friend of Mr. Milford's in Norfolk for many years. The discovery was an accidental one. In making a drain by the side of a garden, the earth was thrown out over a piece of ground planted with Potatoes, the ridges of which run parallel with the new cutting. When the owner of the garden took up his crop, he found to his astonishment that all his ridges so far as the earth had been thrown out were free from disease; while all that had not been so covered were quite rotten.

POMOLOGICAL GLEANINGS.

OCTOBER RASPBERRIES.—About the first week in November last I paid a visit to a friend living near Guildford, and when looking over his kitchen garden I observed two rows of Raspberries, one on each side of a path about 10 yards in length. One row was the *October Yellow*, and the other the *October Red*. The soil of the garden, which is at the foot of St. Catherine's Hill, is of a light sandy nature, and its site warm and sheltered. The gardener said, that during the whole of the month of October they had been loaded with fruit, and that he had "gathered bushels" from them, which owing to the fineness of the weather had been of excellent flavour. These Raspberries should not be planted in cool districts. The south and east of England, and the warm valleys of Worcestershire seem best adapted for them.—RTMRS.

CABOOL GREEN GAGE PLUM.—Some four or five years since I happened to be looking over the novelties in trees and shrubs, then recently introduced at the Horticultural Society's Gardens at Chiswick. I observed among them a vigorous-growing but wild-looking Plum tree, which Mr. Gordon, who was then in the service of the Society, pointed out as the Cabool Green Gage, and, I think, hinted that it was an old favourite Plum in its aboriginal state. I at once felt highly interested, and taking advantage of my privilege as a Fellow, procured some buds. These were inserted on Plum-stocks, and the following season I had a number of young vigorous trees. Wishing strongly to see the fruit of this Plum, I potted two or three of my young trees and placed them in my orchard-house. The second year after potting one of them gave me a full crop of fruit. They were small and round, and interested me greatly. As it towards the end of July, instead of remaining green as I hoped they would, they began to turn red, and when ripe proved to be a *Mirabalon*, or *Cherry Plum*, enlarged in size. The tree is remarkable for its vigorous growth, making shoots from 7 feet to 9 feet long in one season. Its leaves are larger than those of the *Cherry Plum*, and the habit of the tree more erect and vigorous. It may, I think, be called the *Cabool Cherry Plum*, and as it seems very hardy it may prove a valuable culinary variety.—THOS. RIVERS.

TREATMENT OF OFFSETS OF GLADIOLUS BULBS.

Upon taking up the roots of *Gladiolus gandavensis* I find a large number of small bulbs, about the size of wheat grains, looking quite white and naked; also a few larger with an acorn sort of look. How shall I deal with them? I feel inclined to rub them off and plant at once; if successful my increase will be literally fortyfold. One of *Gladiolus floribundus* that I grew merely to make its acquaintance I find shooting from the young bulbs, so I have potted it.—H. B.

[In October, 1834, we had a four-hundredfold produce, like

years, of *Gladioli psittacinus*, which was selling in 1833 at 10s. 6d. the root. *Psittacinus* in strong loamy soil, or in a Vine-border in fact, produced five or six times more offset bulbs than any other kind that we know. At another lifting we had a quart-pot full of small *Gladioli* offsets not larger than rice seeds, and two pecks of the next size or sizes, for we only had two sieves to pass them through for sizing the sorts; and for fifteen years we had more or less of such fry to deal with. And the best plan we ever found was to part all the small bulbs from the large ones after they were lifted ten days, more or less, and dried in open sheds. Then the large bulbs were rubbed, cleaned, and put into paper bags; the small fry were put through different sieves to sort them into proper sizes, and to separate the soil and dust from them. Then each size was bagged in paper, and so kept till the beginning of April; then they were planted out by the thousands, in drills exactly like sowing dwarf Peas, sometimes on a Vine and Peach-border and sometimes in the open quarters of the kitchen garden. No better plan than that, as far as we know, has been hit upon since.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus, if the heat of the beds should decline, a slight lining may be added; but care must be taken that it does not heat violently. *Broccoli*, keep it free from dead leaves, as, after frost, they seriously injure the plants by causing them to rot. *Cauliflowers*, give air freely to plants under glass. *Celery*, take advantage of the first fine dry day that occurs to earth up any rows that may have overgrown the previous soiling, and be prepared to protect the ridges in case of severe frost. *Lettuce*, give air freely to the plants under glass, as advised for Cauliflowers. The glass should be merely used to exclude frost and to throw off rains, as the plants will succeed all the better in the spring for being kept hardy and stocky during the winter. To be kept free from dead leaves. *Parsnips*, where they have not yet been taken up, they should be left in the ground no longer, as they are not in the slightest degree benefited by remaining there, and should severe frost set in there would be a difficulty in getting them up. *Turnips*, on the first appearance of severe frost it is advisable to get some milder cover. They may be laid in sand after the tops are cut off. Look over root stores occasionally to see that nothing is going wrong. As we recommended last week, take advantage of frosty weather to get manure wheeled on spare ground. Trench, dig, and ridge every spare inch of ground whenever the weather will permit these operations to be advantageously performed. This is to be done more especially in gardens where the soil is of a clayey nature.

FLOWER GARDEN.

Continue planting in favourable weather shrubs, trees, Roses and Rose-stocks for future budding. Prune and nail, or tie, all climbers on walls, trellises, pillars, &c.

FRUIT GARDEN.

See that standard and other trees, which have been recently moved or root-pruned, are firmly secured against injury from winds, and also get any root-pruning or transplanting remaining to be done this season executed as soon as possible. The roots of all newly-planted trees to be secured from the effects of severe weather by mulching. Fruit trees are injured by the accumulation of moss and lichen on their branches: when the hand cannot reach it a dusting of lime will effect its destruction. Strawberries and all fruit trees in pots to be protected from frost. Take every opportunity of pushing forward pruning and nailing. Look over the fruit in the fruit-room, and remove all that are not sound. In the absence of frost, old walls may be pointed and limewashed.

STOVE.

A cautious application of fire heat must still be observed here. Keep the temperature rather low than otherwise, for fear of exciting a premature growth. Cleanliness and a judicious use of the watering-pot should be strictly attended to. A small portion of air may be advantageously admitted on fine days, and will greatly assist in purifying the atmosphere of the house. Many stove plants with large fleshy roots—such as the different varieties of *Ipomoeas*—should now be allowed to go nearly or quite dry. Great caution is necessary to provide against drip. Many *Orchids* here will make late growth in spite of system; and these, although not encouraged by improper temperatures, will be liable to rot if condensed vapour or drip be permitted to

lodge in them. The great object should be to aim at that kind of routine management which will serve to consolidate the growth already made, and to develop the blossoms of the late-flowering sorts in a proper way.

GREENHOUSE AND CONSERVATORY.

Damp and mildew are the great enemies to be guarded against here in the present state of the weather. Remove the early *Chrysanthemums* as soon as they are past their best, as the plants have but a very shabby appearance when the beauty of the bloom is over. Now is the time either to order some of the new and good sorts, or to select some of the best and most useful of your own stock, as it is better to grow duplicates of the really good kinds than to retain such as are but indifferent merely for the sake of having a long list of names. The leaves of *Camellias*, *Oranges*, &c., are liable to a dark scum, which is supposed to be a fungus. This should be cleaned away with a sponge at this period, especially as the chief interest in greenhouse plants depends in a great measure on their cleanliness. Take care during frosty weather that the Heaths do not become too dry on a sudden, or they are sure to suffer, if not killed outright. The best preventive is to be rather cautious in the application of fire heat; external coverings, where they can be applied, economise fuel and preserve the plants in a dormant state. See that the early-blooming *Cinerarias* have the lightest place in the house close to the glass; crowding is very prejudicial to this plant. Let plants of *Eranthemum pulchellum* coming into bloom have abundance of water and a warm situation. The *Veltheimias*, *Tritonias*, *Stenorhynchus speciosus*, *Lachemias*, &c., are delightful winter things. Do not water the *Pelargoniums* until they are thoroughly dry.

FORCING-PIT.

This structure must be kept fully occupied with all the different plants usually employed in forcing for the decoration of the conservatory or drawing-room. In successfully forcing many plants the application of bottom heat will be found indispensable. The great secret in the affair, if the heat be wholly composed of fermenting materials, is to keep down damp and mouldiness by an almost constant ventilation. Those who possess tank-houses or pits will pursue a somewhat different process; such will scarcely need my advice.

PITS AND FRAMES.

As the present is a very trying season for the inmates of these structures, every advantage must be taken of mild days to give air freely, and unless in very dense foggy weather, a little may be given every day when the temperature is above freezing. Little or no water will be necessary here for some time to come, as the plants will be all the better for being kept rather dry at the root, but strong healthy plants will probably require water occasionally to prevent the balls getting too dry; and when water is indispensably necessary a dry morning should be selected, if possible, for doing so and for ventilation given during the day. See that the frames are well banked up so as to be proof against severe frost, and do not neglect covering up securely at night.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

In frosty mornings wheeled fresh turfy soil and leaf mould, to give a small barrowload of top-dressing to fruit trees planted on mounds last season. Wheeled rubbish-heap to bare parts of kitchen ground preparatory to digging and trenching. Also manured flower-beds as opportunity offered. Forked up slightly among Strawberry-beds, alike to allow the rains to pass freely and to present a rough surface to the frost, before we find time to place some littery manure between the rows, and a dressing of burned earth and charred refuse over and round the crowns; as, when frost is prejudicial, it generally assails most any exposed necks that may be below the crowns. Got rid of all hauba of Peas, Scarlet Runners, all stumps of Cabbages, Cauliflowers, &c., that have done their work, and withered leaves from Scotch Kale, Brussels Sprouts, &c., that the garden may have no unpleasant smell from decaying vegetables; and took all the latter to the rubbish-heap, where they will be allowed to rot and decay, covered over with rubbish from potting-bench, &c. Trapped and poisoned mice that were threatening to make breakfasts of forward *Cauliflowers* under protection now ready for use. Sowed some *Mazagan Beans* and *Sangster's Pea*; and in pots and in rows where they can receive a little protection, *Tom Thumb*

Pea, having found them serviceable last season. Cleared away the last crop of *Dwarf Kidney Beans* sown in a cold earth pit, and covered with sashes after the middle of October: these served us for a supply to the third week in November. We used to have these vegetables during all the winter, but now we go without for two or three months, and let the coal-heap have a comparative rest. The same as respects Cucumbers, as it was found that hardly one touched them during the winter months, and to have them a place had to be heated for what in reality was not wanted. That is no reason, however, why such things should not be had by those who like them and want them, and do not mind the expense of fuel and attendance at this dull season of the year. Besides, I found that even in the case of Dwarf Kidney Beans, when presented almost constantly at the table, they were not partaken of with the same relish as when there were breaks between the times they were most plentiful in. At this season, however, I would remind beginners not to use too large pots for their Beans. I used to get most at this period from 24's and 16's, and with six Beans or so in a pot. After the middle of February and onwards 16 and 12-pots will answer best, and about three plants in a pot. Cucumbers, too, at this season should neither bear heavily nor have the fruit swelled to a large size, if it is desired to have the plants bear freely after the new year and onwards for several months. Heavy bearing in the dark months soon weakens the plants, and if weakened then it is difficult to recover them.

FRUITS.

The fruit being cut, removed some *Vines* from vinery to introduce other sorts, taking away the old soil as far as could be done without much burting neighbouring Vines, and filling up the spaces with fresh turfy loam, lime rubbish, a few bones, and a little leaf mould, and turning out the young plants at once, breaking the balls and spreading out the roots carefully and high enough to permit of sinking. Find that the extra heavy crops for twelve or ten years are telling on the Vines, as the wood is smaller than usual, though hard as a piece of Oak; and will, therefore, cut more close, and crop less next season. Filled a small Vine-pit with *Strawberries* in 48-pots, the bulk Black Prince, and the rest Keens' Seedling, setting them on boards; the Vines being laid down on the surface of the soil in a bundle until they begin to break, when the *Strawberries* must be thinned out to give them room. The *Strawberry* plants had most of the large outside boxes removed, the surface stirred with a pointed stick, the loose soil thrown off, and a top-dressing given of rich loam and dung with a little soot; any pot that was very dry was watered before the top-dressing was given. In summer and early autumn we should not think of removing one of these larger outside leaves, as then there was a reciprocal beneficial influence going on between the roots and the leaves; but now, if kept on the most of these leaves would ultimately shrivel up or wither, and be removed in the long run; whilst before that takes place they would be kept in a languid vitality by the forces of the root being partly directed to that object, instead of being concentrated in throwing up a vigorous stalk of flower-buds, and a fresh batch of leaves to keep them in company, and to organise sap suitable for both. We have tried both ways repeatedly, putting in plants with all their lower leaves remaining, though spotted and showing signs of decay, and removing the most of them, leaving only a nice tuft of fresh ones in the centre; and in every case we found the last do best. These pots and Vines average at present from 45° to 50°. The pit is just as well filled with pots as if there were not a Vine in it.

FORCING.

Lots of Rhubarb and Sea-kale have also been put in the Mushroom-house, and a bed formed chiefly of rubbish from the flower-beds, and surmounted by from 1 foot to 18 inches of tree leaves; and several inches of soil on the top have been filled with Asparagus roots brought from the open ground; it is just late enough to have it nice before Christmas, but we could not get any leaves in heat any sooner owing to reasons mentioned the other week. Looked after mice in Radish-frame, and stirred up the soil a little with the stick to keep the soil sweet, and in unison with plenty of air to keep the young plants with short stiff necks instead of long ones. Want of manure prevents us partly doing our beds in the *Mushroom-house* during summer, which we would prefer, and just adding some at this season before spawning when the heat was all right. As we make beds now, the dung is apt to be too moist for shelves; but we neutralise this by cutting some dry litter, or straw, and mix-

ing it with the dung, which when thrown into a heap dries it sufficiently—in fact, provided the dung is not too wet we hardly ever fail with Mushrooms, however heterogeneous the material we use. I detailed how nice a bed we had in summer, the bulk of which was formed of stubble, with a little short dung on the top. Could we get horse-droppings for what we want, we should prefer drying them by exposure, instead of heating them by throwing them into a heap. We have always found that the less these droppings are wasted by fermentation the longer will they produce good crops. Attended to covering, airing, potting, &c., as in previous weeks, getting forward outside work in all suitable weather.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

WINTERING A PASSION-FLOWER.—CUTTING DOWN CLIMBERS (E. B.).—There are many Passion-Flowers; some are stove plants, some are greenhouse plants, and two or three sorts of the blue Passion-Flower are all but hardy in most parts of England. Yours we take to be of the latter section, and the best way for it is to give it the winter treatment of a greenhouse, and free liberty in summer to grow in the open air, and always to be pruned at the end of October—and pruned very close indeed. All Passion-Flowers are altogether unfit subjects for dining, or any living-room cultivation, and as much so for cold pits or frames; or the more hardy kinds for pot culture at all. But, for a temporary makeshift, to keep a young Passion-Flower over one winter, the best treatment is to prune it close at the end of the oldest-wood at the end of the autumn, and to keep it half dry in a cold pit, when bedding plants would be safe till the end of the May next ensuing. Then to shake the ball of earth gently off and plant the Passion-Flower out against a south wall, or shade it with a mat, till the daytime for three weeks to keep the sun from it till the roots establish themselves in the soil. Then, to do it full justice, it ought to be watered once a week the whole of that summer till the end of August, and in November following it ought to be cut down to within 1 foot of the ground, even if it had grown 40 feet long that first season. That is the whole secret, and the turning-point in the management of Passion-Flowers, climbing Roses, Clematis, Jasmines, Honeysuckles, and all sorts of climbers whatsoever—including the *Glycine* of course. There is not one man in five hundred who can make up his mind to cut down a climber so close as that; and the first and the second season after planting, and that is the very reason why only one real good healthy climber can be met with among five hundred plants of them. Nevertheless, the law of Nature in the case of climbers is this—if you want a climber to cover a certain space in the shortest possible time you must cut it to the quick three years running. It sounds odd; but it is the truth for all that. The reasons for such treatment have been often explained in our pages.

INSECT DESTROYER (A Subscriber).—We do not know where Dupont's can be obtained. We have never seen it advertised.

WINTERING FUCHSIAS IN AN OCT-HOUSE (A Constant Subscriber).—The Fuchsias fit at all damp and set on a stone or earth floor, and the pots covered over with moss or litter, with a little water until spring, when, if all dry ones set on dry floor they will need a little water. They will keep best if dryish rather than damp; but they must not be dust dry, or the plants may die. The tops also must be protected from frost, if you do not mean to cut the plants down to the surface of the soil. One of the best modes to keep pots and tops in a cool oct-house, is to set them as close together as they will go with a partial pruning. Cover all round and over the pots with litter, and then throw a little hay all over them. A very little will secure them from frost if the place and the covering are dry. We have had them thus covered from November to March, and as then the buds begin to push, the plants require light.

VARIOUS (An Amateur Lady Gardener).—The best thing on your dry light soil would be to have your flower garden all on gravel, and to have the spaces not intended for walks in coloured gravels as at the new garden at South Kensington. The end of February will be quite time enough to plant *Cladietia brachylepis*. We heard no more of "G. D.'s" *Spergula*. *Clematis montana* will suit your object better than *Caprifolium japonicum*, and if you stretched wires against the poles for the Clematis, you might train up the Ivy to any reasonable height. We have hid cottages that way not long since. By no means turf up to the feet of the trees, they would do much better with no turf near them, but go on mulching them. Your plan for Violets and Primroses is capital; and there is not the smallest doubt about all your Roses, but in that soil get as many of them on their own roots as you can, and have nothing to do with *Spergulas* on it.

BOOK OF GARDENING (J. M.).—Buy "The Garden Manual." You can have it free by post from our office for twenty pence for twelve stamps.

NAMES OF PLANTS (A Constant Reader).—1, *Selaginella denticulata*; 2, *Selaginella* not recognised; 3, *S. Martensii*; 4, *Kalosanthes*, or *Crassula coccinea*; 5, *Sedum Sieboldii*; 6, *Cleistantha maritima*; 7, *Alcea*, perhaps a

scrap of arboresecent; 8. Saxifraga sarmentosa. (J. Smith).—1. Pteris tremula; 2. insufficient, looks like a scrap of Lastrea tridentata (Polyp. trichodes); 3. Polystichum capense; 4. Nephrodium molle; 5. Asplenium fæcidium, var.; 6. Platycladus laetata. (J. D. Dunder).—1. Geum rivale; 2. Veronica chamaedrys; 3. Hypericum pulchrum—so far as we can tell from such flowerless scraps. (M. A. S.).—It is Tussilago fragrans, Sweet-scented Coltsfoot, a native of Italy. It is sufficiently hardy to endure our winters, but then blooms early in the year and not at this season.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BIRMINGHAM POULTRY SHOW.

WE now redeem our promise of reviewing the classes of this great Show.

Our first notes are for *Silver Grey Dorkings*. If there was ever any doubt as to the difficulty of breeding these birds, this Show may dispel it. We speak on good authority when we say there were not twelve really perfect cocks in these classes. Decidedly, Dorkings are not birds of feather, and it seemed hard that an otherwise noble bird should be disqualified for a few white spots on a black breast, but it was so. Mrs. Fergusson Blair headed the first class. We congratulate that lady on the success that rewarded her enterprise in sending so far to our great Show. Ladies Bagot and Sophia Des Vaux, with Messrs. Arnold, Drewry, and Cargey also succeeded in the difficult task of satisfying the Judges in these classes. Many birds might have figured in the general competition which followed, and which was headed by Mr. Potts, of Hoole Hall. Capt. Hornby took three prizes and a silver cup, Mr. Wakefield two, and the Hon. W. W. Vernon two. All these birds were perfect, and they speak well for the strains of these gentlemen who are everywhere successful. It must not be thought these were the only birds worthy of especial mention, many of the commended and highly commended were more than meritorious. The hens and pullets were excellent, especially those belonging to Lady Louisa Thynne and Captain Hornby. *White Dorkings* were very good. Capt. Townshend and Mrs. H. Fookes deserve especial mention.

The *Spanish* fowls were very good, but there were none equal to the birds shown formerly by Mr. Davies, or last year by Messrs. Rake and Teebay. We would not attribute this to lack of merit, so much as to late moulting in the old birds, and want of age in the young. We may here remark, there was abundant proof in every chicken class that the season has been a bad one for breeding. Messrs. Martin, Teebay, Hyde, Fowler, and Rodbard were the fortunate exhibitors. In the different classes fourteen deserved degrees of commendation.

The adult *Cochin-Chinus* formed a grand display. We hardly ever recollect so good a class. The successful strains of last year were again "to the point." In old and young, Messrs. Tomlinson and Stretch were first and second, while the third went to Mrs. H. Fookes and Mr. Kellaway. The hens and pullets were good but not numerous, their quality will be proved by the names of the successful, Miss Musgrove, Messrs. Felton, Stretch, and Statham. In the adult *Grouse* and *Partridge* birds, Mr. Peepce Cartwright took all the prizes. Mr. Tudman was again first in chickens, followed by Messrs. Stretch and Felton. These were excellent classes. All the *White Cochins* prizes were taken by Mr. Robert Chase, not because there was no competition, but from the merit of his birds.

We were glad to see the *Brahma Pootras* in force, and to observe that this useful breed is now thoroughly understood and appreciated. Two excellent classes added to the success of Mr. Teebay and Lady Louisa Thynne. They were nearly all pencilled birds.

Malays were weak, and call for no particular mention.

The *Golden-pencilled Hamburgs* were very good, and some birds were of unusual merit. Here, again, the first prizes in both classes went to the same breeder. The chickens especially were beautiful; Mr. Munn's also deserve especial mention, and Mr. Clayton's. The *Silvers* do not keep pace with the Golden, Mr. Archer's secession from this breed gave it a blow it has not recovered. Nevertheless, we may speak well of the pens shown by Messrs. Martin, Harding, Munn, and Keable. *Golden* and *Silver-spangled* had been mentioned in terms of the highest praise. Many of the birds were perfect, and all those that figure in the prize list deserved the distinction. There was a richness of colour and perfection of marking in these birds that we have seldom seen equalled, and all the points that were desiderata a few years since are now attained.

Polish fowls were well represented in every class, if we look

at quality, but they were deficient in numbers. Most of the birds were perfect. Mrs. Pettat took three prizes, and received a high commendation for Golden. Mr. Dixon took six prizes in the various classes, Mr. Sugden two; and Mr. Adkins showed a pen of *Silver Polands* that reminded us of his exploits when we were some ten years younger.

The various class brought *Anconas*, *Cuckoos*, *Silkie*, *Black Hamburgs*, *Chamois*, *White Polands*, *Crève Cœurs*, and others. Many were shown in sufficient numbers to form small classes of their own. The *Cuckoos*, *Black Hamburg*, and *Crève Cœurs* are of this number.

We have now to treat of the *Game*. Every breed and every colour contributed to form these beautiful classes: one hundred and six pens and single cocks are mentioned in the prize list. The *Black Reds* are first on the list. The silver cup for the best pen of *Game* was awarded to Mr. W. Robson. He was hard run by two notable exhibitors in these classes—Messrs. Archer and Moss; the former gentleman being also the winner of the fourth prize. Mr. John Stubbs stood first for chickens. Nothing could be more beautiful than the birds in these classes. The *Brown Reds* were not behind in merit. Mr. Moss and Mr. Wood headed the two lists, and here again Mr. Archer was second. Mr. Moss took three prizes. Messrs. Cargey and Wood also were distinguished. All these pens deserve especial mention. We think we have seen the *Duckwings* better than many of those shown here, if we except one pen, which was most beautiful and perfect in colour, but the cock was disqualified for a crooked breast. The *Blacks* and *Brassy-winged* were unusually good, especially those belonging to Messrs. Burgess, Dawson, Fletcher, and Helliwell. The *White* and *Piles* were better than common, especially the latter.

This brings us to the third branch of our report—the classes for *Single Cocks*, two hundred and forty in number. *Silver Grey Dorking* cocks, *Lady Bagot*, Mr. Cargey, and Mr. Dolby took the prizes. Here again many birds that were disqualified for colour, would have figured in general competition. In the open class for the same breed, *Lady Louisa Thynne* was first, with an extraordinary bird; Messrs. Tudman and Whittington followed, and they may be proud of their victory. It was no mean exploit. We can speak in high terms of this branch of Spanish competition, the struggle was a hard one, Messrs. Lane and Harding, and Captain Heaton took the prizes with capital birds. Captain Heaton's *Cochin Cock* is one of the best chickens we ever saw, and beat even the celebrated strain of Mr. Tomlinson. It is not easy to put this latter gentleman in the second place. Mr. Craige monopolised both prizes for *Brahma Pootras*. In these classes the *Spangled* were better than the *Pencilled Hamburgs*. Messrs. W. Worrall, Fellows, Robinson, and Lady Julia Cornwallis showed the best birds. Messrs. Hindson, Grimshaw, and Moss headed the several *Game* classes with perfect birds, and good ones were thick as "leaves in Vallambrosa."

Sebright Bantams were most excellent, but few in number, Mr. Harvey Dutton Bayley took both first and both second for *Gold* and *Silver*; Mr. Hill took both third. *Black* have wonderfully improved since last year, and it would be difficult to find three better hens than those that took the prize. Perfect in colour, small sized, having good flowing tails, and perfectly white feet.

The variety class in *Bantams* showed very beautiful birds, especially some very heavily-booted speckled birds, that deservedly took prizes, nor must we except some exquisite white birds. They belonged to Messrs. Daft and Titterton.

Game Bantams are everywhere numerous, and this Show formed no exception. Many figured in the prize sheet, and many more deserved to do so. The printed list must speak for their merits, our space will not allow us to enumerate all that were worthy.

Although we have seen heavier pens than those that took the *Aylesbury Duck* prizes, yet we never recollect a heavier average of a number of birds. The prize pens weighed 24½ lbs., 22½ lbs., and 22 lbs. All were well chosen and well-conditioned birds. There were forty-three pens of *Rouen Ducks*, an excellent class of first-rate birds. They are fast increasing in weight. The prize pens weighed 21½ lbs., 19½ lbs., and 19½ lbs. There were lots of birds in this class that weighed more than 6 lbs. each, and when people accustomed to see only and to recollect the three or four prize pens, birds of amazing weight, are disposed to think nothing of Ducks that weigh only 6 lbs. each, let them recollect what they need to be. The class for *Buenos Ayrean Ducks* has realised the anticipations of its projectors, not only

in numbers, but in the quality of its birds, and in the proof afforded at each succeeding Show, the amateurs of this beautiful breed understand them. Thus we had them smaller at Birmingham than we have ever had them. *Call Ducks*, both White and Brown, with *Mascovies*, made up the variety class. But the ornamental birds comprised *Mandarins*, *Carolinas*, *White-eyed Brahmas*, *Swains*, *Wild Ducks*, and a pair of most beautiful *Sabastopol Geese*. These latter birds are curious in the extreme. From the tops of the wings and the extremities of the wing-feathers, large bunches of beautiful white feathers hang curling, twisting, and lying about like shavings. If they are found to be good breeders, they will become popular.

Dismissing from our fancies, we come to the sober bird of which it is reported Queen Elizabeth said, "It was foolish; too much for one, not enough for two." There were no poultry shows in those days, and it was a tolerable Goose that weighed 5 lbs. on the table. Deduct bones, skin, and fat, and there would remain but little. If good Queen Bess could return, and if she ordered a brace of *Geese* for herself and another, she would marvel if two of Mr. Fowler's were brought—the three weighed 70 lbs.; or if Mrs. F. Blair's, that weighed 20 lbs. each. Others weighed well, but birds of 18 lbs., and in some cases of 20 lbs., had to be content with a high commendation. The heaviest weights are always among the grey birds, they seem to make about 5 lbs. more per head than the white ones. Fifteen prize pens of *Geese* weighed, the forty-five birds, nearly 900 lbs.

The *Turkeys* ran each other closely. The difference between the first and third prize birds in Class 91, was only 1½ lb. The nine birds in the three pens weighed 160 lbs. In Class 92, the nine birds weighed 144 lbs. We can speak most highly of the condition of many of these.

Thus ends our report of this great Show. We shall have to return to it, but my now content ourselves with saying, everything was as usual well managed. The members of the Council were always at their post, and nothing was neglected that could add to the comfort of the visitors, or the well-doing of the competing animals.

Messrs. Shackel, Luekrook, Matthews, Wright, J. Love, Adkins, Mapplebeck, Cattell, and others, were in attendance during the whole of the Show, and deserve the warmest thanks of every one who takes an interest in this great Exhibition.

Having published a list of the prizetakers last week, we now only add the names of those who had commendations.

DORKING (Silver Greys).—*Chickens*.—Commended, Countess of Chesterfield.

DORKING (Coloured).—Highly Commended, Hon. W. W. Vernon; T. W. Hill; E. Whitaker. Commended, H. W. B. Berwick, *Chickens*.—Highly Commended, A. Potts; Mrs. Pettat; Mrs. F. Blair; E. H. Geary; J. Robinson; Mrs. F. Arkwright; J. Shaw; W. Siddon. Commended, Mrs. F. Arkwright; E. Shaw; Mrs. F. Blair; H. W. B. Berwick.

DORKING HENS.—Highly Commended, Marchioness of Winchester; E. H. Garraud; H. Lingwood; J. Smith. Commended, W. Southam. **Pullets.**—Highly Commended, Mrs. Hanbury; C. H. Wakefield; J. Smith. Commended, Lady Bagot; Mrs. Bromley; H. Lingwood; W. Bromley.

DORKING (White).—Commended, Mrs. F. Blair; H. Lingwood. *Chickens.*—Highly Commended, Mrs. H. Fookes; J. Robinson, Mrs. A. Beardmore.

SPANISH.—Highly Commended, Miss M. L. Rake; W. R. Prill. *Chickens.*—Highly Commended, Miss M. L. Lake; A. Campbell; R. W. Boyle; R. Tebbay; J. Smith; W. R. Bull; H. Lane. Commended, J. W. Smith; J. E. Fowler; J. Martin. *Hens.*—Commended, Mrs. L. C. Stove; J. H. Craigie.

COCHIN-CHINA (Cinnamon and Buff).—Highly Commended, Miss V. W. Musgrove; H. Bates. Commended, C. Felton; H. Tomlinson. *Chickens.*—Highly Commended, C. Felton; S. Statham. Commended, Mrs. Herbert; H. Bates. *Hens.*—Highly Commended, H. Bates. Commended, Mrs. E. A. J. Fox. **Pullets.**—Highly Commended, H. Bates; S. Statham.

COCHIN-CHINA (Brown and Partridge-feathered).—Highly Commended, Mrs. Herbert. *Chickens.*—Highly Commended, J. B. Walthew; Miss V. W. Musgrove; J. Cartwright. Commended, D. S. Moore; J. Hindson. *Hens.*—Commended, P. Cartwright. **Pullets.**—Highly Commended, C. Felton.

COCHIN CHINA (White).—Highly Commended, C. R. Titterton. Commended, W. Dawson. *Chickens.*—Highly Commended, W. Dawson; C. R. Titterton. Commended, Mrs. F. Blair; C. R. Titterton; R. Chase.

BRAMA POOTRA FOWLS.—Commended, J. H. Craigie. *Chickens.*—Highly Commended, Mrs. F. Blair; C. H. Adams. Commended, Mrs. E. Tebbay; Mrs. F. Blair.

MALAY.—*Chickens.*—Highly Commended and Commended, C. Ballance. **HAMBURGERS (Golden-pencilled).**—*Chickens.*—Highly Commended, J. Mann; Carter and Vallant; W. Kershaw. Commended, Rev. N. Gresley; Carter & Vallant.

HAMBURGERS (Silver-pencilled).—Highly Commended, W. H. Kerr. *Chickens.*—Commended, D. Harding; W. H. Kerr.

HAMBURGERS (Golden-pencilled).—Commended, W. B. Lane; H. Corlor. *Chickens.*—Highly Commended, W. Kershaw. Commended, W. C. Worrall; J. A. Sheroff.

HAMBURGERS (Silver-pencilled).—Highly Commended, Mrs. Pettat; H. Carter. Commended, H. Tebbay. *Chickens.*—Highly Commended, Mrs. Pettat; J. Fielding; J. A. Sheroff. Commended, G. C. Hardman; D. Harding; H. Ecal. *Hens.*—Commended, W. Kershaw; G. C. Hardman.

POLISH (Black with White Crest).—Highly Commended, G. Ray. **POLISH (Golden).**—Commended, Mrs. Pettat. *Chickens.*—Commended, J. Dixon.

POLISH (Silver).—Commended, Mrs. Pettat; G. C. Adkins; R. W. Boyle. *Chickens.*—Commended, H. Beldone.

OTHER DISTINCT VARIETIES.—Highly Commended, Countess of Aylesford (Cuckoo). Commended, Rev. P. H. Nind (Black Hamburgs); Lieut.-Col. Clowes (Andalusians); W. Dawson (Sulans).

GAMES (Black-breasted and Red).—Highly Commended, Hon. W. W. Vernon; G. Swift. Commended, S. Grimshaw. *Chickens.*—Highly Commended, W. Cox; E. R. Swift; E. Archer; W. Robson; S. G. Holtom; J. Smith. Commended, J. P. Smith; N. Grimshaw; J. Stubbs.

GAME (Brown and other Reds).—Highly Commended, E. Archer; W. Dawson; T. Burgess. Commended, S. Grimshaw; T. Burgess; jun.; R. I. Robinson; G. Cargy; G. W. Moss; G. E. Meredith; J. Deucester. Commended, A. B. Dray.

GAME HENS (Black-breasted and other Reds).—Commended, E. A. Cottrell; J. Hens. Highly Commended, G. W. Moss; R. A. Cottrell; J. Morris. Commended, H. W. Walker.

GAME (Duckings and other Greys and Blues).—Highly Commended, G. Bradwell; W. Dawson. *Chickens.*—Commended, Marquis of Hastings; G. Bradwell; T. Catless.

GAME (Green and Brass-winged, except Greys).—Highly Commended, H. Lowe; J. Harrison; F. Mann. *Chickens.*—Highly Commended, W. Dawson. Commended, H. Lowe.

GAME (White and Piles).—*Chickens.*—Commended, J. Fletcher. **Pullets, except Reds.**—Highly Commended, T. T. Barnan. Commended, J. Hope.

SINGLE COCKS.

DORKING (Silver Grey).—Highly Commended, Earl of Chesterfield; Lord Bagot. Commended, W. Bromley.

DORKING (Except Silver Grey).—Highly Commended, Hon. W. W. Vernon; T. W. Hill; Rev. C. D. Hewson; E. Shaw; Mrs. Pettat; E. H. Garraud; T. L. Brown. Commended, Rev. J. G. A. Baker.

SPANISH.—Highly Commended, C. R. Titterton; J. W. Smith; T. P. Wood, jun.; R. Tebbay; Rev. C. Lowndes; R. Falon. Commended, Miss M. L. Lake; J. W. Smith.

COCHIN (Cinnamon and Buff).—Highly Commended, Mrs. H. Fookes. Commended, H. Bates.

BRAMAS.—Highly Commended, Mrs. F. Blair. Commended, R. Tebbay. **HAMBURGERS (Golden-pencilled).**—Highly Commended, G. H. Wakefield.

HAMBURGERS (Silver-pencilled).—Commended, D. Harding. **HAMBURGERS (Silver-spangled).**—Highly Commended, H. Carter. Commended, J. Dixon.

POLISH.—Highly Commended, C. J. Samuels. Commended, Mrs. Pettat. **POLISH (White, Piles, Duckings, and others, except Red Game).**—Highly Commended, J. Deucester; H. Lowe; H. Worrall. Commended, G. Ray; J. Peacock.

POLISH (Black-breasted Reds).—Highly Commended, E. Lister; W. R. Lane; J. Smith; J. O. G. Palmer; J. Ory. Commended, W. Robson; E. Archer.

POLISH (Brown and other Reds).—Highly Commended, G. W. Moss; T. Burgess, jun. Commended, J. Chorce jun.; R. Adeock.

BANTAMS (Black-legged).—Highly Commended, J. W. George. Commended, J. George; J. Ory.

BANTAMS (Black-breasted and other Kod Game).—Highly Commended, E. Cope; T. H. D. Bayley; J. Camm; H. Shield; J. Holme; M. Turner.

BANTAMS (Game of other Varieties).—Highly Commended, Miss V. W. Musgrove; R. Hawkins, jun.; J. Camm; W. Silvester. Commended, Miss V. W. Musgrove; W. Silvester.

BANTAMS (Game Cocks).—Highly Commended, H. Hawkesley jun.; T. H. D. Bayley; J. Camm. Commended, T. H. D. Bayley.

DUCKS (Aye-bury).—Highly Commended, Duchess of Marlborough; J. K. Fowling. Commended, J. W. George; Mrs. M. Scammons.

DUCKS (Domen).—Highly Commended, Mrs. F. Blair; A. Campbell; H. Worrall; W. H. G. K. Emington; R. Hawksley, jun. Commended, W. Joshua; W. H. Denison; H. Worrall.

DUCKS (East Indian).—Highly Commended, Miss Clifton; J. Martin; C. Baker; P. W. Earle. Commended, Rev. T. Green; J. W. Smith.

DUCKS (Any other Variety).—Highly Commended, E. H. France (White Call); R. W. Boyle (Bahama); W. Joshua Wild.

GEESSE (Grey and Mottled).—Highly Commended, Marchioness of Winchester; W. Kershaw. **Goosings.**—Highly Commended, Sir R. Peel. Commended, Mrs. M. Scammons.

TRUCKYS.—Highly Commended, Mrs. Sherratt; T. Satchwell. Commended, Marchioness of Winchester. **Poult.**—Highly Commended, T. Satchwell; Rev. T. L. Fellowes; J. Smith. Commended, Mrs. F. Blair; E. Guy; J. Peacock.

TRICOONS (Carpies).—Highly Commended, J. Smith. **Almond Timblers.**—Commended, G. F. Nichols; A. L. Silvester. **Balds.**—Commended, S. Shaw. **Jacobins.**—Highly Commended, J. T. Lawrence. Commended, G. F. Nichols; H. Bates. Highly Commended, G. F. Nichols; Cook. Highly Commended, G. C. Adkins. Commended, J. T. Lawrence. **Trumpeters.**—Highly Commended, W. H. C. Oates; S. Shaw. Commended, G. C. Adkins; D. Thwaites. **Doaners or Crappes.**—Highly Commended, T. Rüdth.

North Timblers.—Highly Commended, G. F. Nichols. **Orts.**—Very Highly Commended, H. Morris; McGregor. **Beaks.**—Highly Commended, E. Elze. **Turkies.**—Commended, G. F. Nichols. **Borks.**—Highly Commended, McGregor. **Rake; P. Eden.** Commended, G. G. Felton. **Teants.**—Highly Commended and Commended, G. C. Adkins. **Dragoons.**—Highly Commended, H. Y. de la Motte. Commended, S. Shaw; C. Felton. **Other Varieties.**—Highly Commended, H. Morris; A. G. Brooke (Wonga-Wongs). Commended, E. A. Hargrove (Fribbaks); S. Shaw.

THE JUDGES OF POULTRY were—the Rev. R. Pullin; G. J. Andrews, Esq.; Mr. Bailly; and Mr. Chalfour. And of Pigeons, Mr. H. Weir, Lyndhurst Road, Peckham, London; Mr. T. J. Cottle, Pulney Villa, Cheltenham.

THE BATH AND WEST OF ENGLAND SOCIETY have fixed their next exhibition, at the city of Wells, for the 27th, 28th, 29th, and 30th of May next.

WINTER-LAYING POULTRY.

I SOMETIMES see in the Journal inquiries relative to the winter-laying qualities of different breeds of poultry. I have always found that the cross between the Spanish and Cochon produce the best layers. These pullets again crossed with Black Hamburgh are first-rate layers. I prefer the Black, as they are better layers than the Golden-spangled, and lay larger eggs than the Silver-spangled. I set aside the Pencilled, as they lay such small eggs.

The best layer I ever had was one of the last-named cross. She was hatched on the 18th of March, 1858; laid her first egg on the 1th of August, and on the 17th of November had laid eighty-one eggs. She then stopped, and partially moulted. She began again to lay on the 25th of December: her eggs were large, and one of the eighty-one was double-yolked. After this I did not keep an account of her eggs; but she continued laying the whole of the spring and summer with very little interruption. In the autumn she became broody, and moulted.

She is still living, and is the best layer in the yard, and her eggs are very large.—J. L.

FOOD FOR POULTRY.

IN looking through "Our Letter Box" of your impression of November 26, I find under the head of "Food for Hens," you recommend to your correspondent ground but dressed oats as food for Cochon-China fowls, that being the best to cause them to lay the winter through. Now, if for my part have been attending to the directions given in your "Poultry-Book for the Many," which states that potatoes, barley-mead, bran, and rice, should in certain proportions be mixed and given twice a-day, and whole barley on noon.

I have what I believe to be the pure Cochon-China fowl, and giving them the food as above, under the impression that I shall in due time be rewarded by a fair supply of new laid-eggs. Am I right in my supposition, or must I have recourse to the oats in lieu of the potato food, &c. I do not see that the manual speaks of the dressed oats as food. If you will kindly answer my query in your next impression you will greatly oblige.—ONE IN DOUBT.

[For poultry breeding-stock, the object to be aimed at is healthful vigour, well-developed muscles, and very little fat. To secure this, it is desirable that the poultry manager should have at his command barley, boiled potatoes or rice (we prefer the former), bran, and ground barley or ground oats (the latter for choice, though both are nearly equal in nourishing power). In cold weather or when the fowls seem too thin, or out of condition, give chiefly ground oats or ground barley, and whole barley. In hot weather, or if the fowls show symptoms of too much fat, give more boiled potatoes and bran and less of corn in any form.

No high feeding will make old hens lay in winter. Early pullets will do so naturally if in vigour, and the laying may perhaps, be accelerated by a very little bread soaked in ale; but over-stimulating them is bad management.]

CRYSTAL PALACE WINTER POULTRY SHOW.—The following are the number of pens taken in each class at this Exhibition, which opens to-morrow:—Spanish, 92; Pouter, 187; Cochon-China, 91; Brahma Pouter, 21; Game Fowl, 183; Hamburgs, 116; Polish, 24; Malay, 11; Other Varieties, 23; Bantams, 79; Geese, 7; Ducks, 41; Ornamental Water Fowl, 3; Turkeys, 23; Gold, Silver, and other Pheasants, 6; Pigeons, 314; Rabbits, 110. Total, 1331.

ABERDEEN POULTRY SHOW.—We have received a schedule of this Exhibition, to be held on the first and second days of January next. The classes are certainly somewhat limited, and the premiums offered are not of great amount; still perhaps quite as much as the requirements of a first show call for. On future occasions, should success attend the coming meeting, no doubt the prizes will be increased in value, and certainly the attempt to establish a poultry show so far north as Aberdeen proves that the taste for poultry culture is even yet extending. In the Pigeon classes we notice a premium offered for Ruffs; we presume it is intended for Jacobins. It is our conviction the classes for Single Cocks at Aberdeen will prove a failure, the premium offered

being only 10s. to each of the four varieties selected—viz., Spanish, Dorking, Cochon-China, and Game fowls, subject to this condition: "Entry money for the single cocks, 2s. 6d. each, and not less than four of each breed to form a competition." Surely after paying 2s. 6d. entry, and carriage, the only inducement here left by such contingency, is for amateurs to compete simply for the honour of mastery; if any prospect of gain being almost hopeless. We wish the promoters success, and doubtless another year the prize list will be revised.

MR. TATE'S DEFENCE, AND SOME FACTS IN REPLY.

It is an old and true saying that "he who is first in his own cause seemeth just." I have been much surprised at a one-sided statement which has appeared in your Journal regarding a transaction between Mr. Sandford, of Plymouth, and myself; and as you have permitted him to state his case, I trust that, in common fairness, you will allow me to state mine, that the public may judge between us, and I be relieved of a charge, which is at least covertly laid against me—viz., that of a swindler.

Mr. Sandford made me an offer of a pen of Duckwings, a pen of Black Red Bantams, and two Spanish pullets for the Black Red Game cock and the pen of Duckwings advertised. I accepted that offer, providing he would send me his birds on approval, to which he agreed. As several days elapsed without my either hearing from him or receiving the birds, I again wrote, asking whether he really wanted my birds. He then sent me the Black Reds, and, in place of the Duckwings, two blue-legged Black Red pullets and one hen; the three birds worth about 7s. 6d., whereas he considered the Duckwings worth about £1 10s.

A few days after the birds arrived, Mr. Sandford wrote to me, saying he had sold the Duckwings, and had sent me the others, which, if not approved of, I was to return. I considered he ought to have written to me before sending them, and have told me he had sold the Duckwings, inasmuch as they were the birds I especially wanted. Did he not fasten the bargain by sending the Black Reds, as it was part of the contract?

When I wrote telling him the Duckwings were all I cared for, he replied that I might have them for £1 10s., and yet in a previous letter he asserted they were sold; and I find also he has since exhibited them more than once.

The place from whence Mr. Sandford's letters are dated (Manchester) and the letters themselves would prove him to be a highly respectable man, and a person of education. I do not know by what name they would characterise such conduct in polite circles, but I do know what we should call it in Yorkshire.

I am quite ready to allow any unprejudiced person to judge between us or the correspondence. If it be proved that I have acted dishonestly I will apologise, and make any just reparation to Mr. Sandford; but should it be given in my favour I certainly shall expect him to do the same to me.—ROBERT TATE, Driffeld.

We forwarded Mr. Tate's letter to Mr. Sandford, whose observations upon it are as follows:—

"Since the publication of my letter in THE JOURNAL OF HORTICULTURE, I received a letter from Mr. Tate, saying he would forward me the Birmingham Black Red cock, and a hen to match, as soon as he returned from the Darlington Show, for which he was entered for the sweepstakes. I immediately answered his note, stating that I would have nothing more to do with him, and the only way for him to get out of the scrape was by returning my Bantams, or £3, for I found since my letter was published, that he had actually sold the Black Red cock to Dr. Shaw, of Kirkham, at the very time he offered it to me. Now, in my last letter to him declining to have anything more to do with him, I really could not help pitying a man who would place himself in such a position, and I told him if he would do as I wished, I would not publish his correspondence with Dr. Shaw on the subject. His answer to me is, that Dr. Shaw never had the bird, but that he had started it off to me that day with a hen to match, and he hopes this would compensate me for the Bantams.

"It is needless to point out to you that he has either swindled Dr. Shaw, and sent me the birds, or has done us both, which I expect is about the truth, as Dr. Shaw observes it is just possible you will find many parties think themselves the happy possessors of this identical bird. Dr. Shaw, of course, as you

will see by the letter I enclose, paid 30s. for the bird, as the second in the sweepstakes last Birmingham Show, then belonging to Swift. Mr. Tate's answer to me on my pointing out the discrepancy in the transaction as regards his offering me the bird when it was already sold to Dr. Shaw, and in his possession, I think is rather characteristic. 'Dr. Shaw was satisfied, and that was enough, the bird was not the Birmingham bird, but one of Swift's breed.' I should tell I received a cock bird and a hen on Saturday from him, in spite of my remonstrance. I need not tell you the bird he sent me no judge ever awarded a prize to in his life.

'Now, I should not have troubled you with these remarks, which I send for publication, had not Mr. Tate thought proper to justify his conduct in this transaction. As to his remarks respecting my having sold the Bantams, to which he was entitled, it is a very lame excuse, as he owns himself in his letter to you that he had only to return the birds I had sent him, if he did not approve of them; and as to the description he gives of them, I think the best arguments I can put forth, that the birds were really excellent, is, that Mr. Tate would not return them, although frequently solicited by me to do so; but he preferred sending me the Birmingham sweepstakes cock.

'You will see by the dates of the enclosed letter, that the very time he was in treaty with me for the disposal of this bird it was the property of Dr. Shaw.

I think this will answer Mr. Tate's remonstrance to you. It is immaterial as to the locality, but I think there can be but one name for the transaction.

'As regards Mr. Tate stating that I offered him the Duckwing Bantams for £4 10s., after I stated they were sold, the accusation is simply absurd. The pen I offered him for that price was my best birds, and I have exhibited them frequently with success. The birds I sold are now in the possession of a party in Devonport, and were certainly inferior to the ones I offered to sell for £4 10s.—V. SANDFORD.'

[We have seen Mr. Tate's letters to Mr. Shaw, and to Mr. Sandford, and they fully sustain all which the latter has stated, and something more. These facts coupled with those stated in Mr. F. Baily's communication last week, and the events of former years, we hope will place Mr. Tate in a true light before our readers. We hope that both Mr. Shaw and Mr. Sandford will give directions to their solicitors to proceed in any way they may consider the facts justify. We know how we should proceed.]

THE RABBIT (LEPUS CUNICULUS): ITS HISTORY, VARIETIES, AND MANAGEMENT.

(Continued from page 80.)

MANAGEMENT.

CHOICE OF BREEDING STOCK.—The females should be physically strong, the body long and well developed, the hind legs large and well apart, teats apparent, even when not pregnant, and filled with milk at the approach of birth. The doe should not be allowed to breed at less than six months old, although they may engender at five months; but it is better, if you wish to preserve a fine race of Rabbits, to wait till they are eight or nine months old, before you allow them to bear. If under six months they would only produce weak and delicate young ones. Indeed Nature, with all her efforts, could not suffice for the development of the mother, and give the nutrition necessary for the young at an earlier age.

As the choice of the female is important, that of the male is not less so. The buck should possess the same physical proportions as the female, with the addition of a larger head and body, and should be at least eight or nine months old, and if well taken care of, he will continue to produce fine vigorous young ones till four or five years old.

The most gentle and tame females should be chosen, as the turbulent often destroy their young; but the males should be hardy, bold, and vigorous.

SIGNS OF HEALTH.—Both males and females should be moderately fat, their fur sleek and shining, their eyes bright, and their dung dry and hard.
